

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

INDEX.

VOL. LXXXI NEW SERIES. (VOL. CXXXII OLD SERIES.)

JANUARY TO JUNE, 1906.

- Abdominal adhesions, 510
Abdominal neuralgia, 155
Abdominal route in operation for uterine cancer, advantages of, Dr. Scharlieb, 551
Aberdeen University, 405
Aberdeen's Lord Rector, 245
Abortifacients' methods, 114
Abstracts of practical papers, 1
Academic medical costume, 678
Acute poisoning, 345
Activation of pancreatic juice by calcium salts, 645
Action against a medical man, 377
Action of slander, 428
Action of tubercle bacillus preparations, 344
Acute abdominal diseases, Dr. Barling, 603
Acute alcoholic poisoning, 57
Acute angio-neurotic oedema, 238
Acute cholecystitis in the periperium, 406
Acute chorea, Dr. Sullivan, 280
Acute herpiform stomatitis, Drs. Weber and Furth, 574
Acute intestinal obstruction, 485
Acute nephritis, 286
Acute neuritis of brachial plexus, 277
Acute rheumatic arthritis, 564
Acute uræmia, 494
Addison's disease, 26, 673
Addison's disease, Dr. Gullan (illustrated), 457
Illustrated to Lord Lieutenant by E.C.F.I., 184.
Adeno-carcinomatous tumour, removal of, Dr. Macnaughton-Jones, 498
Administration of anaesthetics by dentists, 47
Administrative control of phthisis, 317
Advanced carcinoma of both ovaries, Dr. Jellett (illustrated), 307
Advanced syphilis of the cerebral arteries, 371
Agglutination by the serum in tuberculous pleurisy, 644
Aid for consumptives, 205
Albuminuria in pregnancy, 295
Alcohol and insanity, 269
Alcoholic craving, the, Dr. Campbell, 391
Alexander, Dr., maternal function and the national life, 94
Alice in Blunderland, 409
Aliens Act, the, 5
Aliens in the Port of London, 210
Alleged bogus doctor, 158
Amalgamation of the London medical societies, 29
Amaurosis following the injection of paraffin, 160
Amaurosis after paraffin injections, 507
Amateur X-ray treatment, 241
Amber and lady doctor, 650
Amenorrhœa associated with serious eye symptoms, 618
American form of gout, 461
American in Harley Street, an, 624
American preserved meats, 598, 671
Amputation of the thigh, 322
Anastomosis, 101
Ardouard's beef powder, 77
Aneurysm of the right radial artery, 102
Angiomatous fibroma of the uterus, 618
Annual council election, R.C.S. Eng., 642
Annual dinner of the association of medical diplomates of Scotland, 237
Annual report of University of Edinburgh, 75
Another cure for sea-sickness, 515
Another hospital "scandal," 462
Anthrax, 192
Anti-enteric inoculation, 456
Anti-liver serum, 260
Antiseptic ointment, 371
Antiseptics in medicine, 410
Anti-typhoid inoculation in the Army, 543
Anti-typhoid serum, 538
Anti-vivisection strategy, 244
Antwerp international exhibition, 53
Aortic aneurysm, 75
Apothecaries' Hall of Ireland, 78, 135, 225, 685
Appendicitis complicating pregnancy and parturition, 406
Appendicitis due to oxyurias vermiculosis Mr. Carson, 303
Appendicitis, early operative treatment of, Mr. D. Kennedy (illustrated), 629
Appointments—end of each No. Army medical reform, 677
Army medical service, 159, 624
Are doctors greedy? 649
Army surgeons and professional secrecy, 382
Arany, Dr., dietary in diabetic gout, 66
Arsenic and iron, 664
Arsenic in beer, 163
Arthritis deformans, 673
Ascites and Talma operation, 181
Ascites in women, 73
Asher, Dr., uterine suspension, 467
Aspergillus niger, 645
Atypical leukæmia, 564
Axillary and pectoral cicatrices following removal of the breast, 161
Babes and sucklings, 353
Bacteriological examination of specimens, 21
Bacteriology of acute rheumatism, 212
Bacteriology of a common cold, 538
Bacteriology of empyema, 213
Bacteriology of puerperal infection, 511
Bacteriology of peritonitis, 295
Bacteriology of summer diarrhoea in infants, 538
Bacteriology of aural and nasal discharges, Dr. Lewis, 588
Bald novelists, 436
Ball, Dr., modern treatment of gonorrhœa, 494
Bandl's intra-uterine sound (illustrated), modification of, 123
Banquet of L.R.C.S.Eng., 563
Bantl's disease, 637
Bar v. medicine, 597
Barbers' Itch, 29, 412
Barling, Dr., acute abdominal diseases, 603
Basedow, 614
Basedow's disease, 46, 74
Beard, Mr., profuse disquamation in typhoid fever, 278
Behring's, Prof., "Tuberculase," 165
Belfast, health of, 481, 615
Belfast hospital for sick children, 132
Belfast maternity hospital, 232
Belfast ophthalmic hospital, 428
Belfast water supply, 288
Bennett testimonial fund, 3.
Requests to medical charities, 349
Berl-berl, 115
Berlin doctors' incomes, 131
Birmingham Benevolent Society, 617
Births—end of each No.
Biter bit, the, 297
Blasenon case, the, 675
Bogus death certificates, 189, 211
Bone callus, 231
Boot's stores and ammoniated quinine, 24
Boric acid in sausages, 24
Borofax (illustrated), 670
Bovine tuberculosis, 236
Black water fever, 636
Blood of epileptics, the, 322
Bloodless duel, a, 462
Bradycardia, Dr. Finny, 442
Breach of bar etiquette, 567
Bristol bogus doctor fined, 190
Brighton Council's consumption scheme, 404
British dumping ground for American quacks, 143
British gynæcological society, 105
British medical association and its charter, 350; Toronto meeting, 648
Branched diabetes, 456
Budget, the, 460
Bullet wounds, 371
Calcium chloride in the treatment of headaches, 456
Cambridge long vacation courses, 536
Campbell, Dr., the alcoholic craving, 391
Campbell, Dr., inguinal hernia in children, 496
Cancer, 587
Cancer hospital, London, 265
Candidates and physical deterioration, 57
Capeuloids, 299
Carcinoma, 531
Carcinoma cutis, Dr. O'Brien, 421
Carcinoma of the breast, 160
Carcinoma of the penis, 697
Carcinoma of the thoracic duct, 136
Carcinoma of the uterus, Mr. Jessett, 195
Care and control of the feeble-minded, 509
Care of the feeble-minded, 185
Carmichael, Mr., inguinal hernia in a female, 523
Carnegie trust, 459
Carson, Mr., appendicitis due to oxyurias vermicularis, 303
Castor-oil powder, 508
Catgut sterilisation, 231
Catholic University School of Medicine in Ireland, 694
Caustion of insanity, 233
Caustion of punctiform hæmorrhages in the appendix, 697
Caustion of syphilis, 213
Census of the Empire, 269
Central criminal court, 321
Central midwives board, 129, 229, 370, 425, 478, 505, 580
Central midwives board again, 111, 353
Central midwives board and illiterate nurses, 409
Central midwives board and its relations with Ireland, 460
Central rupture of the perinæum, 511
Cerebellar tumour, 131
Cerebral abscess, Dr. Dardenne, 553
Cerebral diplegia, Dr. Palmer, 364
Cerebral tumour, Dr. Guthrie, 150
Cerebro-spinal meningitis, 213, 230
Certain appearances of X-rayed hairs, 238
Cervical rib with resulting gangrene of the fingers, 266
Chalky metastases in the heart, 399
Chapped hands, 130
Chemical and physical society, 617
Chemists doing the work of medical men, 241
Chemist's error, a, 297
Chemists' exhibition, 454
Chemist's fatal error, a, 4
Chemists' shops and limited liability companies, 218
Chemists' war, the, 541
Childbirth after colotomy, 295
Children and sexual questions, 166
Chinese labourers and sanitation, 327
Chivers' preserved fruits, 375
Chorioid sarcoma, 484
Christian scientists' privileges, 218
Christian science, 514
Chronic abscess in the chest wall, Mr. P. Beale, 41
Chronic alcoholic leptomeningitis, 243
Chronic acetanilide poisoning, 238
Chronic cure, a, 570
Chronic diarrhoea, Dr. Hutchison, 360
Chronic diarrhoea simulating sprue, Dr. Sullivan, 363
Chronic impetigo, 101
Chronic latent appendicitis, 564
Chronic pancreatitis, 55
Cicatricial stenosis of the pharynx and larynx, 46
Cinematograph in medicine, 459
Cinematograph as a means of clinical teaching, 589
Circumscribed abscess of bone, 539
Cirrhosis of the pancreas in diabetes, 673
Clairvoyance, 597
CLINICAL LECTURES.
Acquired flat-foot, Mr. Mitchell, 332
Alexander, Dr., cancer of the uterus, 358
Angina pectoris, true and false, Prof. Bouchardt, 302
Atkins, Dr., hæmaturia of renal organs, 438
Beddard, Dr., cough, 600
Bewley, Dr., syphilitic pseudo-general paralysis, 144
Bouchardt, Prof., angina pectoris, 302
Cancer of the uterus, Dr. Alexander, 358
Cause and therapy of elephantiasis, Dr. Kuhn (illustrated), 246
Clinical examination of the blood, Dr. Whiting (illustrated), 680
Conjunctiva, inflammation of the, Dr. Ramsay, 626
Cough, Dr. Beddard, 600
Cystic degeneration or transformation of the kidneys in the adult, Dr. Steven, 492
Dagan, Dr., secretory neurosis of the stomach, 220
Diagnosis and treatment of cancer of the stomach, Mr. Mayo-Robson, 6
Diagnostic value of alterations of the pulmonary second sound in cardiac disease, Sir C. Nixon, 34
Essential nephritic hæmorrhage, Prof. Schuller, 62
Fractures of the shaft of the femur, Dr. Haughton (illustrated), 386
Gibson, Dr., persistent ductus arteriosus, 572
Gonorrhœal rheumatism and gonococcal infection, Dr. Murrell, 168
Hæmaturia of renal origin, Dr. Atkins, 438
Haughton, Dr., fractures of the shaft of the femur (illustrated), 386
Herschell, Dr., routine examination of the faces, 274
Hemiplegia, Dr. A. Whiting, 194
Indications for operation in appendicitis, Dr. Maunsell, 90
Jellett, Dr. H., pelvic tuberculosis, 652
Kuhn, Dr., cause and therapy of elephantiasis (illustrated), 246

Lindsay, Dr., malignant disease of the lungs, 546
 Malignant disease of the lungs, Dr. Lindsay, 546
 Maunell, Dr., indications for operation in appendicitis, 90
 Mayo Robson, Mr., the diagnosis and treatment of cancer of the stomach, 6
 Mitchell, Mr., acquired flat-foot, 332
 Mitral stenosis, Dr. Rolleston, 414
 Murrell, Dr., gonorrhoeal rheumatism and gonococcal infection, 168
 Newbolt, Mr., tropical abscess of the liver (illustrated), 518
 Nixon, Sir C., the diagnostic value of alterations of the pulmonary second sound in cardiac disease, 34
 Pelvic tuberculosis, Dr. H. Jellett, 652
 Persistent ductus arteriosus, Dr. Gibson, 572
 Pneumonia in children, Dr. Variot, 464
 Ramsay, Dr., inflammation of the conjunctiva, 626
 Renon, Prof., right-sided pleurisy, 116
 Right-sided pleurisy, Prof. Renon, 116
 Rolleston, Dr., mitral stenosis, 414
 Routine examination of the feces, Dr. Herschell, 274
 Schuller, Prof., essential nephritic hemorrhage, 62
 Secretary neurosis of the stomach, Dr. Dargan, 220
 Steven, Dr., general cystic degeneration or transformation of the kidneys in the adult, 492
 Syphilitic pseudo-general paralysis, Dr. Bewley, 144
 Tropical abscess of the liver, Mr. Newbolt (illustrated), 518
 Variot, Dr., pneumonia in children, 464
 Whiting, Dr. A., hemiplegia, 194; clinical examination of the blood (illustrated), 680
 Certain injuries commonly associated with displacement of the head of the humerus, 696
 Clairret vierge, 482
 Clinical lectures, 1
 Clinical lectures for 1906, 10
 Clinical pathology, 327
 Cocainisation of the spinal cord, Mr. R. Jones, 683
 Coincident infection with diphtheria and typhoid fever, Dr. Nash, 121
 Coleman case, the, 591, 642
 Collagen frictions in panophthalmia, 563
 Collargol in ophthalmia neonatorum, 379; injections, 672
 Collier and barber, 201
 Colonial degrees and diplomas in Canada and Jamaica, 373
 Colonies for the feeble-minded, 135
 Company promoters, 89
 Compensation for trade anthrax, 515

 Universities and medical education, 533
 Vaccination, 318
 Work in later life, 666
 Wright's opsonic index established, 262, 289, 318
 Cost of small-pox, 52
 Cotton wool and swallowed foreign bodies, 599
 County Down asylum, 615
 Courvoisier's law, 672
 Council election at the R.C.S.Eng., 623
 Cremation, 410
 Crime, the treatment of, 354

Criminal lunatic, a, 299
 Orestes in dogs, 260
 Orier and wife v. Hope and Gurney, 293
 Crothers, Dr., responsibility of criminal inebriates, 64
 Crusade against consumption, 381, 383
 Crushed limbs, 343
 Curie, M., tragic fate of, 435
 Curious professional accidents, 490
 Curious slanders, 647
 Cysticercus, 131
 Cytorrhocytes lues, 322
 "Daily Mail" and advertisements, 270
 Danger of soothing syrups, 201
 Danger signal for the deaf, 435
 Darnell case, 481; defence fund, 513; presentation to, 665
 Death by misadventure, 377
 Death following scopolamine morphine injections, 27
 Death from ethyl-chloride, 264
 Death of a lunatic from choking, 15
 Deaths—end of each No.
 Deep injections of alcohol in neuralgia, 238
 Defective articulation, 20
 Delayed autopsy, 191
 Dental hospital for Ireland, 210
 "Detailing," 516
 Diabetes insipidus, 156
 Diabetes mellitus, 565
 Diagnosis of mediastinal tumours, 161
 Diagnosis of peritonitis after appendicitis, 21
 Dietary in diabetes and gout, Dr. Arany, 66
 Diabetic management of diabetes, 673
 Diabetic treatment of gastric ulcer, 230
 Differential diagnosis of tabes, Dr. Stewart, 421
 Differentiation of streptococci, 231
 Diocesan congress and faith-healing, 625
 Diphtheria, Dr. Wood, 606
 Diphtheria in Kent, 236
 Direct representative for Ireland, 85
 Direct representatives on the General Medical Council, 624
 Discipline in the royal infirmary, 589
 Discipline in teaching hospitals, 570
 Disjointed personality after influenza, Dr. Wilson, 224
 Distilled water a drug, 88, 107
 Distribution of Liege exhibition awards, 671
 Dividing Hungarian twins, 79

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXII.

WEDNESDAY, JANUARY 3, 1906.

No. 1.

NOTES AND COMMENTS.

Our Programme for 1906. Mr. GLADSTONE is reported to have said on a certain occasion, "I am a regular old Conservative. I never like change unless I know the reason." That, we venture to think, is the true spirit of progress. To-day a change has been made in THE MEDICAL PRESS AND CIRCULAR, and as it is a change dictated by reason, and we believe one in the direction of progress, we should like to place before our subscribers the motives by which it was dictated.

Our Past. But first of all let us examine what are and have been the features which have distinguished THE MEDICAL PRESS AND CIRCULAR from other organs of professional opinion. The chief of these is its brevity. While other journals have been vying with each other to produce a monster sixpennyworth, we of this journal have held on our way untempted to follow in their wake. If we were concerned with the management of a ladies' weekly or a review for idle people, we might be disposed to enter into this competition; but as it is our business to cater for a profession of busy men, we feel otherwise. It is not infrequently our lot when calling on our professional brothers to find piles of "monster sixpennyworths" lying in a corner of the consulting room clad in their original postal wrappers. We have marked the lesson of those piles, and we have remained fixed in our resolve to produce a journal that will be read.

Our Future. A journal that is to be read by medical men as a whole must be brief, pithy, and practical. The tendency of the medical journal of the day is to become more and more ponderous, like a work of reference, and less and less a sheet of news; and though we have nothing but admiration for the enterprise of our contemporaries and the results that they have achieved, we are convinced that our policy in medical journalism meets a distinct want. And this for the most practical reasons. The demand for THE MEDICAL PRESS AND CIRCULAR steadily increases every year, and advertisers also look to it more and more as a medium for making their wares known. With this tangible evidence before us we see every reason to develop our policy; none to change it. The

other claim that we make for our journal is that it is crisp, or, if we may use the expression, peptonised. Our work is to separate the husk from the wheat, to remove the shell from the nut, and to give our readers what we have to give in its most readily assimilable form. It is, we believe, to our having kept these objects steadily in view that we owe the fact that after nearly sixty-eight years of existence, far from showing any signs of senility, THE MEDICAL PRESS AND CIRCULAR takes a firmer grip on life every year.

Clinical Lectures. We have been seeking for some time past to develop our principles still further, and the changes which we make with the New Year are the result of much thought on the subject of the production of a useful, bright, and readable paper. Perhaps the most important innovation is that we propose to present each week a Clinical Lecture on a practical topic by a well-known teacher, in Great Britain or on the Continent. The clinical lecture has been growing in popularity as a medium for instruction, and we feel it will be a strong and acceptable feature if we bind ourselves to include one such lecture in each number of the journal. Arrangements are well in hand, and besides the lecture by Professor Mayo Robson which we give this week we have others by Sir Christopher Nixon, Professor Schüller, of Vienna, and Mr. R. C. B. Maunsell, F.R.C.S., ready for production in the succeeding numbers of January.

Abstracts of Practical Papers. Next we have determined to publish each week a carefully-selected abstract of important papers published in contemporary journals. We have secured the collaboration of an experienced staff for this purpose, and we propose to make it our object primarily to summarise those papers that have a direct practical bearing on the work of the practitioner, rather than those which have a nebulous scientific value that may or may not stand the test of time. Finally, a new arrangement of our columns and a fresh allocation of our space has been undertaken, so that proper prominence may be given to the several features, and a well-balanced whole result. What these arrangements are will be obvious to the readers of the present number.

Our old subscribers will find that though we have changed our dress we have in no wise changed our views, which we flatter ourselves are their views, on the purity of medical practice and the honour of medicine as a calling. We are bound to no section or segment of the profession; we serve no clique; we are entirely independent of outside influence or pressure. As such, we are free to speak our mind without let or hindrance, and we intend to continue to do so. What we believe to be right we shall continue to praise, and what we believe to be wrong we shall continue to denounce. Our motto still is, "Salus populi suprema lex," and in the belief that the health of the people is only attainable by a high standard of medical knowledge and medical conduct, we shall continue to use that motto as our touchstone. We trust that our journal in its rejuvenated form will do something to add to the happiness which we heartily wish all our readers in 1906.

LEADING ARTICLE.

THE MEDICAL MAN, ANNO DOMINI 1906

THE rapid evolution of scientific medicine presents us with an ever-shifting kaleidoscope of professional knowledge. The practitioner of to-day, no matter what his standing or his peculiar bent, must keep abreast of main advances, or in a few years he will find himself lagging hopelessly in the race. In so wide a field he cannot hope to know particularly more than one or two branches and to have a general acquaintance with the rest of the multitudinous subjects that fall within the range of modern medicine. Indeed, it seems almost hopeless for the general practitioner, burdened as he is with incessant calls upon his energy, to keep himself well-educated from the professional point of view. Even where post-graduate education is at hand, it requires no little determination to find the necessary time to attend classes and demonstrations. The medical diplomate or graduate is turned out from school or university a highly finished educational product, charged with a vast amount of information that will be simply an encumbrance to him when called upon to discharge the end and aim of his adopted career, namely, to comfort and heal the sick. There are several saving clauses, however, in the compact between general practice and medical science. The first is that while great, and in some cases enormous, strides have been made in the various branches of medical science and art, that of therapeutics has for the most part lagged behind with slow and halting steps. A lecturer will discourse eloquently upon the etiology, the pathology, the symptomatology and the diagnosis

of some condition, while the therapeutic aspect is disposed of in the last two or three minutes of his allotted hour. Yet treatment is the all-important thing for the future practitioner, not to mention the patient, an interested person of whom we are apt to lose sight at times in the excitement of our scientific ardour. Of what use is it to the medical attendant when sitting at the bedside of a sick person to ransack his mind as to Professor So-and-So's refinements and subtleties of diagnosis? Sick-room practice and laboratory research are for the most part poles asunder, and in the rough and ready tumble of general practice the advance has been made at a few points here and there rather than all along the line. So the general practitioner treats symptoms, trusts to a few approved remedies and throws advanced science to the winds—at any rate, until its advocates can furnish a convincing as well as a plausible case. In fact, he has been taught the lesson that much so-called knowledge is not really knowledge when tested in the crucible of experience. An amusing instance of misapplied high standard smartness recently occurred in a provincial centre of light and leading. A country surgeon sent a lad to the hospital of a neighbouring town for the purpose of having a deep-seated abscess opened. The patient was placed under the care of a Professor of world-wide fame, but he was sent back home without operation because an examination of his blood did not afford the evidence deemed necessary for the diagnosis of internal abscess. Thereupon the country surgeon called in a brother practitioner to give chloroform, and speedily relieved his long-suffering patient of his dangerous burden. The truth of this story, however much it may be suggestive of science run mad, is vouched for on the best authority. It illustrates one of the more disquieting sides of professional life nowadays, namely, the decay of skilled clinical observation, and the exaltation of laboratory methods that are in not a few cases complicated, fallacious, and technical to a degree. But from the mists of theory and of speculation now and then emerges the established fact or the reasoned conclusion which every educated medical man should know. This necessity has led to many attempts on the part of teachers, of authors, and of medical journals to fill the gap. So far as the MEDICAL PRESS AND CIRCULAR is concerned the re-casting of the form of the journal has been framed with that object clearly in view. By means of a careful abstract from the medical literature of all countries, it is hoped to supply readers with the solid information they require in a compact and readily assimilable form. The medical man of 1906 has an increasingly hard task to compass in his endeavour to keep up with the times. So far as lies in our power, we hope to furnish him with matter that he will find refreshing, stimulating, and nourishing, and in this way to proffer him a real assistance in what must ever be a laborious and self-sacrificing career.

The Bennett Testimonial Fund.

WE have been glad to learn that the movement among the old pupils of Mr. Edward H. Bennett, of Dublin, to commemorate in suitable form his services to surgery during his long professional career has received a widespread support. The committee charged with the execution of the wishes of the subscribers are now in a position to decide on the form the testimonial is to take, and we understand that it is intended to ask Mr. Bennett to give sittings for a portrait medallion, the original to be placed in the School of Physic in Ireland, and a copy in Sir Patrick Dun's Hospital. Medals are to be struck, of which a proof in gold is to be presented to Mr. Bennett, while a bronze medal is to be presented biennially to the winner of the Surgical Travelling Prize in Trinity College. Any funds remaining are to be invested, the interest being devoted to a prize to be presented to the candidate who obtains second place in the examination for the Surgical Travelling Prize. The decision of the Committee as to the disposal of the moneys subscribed will give universal satisfaction, as in no way could the memory of a great teacher be better perpetuated. We understand that any of Mr. Bennett's pupils, who, through inadvertence or other cause, have not yet subscribed can send their subscriptions to either of the honorary secretaries, Mr. H. R. Swanzy, 23, Merrion Square, or Mr. C. A. Ball, 12, Lower Mount Street, Dublin.

The Aliens Act.

THE Aliens Act passed last session comes into operation with the New Year, and it may therefore be presumed that the Home Office, under whose auspices its administration is to be carried out, have organised the necessary machinery for the purpose. As is usual with Government departments, when dealing with public health questions, no official place was given to a medical representative on the Committee that sat to advise the Home Secretary as to the necessary steps to be taken and regulations to be made under the Act, and consequently no medical officer has been appointed at head-quarters to supervise its administration. The three classes it is desired to exclude are the criminal, the pauper, and the diseased alien, and it is the last-named only that will provide real difficulty. The only country that has had much practical experience of the exclusion of undesirables is America, and the authorities there have discovered how difficult it is to construct a net whose meshes are sufficiently small to keep out all the rubbish. Each year in the States the medical tests become more stringent. The fact is that the aliens become as experienced as the medical inspectors, and they evolve all sorts of counter-weapons with which to fight their examiners. For instance, they know the astringent powers of adrenalin, and insert it into their eyes to mask the congestion produced by granular lids. The diseased alien is a serious menace to the public health of the low quarters of shipping and indus-

trial towns, and if the Act is not to become a by-word and a farce its administration must be carefully watched.

Sanitary Zeal.

THE tests which the Sanitary Institute applies to would-be inspectors do not apparently include one to prove the sense of humour possessed by candidates. At least so one would judge from an incident that occurred in the Harrow Road last week. A sanitary inspector of the Paddington Borough Council espied in passing the headquarters of the Paddington Liberal Association, a string of German sausages, labelled "Sevenpence half a pound." Here was a clear case of violation of the Horseflesh Act, 1889, which provides that in places where horseflesh is sold, the fact must be indicated over the door of the shop in letters not less than four inches deep. The inspector stepped inside, interviewed the secretary (whose name aptly enough is Mr. W. Jacobs), and complained of the infringement of the law. The secretary was obstinate. He explained that the sausages were not articles for sale, but munitions of war wherewith to fight the coming election, not—as the inspector might suppose—in the same way that sausages are used on the pantomime policeman, but as an object lesson of the future diet of the "rude mechanical" if the tariff-reform candidate got in. But the inspector was not to be fobbed off with such transparent excuses, and a summons was served in due course. Fortunately the case came before the right man—Mr. Plowden, and the inspector departed with a flea in his ear for his stupidity. When sanitary zeal doth outrun discretion it cuts a poor figure indeed.

A Thirty-Three Hours' Day for Carmen.

To secure an eight hours day is the dream of many labour reformers. There are some occupations, however, such as those of railway-men, pilots, fishermen, dairymen, publicans, market gardeners, printers, carmen, cab-drivers, and so on that by reason of their essential nature it would be difficult to subject to an arbitrary time-limit. On the other hand it seems clear that the State should intervene at some given point in the interests both of workmen and of the community. A great element of public danger is introduced when the hours of labour are stretched to an unreasonable length, as witness the familiar railway smash due to the lapse of a signalman who has been on continuous duty for twenty or thirty hours or more. Last week a carman was brought before a London magistrate on a charge of being drunk. He pleaded that he had been in the employment of the same firm for over thirty years, that he had never before been charged with drunkenness, that he had been on duty for thirty-three hours continuously, and that for the past eleven weeks he had never been in bed. Under these circumstances the magistrate very justly refused to fine him, and communicated

with the employer. If Parliament cannot guarantee an eight hours day, it can make anything beyond a twelve hours day illegal. The carman's drunkenness in the above case was not improbably the outcome of a physiological attempt to stimulate a brain exhausted by prolonged insomnia. Anyway, a social matter of this kind deserves the careful consideration of our legislators.

A Chemist's Fatal Error.

LAST week an inquest was held at Sheffield upon the body of a Harrogate lady visitor who died after taking a dose of physic made up by a local chemist. It was found that in dispensing the medicine, the unfortunate chemist, owing to a mistake in the label on one of the bottles, had substituted a solution of nitrate of mercury. The explanation given was that during the removal of the business on a wet day the label was rubbed off, and that in some way or other the label was replaced on the wrong bottle. Such a state of matters is hardly satisfactory, however, inasmuch as a drug of the deadly kind in question should have a permanent label indelibly affixed to the bottle. Indeed, so far as that goes, every stock bottle on a chemist's shelves should obviously be labelled in such a way as to withstand the wear and tear clearly inseparable from the business of dispensing. Then, again, there is no particular reason why chemists should not keep their poisons in distinctive bottles and locked away in special cupboards. That something of the kind is imperatively needed is shown by the occurrence from time to time of such tragedies as that recorded last week at Sheffield. It is by no means clear that chemists have hitherto taken all the precautions necessary to reduce the margin of poisoning accidents to its unavoidable minimum.

What is a Successful Operation?

It often happens that in the newspaper account of some heroic surgical procedure that has ended in the death of the patient it is stated that the operation was perfectly successful. The situation thus displayed tickles the humour of the public, and every medical man must have had the problem laid before him scores of times by intelligent patients. The answer lies in the ultimate meaning attached to the word "successful." If the term be limited to the restoration of life or limb by surgical intervention, then the untimely death of the person operated upon within a few hours or days would indicate the use of its opposite—"unsuccessful" as the proper epithet. The surgeon is naturally eager to escape the stigma of non-success, and has accordingly adopted the plan of claiming a successful result so far as his operation has been concerned, while death is attributed to contributory unavoidable causes. This subtle distinction is readily accepted by coroners' courts and by journalists, who as a rule fully recognise the necessity of protecting the reputation of the conscientious and responsible

men engaged in the practice of modern operative surgery, which, unhappily, has not yet been reduced to the position of an exact science. Any surgeon who reckoned as "recoveries" or "successes" cases in which post-operative death followed at a short interval would infallibly lay himself open to the charge of "cooking" his statistics.

"Signed by Fifteen Eminent Medical Men."

It is a well recognised fact that in infancy and childhood, and throughout the growing stages more sleep is needed than in adult life. Starting on this obvious ground, a manifesto has been drawn up in the form of a letter "signed by fifteen eminent medical men" and published in a London newspaper. It points out the danger that under modern methods school children are often unable to get sufficient sleep, to the consequent damage of the brain and the danger of a nervous breakdown in after life. So far as the matter of this manifesto is concerned there can be little doubt that it falls within the legitimate sphere of the medical profession to educate the public upon a subject so vital to the welfare of future generations. But why append the names of the "fifteen eminent medical men"? It is either ethically right or ethically wrong to send a signed communication to a public newspaper, dealing with a professional subject. Of late years Presidents, and would-be presidents of Royal Colleges—not to mention shoals of smaller fry—have not hesitated to send signed letters upon all sorts of medical topics to lay editors. Possibly medical opinion is undergoing a revolution upon this, as upon many other points. Again, the idea seems to prevail in some quarters that two or three men may sign their names with impunity where it would be wrong for one to do so. By a simple extension of this curious principle any possible ethical offence might be thereby diluted to any required degree. Fifty names, for instance, would be calculated to silence the most captious layman, if only by hopelessly confusing him as to the identity of individual signatures.

Red Light and Scarletina.

THERE is little understood up to the present of the influences of light upon the chemistry of the body, and any facts which we know are purely empirical. It is right and natural, therefore, that those who believe strongly in the therapeutic action of red light in small-pox should test actinic therapy in the case of other acute exanthemata. It is in this attitude of mind that Croff of Nürnberg has studied the influence of red light on the course of scarlet fever, and it may be admitted that his results are encouraging. His method was to exclude white light and to admit only a limited amount of red light. In his opinion this treatment brought about an early disappearance of the rash, as well as a rapid return to normal temperature. Instead of the seven or eight days usually required to get rid

of the fever, Croff found that temperature came down, sometimes by crises, on the third or fourth day. The treatment had to be strictly maintained, as even a few minutes' exposure to daylight was in some cases sufficient to cause a recrudescence of the rash. On the complications of the disease the treatment had no effect.

Libraries and Infectious Disease.

THE prevention of communicable diseases unquestionably forms one of the great aims of sanitary science. In many directions, however, its achievements fall hopelessly short of its ideals. There are many rocks ahead, not less in the inherent character of the various zymotics than in the complex environment of modern life. Library books have always provided sanitarians with a hard nut to crack. Reading is a great solace and recreation to the sick, so that a certain proportion of library books are bound to get into the hands of persons suffering from some form or other of infectious malady. From the circumstances of the case it is impossible for the library authorities to be aware of the facts, and were it possible the books would have to be destroyed, for it is hardly practicable to subject bound volumes to any efficient process of disinfection without rendering them useless for library purposes. The remedy against the spread of infection by this particular agency is not easy to discover. While human nature is constituted on present lines, it is likely that library books will continue to find their way to fever-stricken bedrooms. Perhaps the simplest way out of the difficulty would be to make a general appeal to medical men to instruct their patients as to the risks incurred by selfish exposures of the kind. Another practical step would be to place libraries in close touch with public sanitary departments, so that the whereabouts of every notified infectious case might be kept in full view of the library officials. Lastly, an offence of the kind might be made punishable by fine.

PERSONAL.

THE Prince of Wales has opened a native Medical School at Lucknow.

THE Princess of Wales has sent a Christmas present of toys from her Royal Highness' children and the children of Kew to the little patients in the London Hospital.

SIR DONALD CURRIE's conditional offer of £20,000 to Belfast Queen's College has resulted in a net sum of no less than £70,000 for that fortunate body.

SIR ROBERT FINLAY, K.C., who has a medical qualification, is a Parliamentary candidate at the forthcoming election.

A PRIZE of £100 and a silver cup offered by Mr. Edgar Speyer for the best essay on the economical management of an efficient voluntary hospital has been awarded to Mr. Godfrey H. Hamilton, secretary of the National Hospital for the Paralysed and Epileptic, London.

DR. MARK ANTONY MACDONNELL, M.P., brother of Sir Antony MacDonnell, formerly in practice in Harley

Street, will not contest the Leix Division of Queen's County at the next election.

SIR HENRY BURDETT, it is stated, will contest North Paddington as an Independent Unionist.

THE name of Dr. F. W. Suberton has been placed upon the Commission of the Peace for the City of Manchester.

DR. J. W. BEATTIE was recently presented in the Mayor's Parlour, Town Hall, Sunderland, with a gold watch, bearing the following inscription:—"Presented to J. Walker Beattie (with a cheque for £200) as some recognition of 25 years' work in Sunderland, freely given in the cause of humanity, December 21, 1905."

PROFESSOR KOCH is about to take charge of an expedition to investigate sleeping sickness in German East Africa. He will co-operate with the expedition sent out by the Liverpool School of Tropical Medicine, and is expected to remain in the district about eighteen months.

SIR HALLIDAY MACARTNEY, who is about to retire from the responsible post of English Secretary to the Chinese Legation in London, was educated for the medical profession in Edinburgh University, and served in the Army Medical Department from 1858 to 1862, when he saw much active service in China.

MR. J. F. OBREE, J.P., a well-known Southampton shipbroker, has recently been restored to health after a serious illness, and as a thank offering, has intimated his intention of dividing the sum of £2,850 among the hospitals and charitable institutions of the town.

AT a recent meeting of the board of the Selby Cottage Hospital on Saturday, Miss Standerling, of Selby, expressed her wish, through Dr. Todd, the medical officer, to defray the cost of building a surgical ward for women and an operating-room for the hospital. Miss Standerling also proposed to give £2,000 towards the endowment of the institution.

SIR HENRY LITTLEJOHN has resigned the chair of Forensic Medicine, which he has held for the past eight years. The main part of his professional career has been identified with the Royal College of Surgeons of Edinburgh. He is now in his 78th year, and still gets through a great amount of hard work.

MRS. ADA LEWIS HILL, widow of the late Samuel Lewis, has forwarded for the year 1905 her annual gift of £10,000 to King Edward's Hospital Fund.

THE Hon. Stephen Coleridge has telegraphed the Lord Mayor of London to impound all tickets presented at the door of the recent Hospital Sunday meeting until he has obtained legal advice as to future action.

IN a recent issue we announced that Mr. Edgar Speyer had presented the magnificent sum of £100,000 for the benefit of certain medical charities. The securities to the value of this amount he placed in the hands of Mr. E. J. Bawden, who has now completed the terms of the Trust Fund, Lord Hillingdon, Lord Revelstoke, and Mr. Bawden being the trustees.

MRS. UMFREVILLE PICKERING has generously given one thousand guineas to the West London Hospital, through Dr. D. W. C. Hood, C.V.O. (as a steward of the festival dinner now being organised), for the purpose of endowing and naming one of the beds in perpetuity.

DR. R. R. RENTOUL, author of "Proposed Sterilization of Certain Degenerates," has been asked to give evidence on January 19th before the Royal Commission on the Care and Control of the feeble-minded.

A CLINICAL LECTURE

ON

THE DIAGNOSIS AND TREATMENT OF CANCER OF THE STOMACH.

BY

A. W. MAYO ROBSON, F.R.C.S.

Hunterian Professor in the Royal College of Surgeons of England.

CANCER in itself has no definite symptomatology, and the later symptoms of gastric cancer depend almost entirely on the site of the disease.

If the body of the stomach is the starting point, all localising symptoms may be entirely absent until the loss of strength and wasting compel the patient to seek advice, when a tumour can often be felt.

If the growth invades the pylorus, it tends before long to interfere with the escape of the stomach contents, and so to give rise to retention of food products, to dilatation and to visible peristalsis, associated with pain, and when the obstruction is becoming more complete it leads to vomiting with rapid emaciation. When the growth is at or near the cardiac orifice a difficulty is experienced in the entry of food into the stomach, giving rise to a suspicion of œsophageal obstruction. Wasting is often a marked symptom before pain directs attention to the affected part, though pain is usually present at an early stage.

It will thus be seen that at the outset, in nearly all cases of gastric cancer before the orifices have been interfered with there may be no local symptoms to draw attention to the stomach as the seat of the disease. It has therefore not infrequently happened that a patient has died from another illness and at the autopsy an unsuspected gastric carcinoma has been found.

This early condition is the important stage of the disease from the point of view of radical treatment, for at this time the cancer is localised, and if it can be widely removed either cure or long continued relief may be looked for in a large proportion of cases.

In order that the best results may be attained, the physician and surgeon must act in concert, so that by a timely diagnosis an operation may be undertaken at the earliest possible date. There is ample evidence to show that for some length of time the cancer is a purely local disease; and, just as in the breast, the tongue, and the uterus, we can point to patients living comfortable and happy lives years after the removal of the disease, so in gastric cancer it is reasonable to assume, and in fact can now be proved by positive evidence, that a like result may be hoped for. Here, however, we are faced with the difficulty of a sufficiently early diagnosis being made, and it is not only necessary for us to appeal for an early, exhaustive, and persistent investigation into suspicious stomach cases, but that when the suspicions are becoming confirmed an early surgical consultation may be held and, if needful, an exploratory operation carried out to complete the diagnosis. Whenever a patient at or after middle age complains somewhat suddenly of indefinite gastric uneasiness, pain and vomiting, followed by progressive loss of weight and energy and associated with anæmia, the possibility of cancer in the stomach should be recognised, and in a suspected case, if no improvement takes place in a few weeks at most, an exploratory operation is more than justified. As Professor Osler says, the important aid of an exploratory operation should be more frequently advised.

Diagnosis.

Although cancer of the stomach may occur in early life, yet it usually comes on at or after middle age, from 40 to 60 being the most frequent age. I have operated for cancer of the pylorus at 21 and for cancer of the bowel at 14. Men are more frequently affected than women. Osler observed 126 in men to 24 in women. In the Leeds Infirmary the proportion was for ten years 36 males to 23 females. The usual clinical manifestations are loss of appetite and wasting with loss of strength coming on in a patient otherwise well, and with nothing to account for

the dyspepsia. Two features are prominent—acuteness of course and abruptness of onset. Perhaps the friends first notice the change in the patient, who, from being active and well, becomes tired, listless and anæmic, without any symptom pointing to the stomach. Or the first symptom may be pain after food or flatulent distension and great discomfort, leading to limitation of the intake so as to save after effects. Vomiting may be entirely absent, and is frequently not seen until the outlet of the stomach is becoming narrowed or the cavity encroached on. If early, the vomit consists of food with mucus, later of altered blood in the shape of coffee-ground material, and at times, though more rarely than in ulcer, of pure blood. Loss of flesh is well-marked, and may be the only symptom beyond loss of appetite and discomfort after food. Even loss of appetite may be absent at the beginning when loss of weight is already showing itself.

Pain is usually felt at the epigastrium, but, unlike ulcer, there is generally an absence of tenderness on pressure, until the peritoneal coat becomes involved, when local peritonitis may give rise to tenderness.

Professor Osler's analysis of symptoms at onset gives pain as present in 48, dyspepsia in 46, vomiting in 21, of which 2 were vomiting of blood; anorexia in 4, dysphagia in 3, tumour in 1, jaundice in 1, while in 13 there were no symptoms at the outset.

The three most constant symptoms are pain, vomiting, and tumour.

In 86.6 per cent. pain is present.

In 85.3 per cent. vomiting is present.

In 76.6 per cent. tumour is present.

The pain varies from slight attacks to constant, severe, and disabling distress. It may be made worse by food or it may be continuous and not much influenced by diet. My experience is that the nearer the pylorus the more severe the pain, this being apparently due to obstructed outlet and in some cases to painful peristalsis. On several occasions I have found tumour to be the first evidence of the disease.

An examination of the stomach contents obtained after a test meal should not be neglected. While free HCl in good quantity is against a diagnosis of cancer, the absence of free HCl is decidedly in favour of it, as in 80 to 90 per cent. of cases of cancer of the stomach free HCl is absent, or if present is in very small quantity. An excess of free HCl is decidedly in favour of ulcer, just as the presence of lactic acid is of cancer. A microscopic examination of the stomach contents may show blood cells and portions of growth which are of course of the greatest importance, as though blood may be present in case of gastric ulcer, portions of growth and cancer cells are absolutely pathognomonic of cancer.

I would not advise under any circumstances forcible lavage and curettage as recommended by some authorities, in order to obtain material for microscopic examination.

The presence of the Oppler-Boas bacillus has been given importance by some authors, who speak of its being present in 90 per cent. of all cases of gastric cancer.

In many cases—Fenwick says in one-third—a rise of temperature at some period will be found, but in the greater number of cases there is a low or even a sub-normal temperature.

Anæmia, resembling in appearance the pernicious form, is a striking feature of gastric cancer; it is dependent on absorption from the diseased stomach, and from the growth, leading to blood destruction, and on the loss of blood from repeated small hæmorrhages into the stomach.

Laache states that there is a notable diminution in the number of red corpuscles present in the blood. Fenwick says that the corpuscular richness seldom increases under treatment; but at the same time, the number of red cells rarely falls below 1,500,000 per cubic millimetre. The former peculiarity serves to distinguish the disease from many other forms of secondary anæmia, and the latter from the pernicious form, where, according to Henry, the cells always number less than 1,000,000 per cubic millimetre before death occurs. Leucocytosis usually occurs, especially if there is perigastritis or pyrexia, but its diagnostic importance is not great. Tedeschi (*Gaz. degli Osped.*, Jan. 23rd, 1905) states that in cancer of the stomach blood can always be found in the motions on adopting the Guaiacum test.

As an element of prognosis, Fenwick lays stress on the total disappearance from the saliva of potassium sulphocyanide. He says that he has never known a patient to live more than a month after the observance of the phenomenon. Cammidge lays stress on the diminished excretion of chlorides in the urine in cancer, which may afford a help in the diagnosis.

Rommelaere believes that the elimination of less than 180 gr. of urea per diem, by a patient who suffers from chronic indigestion is pathognomonic of cancer, but this is probably, though suspicious, not absolutely true; though it may be permissible to assume that where 450 gr. of urea are excreted, carcinoma does not exist. The presence of ascites and of œdema of the feet are seen in cases too advanced to merit consideration from a purely surgical point of view.

Physical Examination of the Patient.

Where the cardiac end of the stomach is involved, there may be difficulty in deglutition, and in such cases a bougie may be arrested at the entrance to the stomach.

A palpable tumour is discoverable in from 70 to 80 per cent. of all cases of cancer of the stomach.

Inspection of the abdomen may show a perceptible tumour in the epigastrium, or in the left or right hypochondrium, and if the patient is thin it is often easy to manipulate the tumour and to ascertain its relation to the rest of the stomach and to neighbouring organs, especially as the recti are usually free from rigidity, a condition which is quite different in chronic ulcer. It is usually hard, nodular, and irregular, and often free from tenderness, except when peristalsis occurs, or where there is perigastritis. Peristalsis from left to right can often be seen when the tumour is at or near the pylorus, and on palpation the organ is felt to harden under the hand.

The tumour may be very movable, and may be capable of displacement down into the pelvis and upward under cover of the ribs; this from a surgical point of view being, of course, very favourable. Tumour of the pylorus due to chronic ulcer is generally fixed under cover of the liver, and cannot, as a rule, be well defined, especially if, as often is the case, the right rectus is rigid and resists pressure. Retraction and fixation of the navel is an important sign of advanced disease, the growth having involved the round ligament or the subperitoneal tissue near the umbilicus. Ascites, as shown by a thrill on flicking the abdomen in the flanks with the finger-nail, and as evidenced by other well-known signs, is a very unfavourable symptom, as showing the disease is very advanced and probably diffuse.

The position of the growth in the stomach may be shown, as also the shape of the stomach, either by inflating the stomach through a tube or by giving the patient a teaspoonful of sodium carbonate dissolved in water; if there is free acid in the stomach, it will decompose the sodium carbonate, and CO₂ will be evolved, but if there is no free acid in the stomach, about 30 grains of tartaric acid dissolved in water can be given and this will immediately cause the stomach to be distended and its outline and relation to the tumour will be made manifest. In cases of ulcer, the sodium carbonate dose alone is often sufficient; but in cancer the absence of free acid usually necessitates

the tartaric acid dose also, thus affording some help in diagnosis. The presence of enlarged veins on the surface of the abdomen (indicating obstruction of the venous return) of enlarged glands in the groin, of nodules on the skin, of enlarged glands over the left clavicle (indicating diaphragmatic extension) or of other secondary signs of growth in the liver, bowels or peritoneum must all be taken into account in considering the case from a surgical standpoint.

Enlargement of the glands above the left clavicle in my experience occurs in from 5 to 10 per cent. of all cases of cancer of the stomach; the gland between the roots of the left sterno-mastoid, as well as glands behind that muscle, may be involved, and as pointed out by Dr. Newton Pitt may sometimes be more readily felt by making the patient cough.

For the surgeon to be able to perform his best work, the disease should be recognised before a tumour is perceptible, though as can readily be shown, very successful operations may exceptionally be undertaken even when the tumour is visible through the abdominal wall.

Of the tumours of the stomach that can be palpated—some of which may be visible—according to Fenwick, 81 per cent. are situated in the body of the organ, 71 per cent. at the pylorus, and only 55 per cent. at the cardiac end or fundus.

Nearly all tumours of the stomach move downwards on deep inspiration.

The size and shape of the tumour may vary considerably, and the position, though usually above the umbilicus, may in pyloric growth be in the hypogastrium though I have seen and operated on a cancer of the pylorus that formed a tumour in the left hypochondrium and which on expiration disappeared under the left costal margin.

A small tumour of the pylorus, barely perceptible to palpation, may lead to enormous dilatation of the stomach, and in nearly all cases of cancer of the pylorus a stomach splash may be elicited.

When the disease involves the middle of the stomach an hour-glass shape results, and the proximal cavity as a rule becomes considerably dilated.

Treatment.

This may be considered under two heads—medical and surgical. Medical treatment cannot cure, and can do very little even to prolong life; it therefore applies only to cases too advanced for surgical treatment or where operation is declined. It aims at nourishing the patient as much as possible, and at relieving pain or other symptoms as they arise.

Surgical treatment offers the only chance of real relief, and the only possible chance of cure.

Having made the diagnosis, if necessary by an exploratory operation, it will be generally advisable to have everything ready to follow up the exploratory procedure by whatever further operation may be called for. It may be discovered that the disease is manifestly not malignant and that some curative operation can be done, as in a number of cases in which I have found ulcers surrounded by inflammatory thickening in which I was able either to excise the ulcer or to perform a gastro-enterostomy and thus to cure the patient.

Or it may be discovered that the disease resembles malignancy both in its history and physical signs and in the form of the tumour, and is yet, if we may judge from results, apparently not malignant, as in a number of cases under my care, which were at the time of operation supposed to be suffering from cancer of the stomach and in which, as the disease appeared to be beyond removal, a gastro-enterostomy was performed in order to short-circuit the obstruction and so to give relief, but which patients, as the result of surgical treatment, are now not simply relieved, but apparently quite well.

Now, I would lay particular stress on this class of cases, for I think it serves to explain some misconception about cancer generally. It would be easy for anyone, looking at the subject from a one-sided point of view, to raise a claim to having cured a number of

cases of cancer of the stomach by gastro-enterostomy; but I do not for one moment believe that any of these cases were more than inflammatory tumours formed around chronic gastric ulcers; nevertheless I have no doubt that they would have proved fatal, just as certainly as if they had been cancer, had no operation been done. This brings me to another interesting point, and that is the alleged increase of cancer; for I feel sure that many cases like those related above would have been certified as deaths from cancer of the stomach had no operation been done or, in case of death, no necropsy or microscopic investigation made, and I think we must take such cases into account before hastily deciding that this disease is on the increase.

The cases also illustrate another point, and that is, even though a tumour be present, and even though it be probably too large for removal, it may be quite worth while advocating an exploration, to be followed up by gastro-enterostomy if that be practicable, in the hope that the disease may prove to be wholly or partially inflammatory, which the physiological rest secured by gastro-enterostomy will either cure or materially relieve.

Now, to pass to the genuine cancer cases, what can we do for them when diagnosed at an early stage? This will depend (1) on the position of the growth; (2) on its extent; (3) on the presence of adhesions; and (4) on glandular invasion or secondary growths.

First, as to position. In irremovable growths at the cardiac end, if it involve the cardiac orifice and adjacent portion of the stomach, gastrostomy should be performed in order that starvation may be staved off. The view that gastrostomy is both a dangerous and useless operation is, I know, held by some surgeons as well as physicians, but I feel convinced that such views are mistaken ones. When these cases, either of cancer of the cardiac end of the stomach or of the oesophagus, were handed over to the surgeon in a moribund condition the mortality of gastrostomy was, of course, terrible, and the short survival, even if successful from an operative point of view, made the surgical treatment useless; but when I myself can point to a series of gastrostomies performed since 1897 not only without any mortality, but with comfort to all and great prolongation of life to some, I feel that I have good grounds for saying that the operation is well worth doing. In several cases the patients have lived a year or more, have gained considerably in weight, even up to 2½ st., and have lost their pain and the distressing sense of starvation.

The next class of cases is that in which the disease involves a great part or the whole of the stomach, the disease being irremovable and gastro-enterostomy impracticable, and in which any attempt at taking food brings on pain and vomiting, so that the patient must rapidly die in great distress if not relieved; here a jejunostomy can be performed by a very simple and similar procedure to that of gastrostomy, and through a Jacques catheter sufficient food can be given to ward off starvation and relieve the pain caused by attempts at taking food by the mouth. This operation can be done through the small exploratory incision, and need involve very little longer time. It may prolong life for months and make the end much easier and certainly less painful. I reported a case of jejunostomy in 1891 in which the patient lived three months. On November 4th, 1904, I read a paper before the Royal Medical and Chirurgical Society on a new method of performing the operation and gave the notes of a case in which the patient lived for a year after jejunostomy. Although the operation is rarely called for, it is one, nevertheless, which should be borne in mind, as in appropriate cases it may confer a great boon upon the patient and render tolerable an otherwise comfortless existence.

The third class of cases to be considered is where the disease involves the pylorus and is producing obstruction to the passage onwards of the gastric contents, but where, on account of the extreme feebleness of the patient or because of extensive adhesions, secondary

growths or involvement of glands, it is considered unwise to attempt pylorotomy, or partial gastrectomy, though there is sufficient free stomach wall left to enable a gastro-enterostomy to be performed. In such cases a gastro-enterostomy, if performed with proper expedition and adequate precautions, affords the greatest relief to the sufferer, who not only loses the distress due to painful peristalsis and to the irritation of retained secretion, but also becomes freed from the toxæmia due to absorption of the poisonous fermenting stomach contents, which are drained away into the intestine and there disposed of. Thus life is prolonged and made more comfortable, flesh and colour are regained, and even in cases of cancer the patient may have a new lease of life; moreover in some cases where the condition of the patient and not simply the extent of the growth has prevented a radical operation the speedy restoration to health enables a radical operation to be subsequently undertaken. The following cases serve to illustrate what I mean:—

CASE 1.—Mr. B., æt. 62. Symptoms for a year. Epigastric tumour noticed for a month. No free HCl in vomit. Exploratory operation, November 13th, 1900. Ring of cancer found, forming hour-glass shaped stomach. Patient too ill for gastrectomy; posterior gastro-enterostomy performed. Good recovery. December 20th, a month later, partial gastrectomy performed, the ring of growth being removed, and the cut ends of the stomach being fixed together over a large bone bobbin. Good recovery, returned home within the month. Quite well a year later. Letter, Nov., 1902, to say that Mr. B., had put on flesh, gained colour, and been able to take food well for over a year, but had succumbed to exhaustion from secondary growths in the omentum, March 30th, 1902, about eighteen months after operation.

CASE 2.—Miss B., æt. 24. Five years' history of stomach symptoms with great loss of flesh and recently coffee-ground vomit with tumour at epigastrium. Exploratory operation April 17th, 1902. Large tumour found involving the pylorus and anterior wall of stomach. Enlarged glands rendered gastrectomy inadvisable. Posterior gastro-enterostomy performed. Good recovery and returned home on the nineteenth day. Seven months later Dr. — wrote to say that patient, who weighed 4st. 5lb. at the time of operation, on September 1st weighed 8st. 1½lb., thus nearly doubling her weight in five months, but that she had recently developed jaundice, possibly due to extension of the growth to the common bile duct.

CASE 3.—Mr. B., æt. 36, seen with manifest tumour of the stomach, October 26th, 1901, and with a history of stomach trouble extending over several years, with vomiting of blood and passage of mæna on two occasions within the preceding four months. At the operation a large tumour involving the duodenum and pyloric end of the stomach, too adherent for removal, was found and gastro-enterostomy performed. After the operation he went abroad and for six months he rapidly gained weight and felt very well. He then began to get thinner and lose strength, and without any pain he gradually lost strength and succumbed in September, 1902, eleven months after operation.

CASE 4.—The patient was a married woman, æt. 37. Cancer of the body of the stomach and pylorus with dilatation was diagnosed. Gastro-enterostomy was performed on December 21st, 1899. She made a good recovery, and was so well that gastrectomy was advised, but cancer of the uterus supervened, and prevented further operation. She lived for nine months in comfort and was able to take ordinary food.

CASE 5.—The patient, a man, æt. 63 years, had symptoms for five years, at first those of chronic ulcer, with tumour associated with hæmatemesis. Gastro-enterostomy was performed on March 22nd, 1901. He made a good recovery and returned home at the end of the month, having gained 4lbs. in weight during the fourth week. He ultimately gained about 2st., and lived for a time in great comfort, but the growth progressed and he succumbed to exhaustion

about a year later, having been able to enjoy life for some months.

CASE 6.—Mr. W., æt. 68, operated on July 18th, 1902, for pyloric tumour with dilatation of the stomach, the patient being extremely feeble, and suffering great pain. The disease appeared to be cancer and the glands were extensively involved, so that gastro-entrostomy only could be performed. A letter a year later from Dr. — says the patient gained 10lbs. up to November and is now 14lbs. heavier than before he fell ill last June. He is able to take regular exercise and has never felt any pain after taking any meals whatever since the operation. He was well three years later.

Other cases could be given, but these will suffice to show the beneficial effects of gastro-entrostomy even in advanced cases of cancer of the stomach, for, as will be seen immediately, it is only in the cases too advanced for removal that the short-circuiting operation should be performed.

The operation can be done with little risk, for including all my cases of posterior gastro-entrostomy for cancer, the mortality is under 5 per cent., a great contrast to the death rate of these cases a few years ago, when only the anterior operation was a rule performed.

The remaining class of cases is of great interest and includes those where the disease is limited to the stomach, and where the lymphatic glands and adjoining organs have not been seriously invaded, the patient being in a sufficiently good condition to permit of the radical operation being done.

At first sight it would appear hopeless to expect that eradication of the disease could be performed in an organ situated as the stomach is, and so freely supplied with blood vessels and lymphatics, yet a careful study of its anatomy shows it to be fixed only at the cardiac extremity, and with the exception of that part the remainder is as freely accessible for operative purposes as are the intestines; moreover the disease, if caught, early, can be as completely removed as cancer of the colon. The following are examples:—

CASE 7.—Mrs. J., æt. 30. Symptoms five months, tumour noticed three weeks. Operation January 1st, 1901. Tumour found, involving the whole circumference of the pyloric end of the stomach, a short distance from the pylorus. After the growth had been widely excised, the distal and proximal ends of the stomach were brought together over a large bone bobbin. Glands were excised from the lesser and also from the greater omentum. Smooth recovery. The patient enjoyed good health for over four years before there were any signs of recurrence of disease in the abdomen.

CASE 8.—Mrs. S., æt. 54. Loss of flesh, and pain, with failing health for eight months; slight jaundice and tumour in epigastrium and right hypochondrium for a shorter period. Operation August 8th, 1900. The gall bladder, containing gall stones and the site of tumour, was removed. As the adjoining portion of the liver was involved, a wedge-shaped partial hepatectomy was performed, and as the pylorus was also involved in the growth a partial gastrectomy including the pylorus was done, the cut section of stomach being united to the duodenum by two continuous sutures over a bone bobbin. The removed tumour examined microscopically after operation proved to be cancer. That part of the abdominal wall to which the tumour had been adherent was also excised. The patient was in good health five years later.

CASE 9.—Mr. A., middle-aged, who had been ailing for a year and had had stomach symptoms for three months and a noticeable tumour for six weeks, was supposed to be too ill and anæmic for operation, but as the tumour, which was situated in the left hypochondrium and epigastrium was freely movable, I decided to operate. On May 23rd, 1900, I found a mass of cancer involving the centre of the stomach, which I removed along with some glands adjoining it. Recovery was uninterrupted. The patient was in good health over two years later.

CASE 10.—In the *British Medical Journal* for November 8th, 1902, I reported a case in *extenso* where I

had removed the whole of the stomach, except a small portion of the dome adjoining the œsophagus, for malignant disease, on March 18th, 1901. I am glad to say that this patient, nearly five years later, remains in absolutely good health; he has a good appetite, enjoys his food, and is able to attend to his business, as usual. These cases will be sufficient to show that removal of even a considerable portion of the stomach may be something more than a palliative operation, and I think it justifies me in saying that although it is better to have cases of cancer diagnosed and operated on early, yet we need not take the pessimistic view which has been given by some surgeons that if a tumour be manifest it is too late to perform a radical operation.

I hope I have advanced sufficient evidence to prove:

1.—How desirable it is to make an early diagnosis of cancer of the stomach in order that a radical operation may be performed at the earliest possible moment.

2.—That it may be needful to perform an exploratory operation in order to complete or confirm the diagnosis.

3.—That such an exploration may be done with little or no risk in the early stages of the disease.

4.—That even where the disease is more advanced and a tumour perceptible, an exploratory operation is as a rule still advisable in order to carry out radical or palliative treatment.

5.—That where the disease is too extensive for any radical operation to be done the palliative operation of gastro-entrostomy, which can be done with very small risk, may considerably prolong life and make the remainder of it much more comfortable and happy.

6.—That some cases, thought at the time to be cancer, too extensive for removal, may, after gastro-entrostomy, clear up completely and get quite well.

7.—That in cases of disease of the cardiac end of the stomach too extensive for removal, the operation of gastrotomy may considerably prolong life and prove of great comfort to the patient by preventing death from starvation.

8.—That even where the disease is too extensive for removal or even for a gastro-entrostomy being performed with a fair chance of success, the operation of jejunostomy may occasionally prove of service to the patient.

9.—That where a radical operation can be performed the thorough removal of the disease may bring about as much relief to the patient as does the operation for the removal of cancer of the breast, uterus and other organs of the body, and that in some cases a complete cure may follow. Prevention is, however, better than cure, and certainly much better than mere relief. I think, therefore, the fact should not be lost sight of that cancer is predisposed to by chronic ulcer, and in no less than 59.3 per cent. of the cases of cancer of the stomach on which I have operated the history had pointed to antecedent ulcer.

The origin of carcinoma in an ulcer of the stomach is only another instance, added to many of which we have knowledge, of the effect of persisting irritation in establishing malignant disease. Carcinoma occurs most frequently in those areas in which the ulcers chiefly lie. Whatever the frequency of the malignant change in chronic ulcer may prove to be, the fact of its occurrence should be an additional incentive to the earlier surgical treatment of ulcers which prove rebellious. I firmly believe that greater regard for oral asepsis and more careful attention to the teeth would save much stomach disease, and I think one of the chief causes of the frequency of gastric ulcers among the mill operatives of Yorkshire and Lancashire is carious teeth, with its accompaniment oral sepsis. I am also firmly convinced that the early and thorough medical treatment of gastric ulcers and the surgical treatment of those that prove rebellious, either by gastro-entrostomy or excision, would do much to lessen the amount of cancer in the stomach.

NOTE.—A clinical lecture by a well-known teacher appears in each number of the journal. The lecture in next week's number will be by Sir Christopher Nixon, entitled, "The Diagnostic Value of Alterations of the Pulmonary Second Sound."

CLINICAL LECTURES FOR 1906.

We have already been favoured by promises of Clinical Lectures from the following teachers:—

- JOHN H. ABRAM, M.D., Lond., M.R.C.P., Lecturer on Clinical Medicine University of Liverpool
- WM. ALEXANDER, M.D., R.U.I., F.R.C.S., Eng., Lecturer on Clinical Medicine, University of Liverpool.
- PROF. CLIFFORD ALLBUTT, M.D., F.R.C.P., Lond., F.R.S., Regius Professor of Physic, University of Cambridge.
- SIR C. BALL, F.R.C.S.I., Regius Professor of Surgery, Dublin University.
- SIR JAMES BARR, M.D., F.R.C.P., Lond., Physician, Royal Infirmary, Liverpool.
- H. T. BRAWLEY, M.D., F.R.C.P.I., Lecturer on Public Health, School of Physic, Dublin.
- LEONARD A. BIDWELL, F.R.C.S., Eng., Surgeon to the West London Hospital.
- SIR LAUDER BRUNTON, Bart., M.D., F.R.C.P., F.R.S., Cons. Phys., St. Bartholomew's Hospital.
- JAMES CANTLIE M.B., C.M., F.R.C.S., Surgeon, Seaman's Hospital Society.
- ALBERT CARLESS, M.B., Lond., F.R.C.S., Eng., Surgeon to King's College Hospital.
- PROF. WM. CARTER, M.D., F.R.C.P., Lond., Prof. Mat. Med., University of Liverpool.
- SIR ARTHUR CHANCE, F.R.C.S.I., President Roy College Surgeons, Ireland.
- ANDREW CLARK, D.Sc., Oxon., F.R.O.S., Surgeon to the Middlesex Hospital.
- THOMAS S. CLOUSTON, M.D., F.R.C.P., Ed., Lecturer on Mental Diseases, University of Edinburgh.
- JAMES CRAIG, M.D., F.R.C.P.I., Physician to the Meath Hospital.
- SIR J. HALLIDAY CROOM, M.D., Ed., F.R.C.P., Cons. Gynaecologist, Royal Inf., Edinburgh.
- W. J. DAROGAN, M.D., Physician to St. Vincent's Hospital.
- GEORGE A. GIBSON, M.D., F.R.C.P., F.R.S.E., Examiner in Clin. Med., University of Edinburgh.
- ARTHUR E. GILES, B.Sc., Lond., M.D., F.R.C.S.E., Surgeon, Chelsea Hospital for Women.
- T. E. GORDON, F.R.C.S.I., Surgeon to the Adelaide Hospital.
- A. PEARCE GOULD, M.B., Lond., F.R.C.S., Surgeon, Middlesex Hospital.
- W. S. HAUGHTON, M.D., Surgeon to Steevens Hospital, Dublin.
- O. O. HAWTHORNE, M.D., M.R.C.P., Lond., Phys. Cent. Lond. Ophthalmic Hospital.
- A. J. HOENE, F.R.C.P.I., Master of the National Lying-in Hospital.
- ROBERT HUTCHISON, M.D., F.R.C.P., Lond., Asst. Phys. London Hospital.
- ALEXANDER JAMES, M.D., Ed., F.R.C.P., Phys. to the Edin. Royal Infirmary.
- H. LEWIS JONES, M.D., Cantab., F.R.C.P., Lond., Phys. Electrical Department, St. Bartholomew's Hospital.
- ROBERT JONES, F.R.C.S., Ed., Surgeon to the Liverpool Royal Southern Hospital.
- CHARLES R. B. KEETLEY, F.R.C.S., Eng., Senior Surgeon, West London Hospital.
- J. A. LINDSAY, F.R.C.P., Professor of Medicine, Queen's College, Belfast.
- JOHN MACINTYRE, M.B., C.M., F.R.M.S., Surgeon for Diseases of the Throat and Nose, Glasgow Royal Infirmary.
- R. C. B. MACNELL, F.R.C.S.I., Surgeon to Mercer's Hospital.
- A. B. MITCHELL, F.R.C.S.I., Surgeon Royal Victoria Hospital, Belfast.
- THOS. K. MONRO, M.D., M.Ch., F.F.P.S., Glas., Physician and Clinical Lecturer, Glasgow Royal Infirmary.
- ALEX. MORISON, M.D., F.R.C.P., Lond., Physician, Gt. Northern Central Hospital.
- WM. MURRELL, M.D., F.R.C.P., Lond., Physician to the Westminster Hospital.
- SIR C. NIXON, M.D., F.R.C.P.I., Prof. of Practice of Medicine, Cath. Univ. School of Medicine.
- J. F. O'CARROLL, M.D., F.R.C.P.I., Physician to the Richmond, Whitworth and Hardwick Hospitals.
- FRANK THOS. PAUL, F.R.C.S., Eng., Surgeon, Liverpool Royal Infirmary.
- R. W. PHILIP, M.D., F.R.C.P., Ed., Examiner in Clin. Med., Edinburgh University.
- F. J. POINTON, M.D., F.R.C.P., Lond., Asst. Phys., Hospital for Sick Children.
- A. MAITLAND RAMSAY, M.D., F.F.P.S., Glas., Surgeon, Ophthalmic Inst., Glasgow.
- PROF. A. W. MATO ROBSON, F.R.C.S., Hunterian Professor R. C. Surgeons, Eng.
- E. MARKHAM SHERRITT, M.D., F.R.C.P., Lond., Professor of Medicine, Univ. College, Bristol.
- R. SINGLETON SMITH, M.D., F.R.C.P., Lond., Cons. Physician, Bristol Royal Infirmary.
- WALTER SMITH, M.D., F.R.C.P.I., King's Professor of Mat. Med., Trinity College, Dublin.
- SYDNEY STEPHENSON, M.B., C.M., F.R.O.S.E., Ophth. Surgeon, Evelina Hospital.
- J. LINDSAY STEVEN, M.D., F.F.P.S., Glas., Physician and Lecturer on Clinical Medicine, Glasgow Royal Infirmary.
- H. R. SWANZ, F.R.S.S.I., Surgeon, Royal Victoria Eye and Ear Hospital.
- J. ODERY SYMES, M.D., Lond., D.P.H., Bacteriologist, Bristol General Hospital.

- W. TAYLOR, F.R.C.S.I., Surgeon to the Meath Hospital, Dublin.
- J. LYNN THOMAS, C.B., F.R.S.S., Eng., Surgeon to the Cardiff Infirmary.
- R. F. TOBIN, F.R.C.S.I., Surgeon to St. Vincent's Hospital, Dublin.
- E. H. TWEEDY, F.R.C.P.I., Master of the Rotunda Hospital, Dublin.
- HENRY WALDO, M.D., Aberd., M.R.C.P., Lond., Physician, Bristol Royal Infirmary.
- H. F. WATERHOUSE, M.D., Ed., F.R.C.S., Eng., Surgeon, Charing Cross Hospital.
- SIR JOHN B. TURK, M.D., F.R.C.P., F.R.S.E., Morison Lecturer on Insanity.

ORIGINAL PAPERS.**PARALYSIS OF THE ABDOMINAL MUSCLES FROM ACUTE ANTERIOR POLIOMYELITIS.**

By J. S. FOWLER, M.D. F.R.C.P.Ed.

Extra Physician, Royal Hospital for Sick Children, Edinburgh.

PARALYSIS of the abdominal muscles is unquestionably a rare occurrence in acute anterior poliomyelitis. It is unmentioned even in recent text books, and very few examples are recorded in neurological literature. No doubt the presence of the more conspicuous and incapacitating palsy of the limbs has to some extent contributed to this less obvious paralysis having escaped notice, and, like many other symptoms, it will probably be found to be more common than has been supposed when once its existence is more generally realised, and it is in view of this that I am induced to report the following case.

The patient was a girl, *æt.* 2 11-12, of satisfactory personal and hereditary antecedents. When she was two years and three months old she was suddenly seized with what is described as a "stomach attack," in which she lay drowsy and listless for a couple of days; this was followed by a day or two of good health, after which she was again taken ill and became almost completely paralysed, the only movements remaining possible being those of the head and eyes. There was no fever, unconsciousness, or convulsion. The paralysis persisted without change for a fortnight and then power was gradually regained in the right arm and left leg, so that in about six weeks she could move them fairly well. The left arm and right leg remained weak and almost useless, though latterly they too have improved somewhat, and the child can now stand and walk a little, though only with support. Within the past two months spinal curvature has developed. On examination the patient was found to be healthy in all respects save as regards the nervous system. She can neither walk nor stand without assistance; as a rule she rolls about the floor and cannot rise to a sitting posture without pulling herself up by her hands. She can flex both thighs on the abdomen, and the legs on the thighs, and can extend both legs; all these movements are fairly well carried out by the left leg, but decidedly feebly by the right. The greatest degree of paralysis is shown by the extensors of the right foot, which hangs in a position of foot-drop, and cannot be dorsiflexed voluntarily. Both knee jerks are slightly present; the plantar reflexes are doubtful. The muscles of the right leg below the knee are wasted, and the limb is cold. In both arms gross movements are well executed, but the finer movements of the hands and fingers (as in picking up small objects) are clumsy. The grip is good in the right hand, feeble in the left, which is in the position of *main en griffe*, the lumbricals and interossei being wasted.

The most remarkable feature of the case, however, is the condition of the abdomen. When the child is quiet little abnormal is noticeable, except that the abdomen bulges forward unduly with the descent of the diaphragm, but when she strains as in crying, this bulging becomes much more evident, the whole belly swelling up like that of a frog. On palpating the abdomen there is none of the usual resistance of the muscles, which

feel soft and relaxed. When the child tries to sit up she falls in the attempt, and the hand placed on the abdomen detects no contraction of the muscles. The abdominal reflexes are absent. The umbilicus is not displaced to either side. There is also paralysis of the dorsal muscles, causing well marked scoliosis.

The electrical reactions could not be satisfactorily tested (indeed, in children these can seldom be determined accurately except under general anaesthesia, which was impracticable in the present case), but the small muscles of the left hand, and the extensors of the right foot, showed marked diminution in excitability to the faradic current.

The case may be summarised as one in which the original loss of power was exceptionally widespread, and the residual paralysis, after 8 months, was chiefly localised in the extensors of the right foot, the abdominal and trunk muscles, and the small muscles of the left hand.

Even apart from anterior poliomyelitis, very little attention had been paid to the clinical features of paralysis of the abdominal muscles until Oppenheim's paper (1) on "The Abdominal Symptom-complex" appeared in 1902. Palsy of the muscles of the abdominal walls, he found, might arise from neuritis or from a cord lesion, such as a tumour, the chief symptoms being (1) inability to strain effectually, and bulging of the abdominal walls on attempting to do so; (2) displacement of the umbilicus to the sound side, when the lesion was unilateral; (3) inability to sit up without the help of the hands in bilateral cases; and (4) absence of the abdominal reflexes over the paralysed area. The paralysis in Oppenheim's cases was neither circumscribed nor limited to any one muscle, but affected all the muscles of the abdominal parietes, including the recti, either unilaterally or bilaterally, as the case might be. The segments of the cord which supply the muscles in question are the 8th to the 11th dorsal. Two papers on abdominal paralysis from anterior poliomyelitis have recently appeared, the more important being that of Ibrahim and Hermann (2), which is a study of four cases, while Cornell (3) also reports a case.

As might be expected, it is usual to find that the muscles of the back are affected along with those of the abdomen, but no other grouping is specially characteristic. The case reported above is the only one in which a residual crossed paralysis of the limbs was present. As has been mentioned, Oppenheim states that in neuritis or tumour of the cord, &c., the whole of one or both sides of the abdomen are paralysed or paretic. Ibrahim and Hermann find, on the other hand, that in infantile palsy a more limited paralysis is the rule, leading ultimately as in one or two other cases previously recorded, to a circumscribed atrophy with hernial protrusion of the viscera. A point on which these writers also lay stress is that, in contra-distinction to Oppenheim's cases, the recti are spared. The above cases conform more closely to the abdominal symptom-complex of Oppenheim than to the cases described by Ibrahim, Hermann, and Cornell, in respect of the wide distribution of the paralysis. As far as could be determined, all the abdominal muscles were paralysed, including the recti; the bulging was no greater on the one side than on the other, and the abdominal walls were everywhere equally flaccid. It should, however, be said that the child was very well nourished, and it must be borne in mind that owing to the uniform distribution of the palsy one was deprived of the advantage of being able to compare a sound with a paralysed part. It is quite possible, therefore, that the paralysis was not absolutely complete throughout all the muscles, and that as time goes partial recovery may take place, leaving a more or less circumscribed area of local atrophy. Ibrahim's third case, when examined two months after the onset, showed a state of matters not very dissimilar to that in mine, both sides of the abdomen being paralysed and having their reflexes abolished, though the right was the more severely affected. Six years later, however, the

paralysis had become circumscribed, and gave rise only to a globular protrusion of the viscera on straining.

Although rare, the condition is not destitute of practical importance. We are so habituated to regarding infantile paralysis as devoid of danger to life, that a favourable prognosis is usually given in this respect; at least after the acute onset is over. But when extensive paresis of the abdominal and trunk muscles is present, the risk to the patient should he be attacked by any acute pulmonary affection must be considerable. On the other hand, there is evidently a fair prospect that the function of the abdominal muscles will, partly at least, be restored, for in two of Ibrahim's cases considerable improvement was manifest after some years had elapsed.

THE SUBCUTANEOUS INJECTION OF SEA WATER IN THE TREATMENT OF INFANTILE DEBILITY.

By M. O. MACE,

Obstetrical Physician to the Paris Hospitals;

AND DR. R. QUINTON,

Assistant in the Laboratory of Physiology and Pathology of the College of France.

THE success that has attended the subcutaneous injection of artificial serum in prematurely born and feeble infants is now generally known. For some time past attention has been directed to the results obtained by the use of salt (sea) water with the same object in view. In view of the manifest superiority of sea water over ordinary artificial serum it occurred to us to make use of it as a substitute for the serum in the same class of cases. We therefore undertook a series of observations in order to test this hypothesis, and although in the space at our disposal we cannot go into detail we can at any rate give the general results which may conceivably induce others to follow our example.

Our investigations were carried out in the wards allotted to feeble infants at the Paris Maternity Hospital. They bore on 40 infants, and we wish to lay special stress on the fact that they were 40 feeble infants, peculiarly weak or presenting some hereditary taint, brought to the hospital in an extremely precarious state of health, as evidenced by the very trifling gain in weight prior to the commencement of the treatment—viz., an average of 25 grains per day per infant.

The majority of these prematurely born and feeble infants were suffering from the usual infantile diseases—bronchitis, diarrhoea, icterus, athrepsia, etc. We may lay it down, to begin with, that sea water, far from proving injurious in any possible way, appeared to us to considerably curtail the duration and diminish the gravity of the morbid phenomena. It caused the disappearance of jaundice usually in a comparatively short space of time. On no occasion did we see enteritis persist beyond five days under the sea water treatment even when originally severe. Respiratory affections were also favourably influenced thereby.

Lastly, in the subjects who were purely feeble without other morbid complication the subcutaneous injection of sea water yielded excellent results, rapidly causing the subsidence of all manifestation of debility, such as chilliness, cyanosis, digestive troubles and the like.

Even more convincing than these considerations was the prompt gain in body weight under the influence of the injections as compared with that following the employment of artificial serum, so largely used at the present time. We mentioned above that the average daily increase of weight in our little patients was 25 grains. With injections of artificial serum the gain per day per infant rose to 85 grains, whereas with sea water injections the daily gain amounted to 140 grains,

the other circumstances and conditions being exactly the same.

It follows that the gain in weight, which affords us such a trustworthy indication of functional activity, is double under sea water injections of that which follows the injection of artificial serum and ten times greater than during the "expectant" period. These averages are based on 2,132 days' experience, a fact that will give a good idea of their relative value. No œdema has ever been observed to follow the treatment.

Technical Details—Doses—Intervals. In conclusion we will describe the precise mode in which the treatment was carried out. With infants of an average weight of four pounds we injected every second day 10 cc. (about 180 minims) of isotonic sea water, preferably just below the scapula. We attach great importance to the dose and the interval. Recent researches, indeed, seem to point to a certain timidity in the use of sea water on the part of some practitioners, timidity which there is nothing to justify; indeed on the contrary, when administered in homeopathic doses, sea water gives no results worth mentioning. Nothing less than the quantity specified can be trusted to bring about an improvement.

This dose of 10 cc. every second day, though sufficient for prematurely born infants weighing four or five pounds, is inadequate when we have to deal with older children weighing from eight to twelve pounds. The injections should not be given oftener than every second day, but the dose may advantageously be increased to 30 cc. and upwards.

It has been pointed out that sea water is the culture medium for organic cells. It is absolutely devoid of toxicity and the white corpuscles thrive therein as if to the manner born. An animal may be injected with more than its body weight of sea water (Hallion) without causing the least sign of injury. Doses of 10 cc. for infants represent a minimum below which it is undesirable to descend if we wish to obtain tangible results.

A CASE OF RAYNAUD'S DISEASE.*

By S. T. LIGHTFOOT, L.R.C.S., L.R.C.P.ED.,
L.F.P.S.GLASG.

THE following case of Raynaud's disease, which came under my notice in private practice, presents some features of somewhat unusual interest. The diagnosis was confirmed in consultation both by a physician and by a surgeon. The result of the operative removal of the three affected fingers by the Bilton-Pollard method is extremely good.

History.—Mrs. A. H., widow, æt. 62, came to me on February 17th, 1903, complaining of severe pain and tingling in fingers of both hands. Some five or six years before the patient came under notice, she was suffering from albuminuria, which was cured with some difficulty. In the early spring of 1901, she had severe bronchitis and pleurisy, which left her in a nervous, irritable state. In July, 1901, she left London for Watford, and at first greatly improved in health. But her health fluctuated, a little albumin appearing occasionally in the urine. In the winter of 1902, she was in a very run-down and nervous state. Complained greatly of cold hands on rising. They ached and looked white and bloodless after washing, but regained normal appearance and feeling after a short time. Patient got worse in general health.

Patient was confined to the room and was in a depressed state, with frequent fits of crying. Took to her bed. Complained that everything looked strange and distorted, and appeared edged with bright beads, and seemed in a yellow mist. Wandered somewhat in mind and talk, but was conscious of the strangeness of her fancies, and would frequently laugh at their absurdity.

Patient now began to complain greatly of pain and tenderness in finger-tips of right hand, but no change

was visible in them. Pain changed to acute stabbing. Several times appeared in both hands at once, then in left hand alone; finally in right hand alone, where it remained.

History of Attack.—A faint purple tinge afterwards appeared in the fleshy parts of the right finger-tips. It looked as if the bone were purple, and the flesh sufficiently transparent to allow a slight indication of the colour to be seen. Agonising pain at frequent intervals for half-an-hour or so at a time. Finger tips began to darken, particularly round the nails, which developed a black spot in the centre of each. Thumb swelled up and joints swelled. Under surface of finger tips became harsh to the touch and turned a dirty brown, which colour extended nearly to second joint. Backs of fingers varied somewhat in colour. Sometimes they were mottled with dark, angry red and purple; sometimes only a little redder than normal, down to second joint. First joints steadily got worse, and did not vary save to get blacker. Fingers generally were discoloured for greater distance on palmar than on dorsal aspect.

After this had lasted a few days I noticed the appearance of a network of purplish red mixed with bluish capillaries, which increased gradually, until the tips of the fingers looked more like a dark blue stain, ultimately resembling on both hands the fingers of a person who had been picking blackberries. The patient suffered for some time agonising pain in the fingers, which nothing would relieve. I applied a variety of stimulating anodyne liniments, and kept both hands well covered with cotton wool. Under this treatment the left hand slowly recovered, but the right became gradually worse, and was not amenable to the same treatment. Neither hand could endure exposure to cold air, as it produced intense pain, which was temporarily relieved by hot fomentations and poultices. With regard to the duration of pain in the

* Shown at a Clinical Meeting of the Association of Medical Diplomates of Scotland, Dec. 12th, 1905.

right hand, it was never entirely absent for three months. The pain was always greater in the evening and night.

Dr. C. Herbert Hall, of Watford, saw the patient in consultation on two occasions, April 11th and 16th, and confirmed the diagnosis of Raynaud's disease. We agreed to advise amputation of three fingers. After this the hand was photographed, showing the exact condition of the fingers at that time. You will see that all five fingers were involved. Fortunately the thumb and fore-finger recovered completely.

On May 5th the patient was seen by Mr. Bilton Pollard at University College Hospital. He also confirmed the diagnosis recommending amputation of three-fingers as the others had begun to recover. On May 8th Mr. Bilton Pollard removed the fingers at the metacarpo-phalangeal joints. He noticed that there was very little bleeding during the operation, which he said was usual in Raynaud's disease. Since the operation, now two and a half years ago, the patient has had no return of the symptoms and finds the remaining thumb and fore-finger very useful.

CLINICAL RECORDS.

NOTES ON THREE CASES OF CONGENITAL DISLOCATION OF THE HIP*

By ANDREW FULLERTON, M.D., F.R.C.S.

Hon. Assistant Surgeon Royal Victoria Hospital, and Belfast Hospital for Sick Children, Examiner in Surgery R.C.S.I.

CASE 1.—S.T., female, æt. 2 years and 1 month, was admitted to the Royal Victoria Hospital on account of a "lurching" in her gait. There was no history of injury to mother or child either before or after birth. No deformity of any kind was known to have been present in any member of patient's family. The mother noticed that when the child began to walk its gait was peculiar, and she brought it to hospital to ascertain the cause. On examination the patient was found to be a healthy female child. On walking, she rolled over to the right side and had a very distinct limp. The trochanter on the affected side stood out prominently, and rode on the ilium with each step. The right leg was an inch and a half shorter than the left, but was not wasted. The trochanter of affected side could be felt below and behind the anterior superior iliac spine, and was about $1\frac{1}{2}$ inches above Nélaton's line. It could, however, by traction be brought down to the extent of $\frac{3}{4}$ inch. The head of the femur was freely movable on the ilium. The displacement was upwards and backwards.

Operation.—On May 13th, 1904, the following procedure was carried out under chloroform: (1) Forcible abduction with kneading and percussion to stretch or lacerate the tense adductors. (2) Maximal flexion, with pushing of the head of bone downwards towards perineum to stretch glutei and other muscles tending to draw femur up. (3) Extension and counter-extension to stretch the above muscles with the iliopsoas and hamstrings; also to bring the head of the bone towards the acetabular cavity. (4) Abduction and external rotation assisted by the hand of the operator guiding head towards articular cavity. A sudden snap, audible and easily felt, indicated reduction. At this moment the leg became somewhat flexed on the thigh owing to the shortness of the hamstrings. The head was bored into the acetabular cavity by firm pressure so as to fix it more securely by making a deeper bed for its reception. The limb was put up in the fully abducted position with flexion at hip and knee joints and retained in that position by plaster of Paris bandages. The bandages were changed in a month owing to being soiled, and head of bone slipped out. It was, however, easily reduced. Fresh plaster was applied, and changed first monthly and later at rarer intervals for a period of nine months altogether. At each change the limb

was brought more and more into the normal position, until finally it was quite straight. The child was after the first few weeks allowed to walk, so as to push the head of the femur against the shallow acetabulum and deepen it. The patient was examined on December 14th by the members of the Ulster Medical Society—that is one year and seven months after operation—and the limb was found to be anatomically and functionally perfect. The skiagraphs taken before and after reduction show the characteristic deformity and its complete reduction.

CASE 2.—W.M., male, æt. 8. No history of injury, was noticed to limp when he began to walk, which he did not do till he was æt. 3.

On Examination.—The boy walked lame and had a huge thick sole on his right boot to make up for a very obvious shortening of his right leg. The limb was not so well developed as the left, but there was no loss of power but rather considerable facility of movement. The affected leg was $2\frac{1}{2}$ inches shorter than its fellow, and the trochanter raised above Nélaton's line. The limb could be lengthened to the extent of $\frac{1}{2}$ inch by traction. The movements of the head of the bone at the false joint were very free and painless. The head of femur could be felt almost on a level with the anterior superior spine, and was set further back than on the sound side. The trochanter was prominent. The skiagraph showed the femur to be considerably smaller in diameter than its fellow of the opposite side. The head and trochanter were also attenuated; the former looked like the truncated end of the neck. The acetabulum was shallow and ill-developed. From the skiagraph it would appear that the angle between the neck and shaft is increased on the affected side. No treatment has yet been adopted.

CASE 3.—J.R., æt. 12, was seen on May 9th, 1904. She was a typical example of double congenital dislocation at the hip-joints. Walked with a marked waddling gait. Trochanters could be felt high up on ilium, $2\frac{1}{2}$ inches above Nélaton's line, and posterior to acetabulum. On placing the hands on hips and asking the patient to walk, the up and down movement of the trochanters could be plainly felt. The hips were broad and the trochanters projected in a characteristic manner. The thighs were separated by about an inch at the perineum. There was marked lordosis. The femoral neck on both sides was short and thick as seen by skiagraph, the upper end of the bone resembling that of a humerus rather than that of a femur. There was no indication of an acetabulum on either side in the skiagraph. On traction, the heads of the femora could be drawn down to the extent of about an inch when the patient was lying down. As the girl can get about very comfortably her parents have decided not to submit her to operation.

THE OUT-PATIENTS' ROOM.

THE CANCER HOSPITAL.

Two Cases of Melanotic Sarcoma Commencing in Pigmented Moles.

Under the care of R. H. JOCELYN SWAN,
M.S.LOND., F.R.C.S.
Assistant Surgeon to the Hospital.

Case I.—M.A.W., female, æt. 56, was sent to the Cancer Hospital in May, 1905, for tumours in the abdominal wall, right inguinal region, right breast, and axillary glands. She has had slightly raised, pigmented mole on the right side of the abdominal wall in the mammary line at the level of the umbilicus as long as she could remember. It caused her no inconvenience, but about two years ago she noticed that it had gradually increased in size, forming a raised, rounded boss, covered by thin purple skin, which finally ulcerated, leaving a surface from which bleeding was easily provoked on touching. Twelve months later

* Shown at a meeting of the Ulster Medical Society, Dec. 14th, 1905.

this was removed by a doctor by an elliptical incision, and the wound healed well, but in November, 1904 (six months later), she noticed, under the outer end of the scar, a thickening which progressively increased in size, and extended into the subcutaneous tissues on either side of the scar. About the same time the patient also noticed a tumour in the right inguinal region, and in the upper and outer quadrant of the right breast. The inguinal swelling slowly increased in size, but caused no pain other than an occasional aching in the groin. The mammary tumour had enlarged more rapidly, and caused a shooting pain in the right shoulder and axilla.

On examination, on the right lateral aspect of the anterior abdominal wall was the horizontal scar of the previous operation, the outer end of which was stretched by an underlying tumour, nodular on the surface, and covered by thin, pink-coloured skin, in which many dilated venules were seen. The tumour formed a plaque with raised, rounded edges, and was of firm consistence. It was not adherent to the abdominal muscular planes.

The inguinal tumour was a mass of enlarged lymphatic glands, matted together, forming a swelling the size of a hen's egg. The skin over it was freely movable, and the mass was not adherent to the deep structures.

The right breast contained a firm, oval-shaped, flattened swelling, immovable in the mammary tissues, in the upper and outer quadrant of the organ. The skin over it was dimpled and adherent to it in the centre, and on attempting to raise it between the fingers showed the "peau d'orange" type. The limits of the tumour were indefinite, and it was adherent to the pectoral fascia. There were enlarged glands in the right axilla, but the glands in the cervical, supra-clavicular and infra-clavicular regions were not affected. The liver was not palpable, and no physical signs were present in the thorax.

A diagnosis of melanotic sarcoma was made, and the patient was admitted to the hospital for operation, which was performed on May 23rd, 1905. The right breast and axillary contents were removed by Halstead's operation, the costo-sternal portion of the pectoral muscles being removed, and the axillary sheath and costo-coracoid membrane dissected away. The recurrent nodule in the abdominal wall was removed at the same time, the inguinal mass being also extirpated. The immediate progress of the patient was wholly satisfactory, and she left the hospital well on July 12th. Pathologically, each tumour consisted of melanotic sarcoma, containing mixed round and spindle-shaped cells. The inguinal and axillary lymphatic glands also showed melanotic deposits.

The subsequent history of the case (kindly supplied by Dr. McConnell) showed that about the middle of August she became hemiplegic. Some time afterwards a tumour appeared in the right iliac fossa, and another to the left and below the occipital protuberance. She became subject to attacks of delirium and delusions, and died on October 12th from pulmonary oedema. No post-mortem examination was obtained.

Case II.—C.C., female, æt. 49, came to my out-patients' room in October, 1905, for tumours of the right side of the face and neck. Since a small child she had had a small pigmented mole below the right lower eyelid. This remained the same form until about fifteen months ago, when it began to increase in size, reaching that of a filbert-nut in three months, when it was removed at the London Hospital by Mr. Hurry Fenwick. She remained well for four months, when recurrence took place at the original site, and two months later she was again operated upon, not only the recurrent nodule being removed, but also the glands in the submaxillary and upper part of the anterior triangle of the right side of the neck were dissected out. Within a month after this operation she again noticed a tumour over the angle of the jaw on the right side, and five weeks later a further recurrence took place under the right eye. These have increased in size, and more recently patient

has found further tumours in the right supra-clavicular region, in the right axilla and in the back.

She was admitted into the hospital on November 2nd, 1905, and on examination at this time there was a raised, rounded tumour below the right eye, the size of a walnut, fixed to the underlying bone, blue in colour, and in its prominent portion the skin over it was very thin and shining. Over the right angle of the mandible was a large, irregularly shaped, nodular mass, fixed to the jaw, and projecting into the mouth opposite the lower molar teeth, but the mucous membrane over it was intact. The glands in the vicinity of the tumour were enlarged. Small subcutaneous nodules of growth were present in the posterior fold of the right axilla and over the back of the seventh dorsal spine. The liver was slightly enlarged but smooth. The physical signs in the thorax were normal.

No operation could be performed for this patient, and her progress in hospital has been rapidly downhill. The facial tumours increased in size and other subcutaneous nodules of growth appeared upon the abdominal and thoracic walls. The breathing has become quickened, and the patient is now apathetic.

The exact nature of the tumours in this case cannot be stated until the histological examination, but in all probability the growth is of a melanotic character. Both these cases are instances of the origin of malignant disease in the life history of an innocent tumour, and they are here brought forward to impress the fact that should an apparently innocent tumour at any time take upon itself progressive or rapid increase in size, or should its surface become ulcerated or bleed, it should be removed whenever possible by an incision carried wide from its apparent limits.

OPERATING THEATRES.

GUY'S HOSPITAL.

CASTRATION FOR TUBERCULOUS DISEASE OF THE TESTIS.—MR. CLEMENT LUCAS operated on a man, æt. 50, for tuberculous disease of both testes. There was a family history of tubercle on both sides, the man's mother and his father's sister having died of the disease. The patient was said to have had enlargement of the left testis seventeen years ago, which disappeared after wearing a suspensory bandage. He had no further trouble till, June, 1905, when the swelling again commenced, and was accompanied by dragging pain on the right side. He was treated in the country, and wore a suspensory bandage, under which the swelling at first seemed to diminish. In October he noticed a swelling upon the left testis, associated with shooting pains. The swelling gradually increased, and burst a fortnight later, discharging thick yellow matter. He was first admitted into the hospital a week afterwards. The left testis was considerably swollen and hard; in front of it was a soft fluctuating swelling, which was translucent, and due to fluid in the tunica vaginalis. On the outside the skin was indurated, and adherent round the spot where the abscess burst. The epididymis throughout was felt to be very much enlarged. The right testis was also very much increased in size, but nowhere adherent to the scrotum. The epididymis formed a large crescent on the outer and back part. Tuberculous disease of both testes, was diagnosed, but as open suppuration had occurred on the left side, it was determined to remove this testis first, together with the infiltrated skin, through which the tuberculous abscess had discharged, and to leave the right testis for a second simpler operation by drawing it up through an incision over the external abdominal ring. An incision, including skin, cellular tissue, and dartos was commenced over the left

inguinal canal, and carried downwards, and back again so as to include an ellipse of the infiltrated scrotum; the testicle was then turned out with this ellipse attached to it, the cord was clamped as high up as possible, severed below the clamp, and the testis removed. The vessels of the cord were all tied separately with fine silk, and before the clamp was removed a temporary stitch was run through the cord above the clamp, so that it should not slip up in the abdomen when the clamp was taken away this precaution being used in case any vessel should have been missed. As no bleeding took place after removal of the clamp the temporary stitch was taken away, and the cord allowed to retreat into the abdomen. This method of securing the vessels is greatly preferable in Mr. Lucas' opinion, to that of tying all the constituents of the cord together inasmuch as the latter method, by including all the nerves of the cord, gives rise to much greater pain, and as a stouter ligature is used may also contribute to suppuration and stitch sinuses. A short time ago, he said, in removing both testes at the same time, he compared the two methods, employing one on one side and the other on the opposite the patient complained of pain only on the side where all the constituents of the cord were tied together. The wound in the patient just operated on healed satisfactorily in about a fortnight, and he left the hospital, refusing to have the right testicle operated on before going home. On examining the specimen removed, two ounces of clear serous fluid were found in the tunica vaginalis. On opening the body of the testis disseminated miliary tubercle was found scattered through it, the larger and older tubercles being at the lower part. The globus minor of the epididymis showed masses of breaking down cheesy tubercle; the globus major showed even larger masses, more advanced in the direction of pus, whilst the central part of the epididymis contained an abscess through which a probe could be passed into the abscess sac beneath the skin, which had commenced to discharge a week before the operation.—The patient was re-admitted to the hospital a month later, the right testis now having gone on to suppuration, and having discharged through the scrotum by two small sinuses. This involved a similar operation to the previous one, a large part of the scrotal integument being implicated and having to be cut away. The degeneration of the epididymis and the breaking down of the tuberculous deposits to form tuberculous abscesses was observed in this specimen as in the last, but there was less evidence of miliary tubercle in the body of the organ. In neither case was there any evidence of the tubercle extending high up along the vas deferens, so that Mr. Lucas hoped that all further extension of the disease had been arrested, this man at present showing no sign of prostatic or vesical tuberculous trouble.

The second case on which Mr. Lucas operated illustrated, he said, the importance of removing a tuberculous testis to prevent extension of the mischief to the prostate, vesiculæ seminales, bladder and kidneys, after which the disease too often proves incurable. It was that of a middle-aged man who fourteen years before had had a blow on his left testis; he stated that the organ did not swell up at once, though it was painful, but some six months later it began gradually to enlarge, then went on to suppuration and discharge. After being some months under treatment the sinus healed but the testis never resumed its normal size and contour, but remained permanently enlarged. For some months before admission the

patient had begun to suffer from extreme irritability of the bladder; he also noticed some turbidity of his urine; he had no stricture or stone in his bladder. Mr. Lucas found the epididymis of the left testis greatly enlarged and the cord above thickened. Examined per rectum, the left side of the prostate was also found enlarged. The case was diagnosed as tuberculous testis, with secondary infection of the prostate, and Mr. Lucas strongly advised the man to have the organ removed. The right testis was found perfectly normal. The operation was performed through an incision over the external abdominal ring and inguinal canal, the testicle being drawn up out of the scrotum by means of the cord; as the vas deferens was also much thickened, the inguinal canal was split up so that as much as possible of the seminal tract should be removed. The vessels were tied separately as in the previous case and the wound completely closed. Primary union took place and a week later the patient began to experience some benefit from the operation as the irritability of his bladder began to subside. Examination of the testis showed the whole epididymis converted into a tuberculous mass, in part crétaceous; similar deposits in fusiform masses were found along the vas deferens. The body of the testis showed fibroid change, the seminal tubes not unravelling. The patient was afterwards treated by the injection of tuberculin at intervals to raise his opsonic index, which greatly improved after removal of the testis. Before he left the hospital, he had gained almost complete control over his bladder. The manner in which the tubercle bacillus reaches the epididymis and germinates there may, Mr. Lucas remarked, vary in certain cases, but he thought that in a good many instances the disease commences as a tuberculous urethritis and extends to the epididymis in the same way as a gonorrhoeal urethritis reaches the same organ. A remarkable instance of this, he said, came under his notice in private practice during the past year, where an insignificant and painless urethritis contracted by illicit congress ended fatally from general tuberculous disease of the urinary tract in about two years and a half. At other times it is probable, he said, that the tubercle bacillus circulating in the blood gets caught in the epididymis of a testis, that has lost its resistance either from injury or injudicious use. The second case operated on, he thought, would appear to be one of the latter, for there was a distinct history of injury, although the tuberculous enlargement did not appear till some six months later when the man was for some reason or another probably depressed in health. Again the extension of the mischief from the testis to the urinary tract did not take place till some years later, when probably some fresh cause depressed the man's general health.

Death of a Lunatic from Choking.

AN inquest was held on Saturday at Colney Hatch Asylum on the death of Alice Solomon, twenty-seven years of age, a patient, who was choked by a piece of plum pudding on Christmas Day. She suffered from mania; was in the habit of taking food from other inmates of the institution, and throwing plates at them; and had to be specially watched, as it was feared she would do violence to herself. A nurse said that she was feeding Solomon at dinner time on Christmas Day. While the woman was eating the pudding she threw back her head suddenly, and was dead before a doctor could reach her. A *post-mortem* examination revealed a piece of the pudding sticking in the throat. A verdict of death from misadventure was returned.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DEC. 15TH, 1905.

The President, Dr. R. D. PUREFOY, in the Chair.

Dr. R. C. B. MAUNSELL showed a uterus removed by Wertheim's method for carcinoma of cervix.

Dr. JELLETT asked if he had found the separation of the uterus, as Wertheim described it, easy? Wertheim said that if the ureter were isolated it sloughed; but when were you not going to isolate it if it ran through or on top of a carcinomatous mass? If this is so, it would seem to be a necessary part of the operation to remove this isolated portion and reinsert the ureter into the bladder. He did not see any difficulty in the rest of the operation.

The PRESIDENT said that in the removal of a cancerous uterus one of the chief things was the safety of the ureters, and this was difficult to provide for. It was an interesting point that so many glands were examined and found to be free from cancer. His own feeling was that the uterus should be removed in every case in which there appeared to be even a slight chance of the patient getting over the operation, and they should try to relieve suffering.

Dr. MAUNSELL, in replying, said that he too thought that the operation should be done if possible, as he believed the suffering was less when a patient died from a secondary growth, as in the liver, than from the primary one. The ureter had to be separated if you were going to extirpate the parametrium, and he would not have the least hesitation in doing it, as he thought there was little danger of sloughing so long as you did not pinch the ureter in any way. He had found it pretty hard to carry out Wertheim's procedure—namely, to lay your finger on the ureter and pass your finger between the ureter and the uterine vessels. There was nothing very difficult in the operation, but it was rather lengthy.

Dr. HASTINGS TWEEDY showed a retro-peritoneal sarcoma.

Dr. ROWLETTE described the pathology of the tumour.

The PRESIDENT described a somewhat similar case in a girl, aged seventeen. There had been steadily-increasing distension of the abdomen for two years. Urine loaded with albumin. Operation revealed a tumour weighing 17 or 18 lbs., in the retro-peritoneal tissue in the region of the left kidney, which was free.

Dr. GOULDING asked if there was a mesentery in connection with the tumour, as it was hard to conceive that the vessels underneath would not otherwise be pressed on.

Dr. TWEEDY, in replying, said that the tumour was absolutely fixed to the spine, and he had been surprised that there was no evidence of pressure on the vessels. This class of tumour could not be diagnosed before the abdomen was opened, and once this was done the surgeon should always complete his operation.

SOME POINTS OF INTEREST IN A SERIES OF TWO HUNDRED AND ELEVEN MAJOR OPERATIONS.

Dr. HASTINGS TWEEDY read a paper dealing with some points of interest in a series of 211 major operations performed by him in the Rotunda Hospital. These comprise 44 ovariectomies, 9 panhysterectomies, 15 sub-total hysterectomies, 14 pyosalpingies, 32 ventrofixations, 2 anterior colpotomies, 11 salpingotomies, 15 tubal pregnancies, 3 ovarian resections, 9 ventral hernias, 7 radical operations for prociencia, 1 tubercular peritonitis, 2 vaginal hysterectomies for painfully retroverted uteri, 2 retroperitoneal sarcomata, 4 Cæsarean sections, 18 vaginal fixations, 7 abdominal myomectomies, 10 vaginal myomectomies, 1 enterostomy

and 5 vaginal hysterectomies for cancer. There were 8 deaths in this series—two under anæsthesia, in profoundly septic patients, 2 in abdominal, and 1 in vaginal hysterectomy for cancer, 1 vaginal myomectomy, 1 sub-total hysterectomy, and 1 abdominal removal of pus tubes. The skin wound showed some suppuration in five cases, staphylococcus albus in two, bacillus coli in one, and a diplococcus in a fourth, whilst the germ was not looked for in the fifth. Convalescence was delayed in none of these cases. Tubal disease, to a greater or lesser extent, was found in 19 of the 32 patients subjected to ventrofixation; nearly all these were sterile, and an effort was made in every instance to remove the pathological state by breaking down adhesions, resecting ovaries, and opening the lumen of the tube. He believed that neither Mackenrodt nor Wertheim had succeeded in establishing their operations for cancer on a permanent basis. Dr. Tweedy dealt with his method of closing the abdomen in layers, and by a means of a leaden plate, and pointed out that in a recent Cæsarean section, undertaken by him for the second time, no trace of silk was to be found, either in the uterine or abdominal walls, nor had any adhesions formed in the neighbourhood of the scars. He described in detail the operative technique in force in the Rotunda Hospital, and the simple and inexpensive design of the theatre. None of his failures were attributed to architectural deficiencies in his operating room, which he believed to be adequate for the requirements of aseptic surgery. In its simplicity it furnishes a crushing argument against the lavish expenditure so fashionable in the present day; an expenditure which has converted the modest workshop of the surgeon into apartments which might well serve as a dazzling advertisement for a quack electrical specialist.

Dr. JELLETT congratulated Dr. Tweedy, and said he agreed with him in his views on theatre expenditure. He also approved of having the windows open during operations. He thought that the sterilising apparatus should be removed to some distance from the theatre, as the air could, at present, be contaminated by it. He was inclined to think that face bags were not really necessary if the operator took proper care of his teeth. Discussing the technique of operating in cases of sterility, especially when caused by closure of ostia of tubes, he asked Dr. Tweedy if he had any reason to think that in a case where the tubal ostium had been glued down to the intestines there was any chance of making it patent again. He himself thought the chance small, and he thought the time might be better employed in removing the fimbriated extremities of the tubes where adhesions were most likely to form. He was much surprised to hear that Dr. Tweedy washed out the abdomen in every case, and asked what his views were on the subject of drainage.

Dr. KIDD asked what method of suturing was used in the cases of ventral hernia. He himself had used the three layer principle with good results. In the case of sloughing myoma, which was removed by morcellation, and which ended fatally, would it not have been better to treat by removal of the entire organ? He thought that many cases of sterility were due to the condition of the male. He approved of wearing a mask, as a certain amount of sputum was kept out of the field of operation by it.

Dr. HORNE agreed that the enormous expenditure incurred in making theatres was to be deprecated. He appreciated the strict asepsis of Dr. Tweedy, and suggested that the nurses also should wear masks. The fact of so many stitch abscesses having occurred showed that no matter what care was taken accidents would happen. He believed that cases of cancer frequently came for treatment when too late, owing to the fact that pain was a late symptom in the disease.

The PRESIDENT said he had not made the use of:

rubber gloves a general practice. Many operators stated that their successes were not materially increased by their use, and the difficulty of manipulation was certainly increased. He asked what Dr. Tweedy considered the indications for operation in cases of recurring displacements. Many of these cases were attended with no symptoms. He utterly disbelieved in vaginal fixation, and thought that after Alexander's operation the ligaments frequently stretched again. He thought there was likely to be trouble after these fixation operations if the woman became pregnant, and supposing the ligaments were strong enough to hold.

Dr. HASTINGS TWEEDY, in reply, said that he had enumerated all his bad cases. Those that remained recovered without causing anxiety. They neither suffered from excessive thirst nor vomiting, from flatulence distension nor obstinate constipation. This he attributed in some part to filling the abdomen with saline. The patients would probably have recovered without the saline infusion, but he felt convinced that there convalescence would have been less uneventful. His series includes 100 consecutive abdominal sections without a death, but this is not a satisfactory record so long as the majority of cancer cases seen are not submitted to operation. The submucous myoma removed by morcellation protruded through the vulva as a sloughing mass, and it was quite out of the question to suggest its removal by abdominal section.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, DECEMBER 14TH, 1905.

CHARLES J. OLDHAM, F.R.C.S., Vice-President, in the Chair.

DR. D. MATHESON MACKAY read a paper on
THE LIGHT SENSE IN STRABISMUS.

After pointing out that up till now, no observations had been made and published on the conditions of the Light Sense in the Amblyopia of Strabismus, he described his examination of 1,245 strabismic or amblyopic patients, undertaken in order to discover if there were any defect in the light minimum, or the light difference, of the affected eye, which could account for the strabismus or the amblyopia. The photometer employed was a new one, described as having several advantages over those previously used. The cases were arranged in six groups, convergent strabismus with amblyopia (66 cases), convergent strabismus without amblyopia (30 cases), alternate convergent strabismus with double amblyopia (2 cases), divergent strabismus with amblyopia (9 cases), divergent strabismus without amblyopia (4 cases), and amblyopia without strabismus (14 cases).

In all these cases both the light minimum and the light difference were estimated separately, and the results in the more important groups showed that a large majority of the affected eyes had normal light sense (77 to 90 per cent., as to the light minimum, and 75 to 80 per cent. as to the light difference). The lesser groups had the same tendency, but on account of the small number of cases, their results were not insisted upon. Dr. Mackay concluded that one could only deduce from these observations that the condition of the light sense is not responsible for the squint, or for the amblyopia.

Mr. STEPHEN MAYOU read a paper on
CYCLOPS.

The specimens, four in number, were obtained at the London Hospital through the kindness of Dr. Keith. Case 1 was that of cyclops in a dog. It showed a single centrally placed eye, having only one elongated lens, and a single retina. The optic nerve consisted of two layers of cells. Case 2 was a human cyclops, having two lenses corneæ and retinae, with a single optic nerve. This specimen was peculiar in having

no proboscis or olfactory nerve. Case 3 was a human cyclops with extreme microphthalmos. It had two lenses and corneæ, and there was a partial inclusion of the proboscis between the anterior parts of the globes. The posterior halves of the ventricles were converted into a large cyst (local hydrocephalus). Case 4 was a twin cyclops, with complete union of heads, and fusion between the eyes of either foetus; the fusion was so perfect that no differentiation could be made out except a small coloboma of the nerve sheath.

Full anatomical details of the results of the mal-development of the first cerebral vesicle, together with the microscopic anatomy of the eyes were given.

RETRO-OCULAR TUMOUR.

Mr. RICHARDSON CROSS gave a description of seven cases he had operated upon for retro-ocular tumour, five of them were done by Kronlein's method. He described the various conditions in which an exploratory operation such as this would be of the greatest benefit; it assisted the diagnosis and left the patient no worse for having done it. The operation was briefly explained.

Case 1 was a fibro-adenoma of the lachrymal gland, but it left behind ptosis and partial paralysis of the ocular muscles with inversion of the eyeball, an unsatisfactory result. Case 2 was a hydatid cyst removed from the optic nerve. This was removed with good result. Case 3 was a fibro-fatty tumour of the eyeball which passed backwards into the orbit. It was removed successfully. Case 4 was a sarcoma of the upper lid, which caused proptosis. The eyeball had to be removed with the tumour, as it happened, although there seemed a reasonable probability that the eye might be saved before the operation was undertaken. The patient made a good recovery. Case 5 was a similar growth under the upper lid in which the orbit was eviscerated without any attempt having been made to save the eye. Case 6 was a large growth at the inner and lower part of the orbit, which was removed by an incision along the inner and lower walls of the orbit. Case 7 was one of severe proptosis, with retro-ocular growth treated by Kronlein's method. A sarcomatous mass had destroyed the upper wall of the orbit, and was in contact with the brain. The antrum was also involved. The wound healed up and left good vision, and good use of the eyeball, even the internal rectus was not damaged. Mr. Cross showed another case in which he considered an exploratory operation desirable. He was greatly impressed with the utility of the operation, and he urged that it should be done in any case in which there was doubt as to the nature of the condition of the orbit.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DEC. 14TH, 1905.

SIR JAMES BARR, President, in the Chair.

DR. W. B. WARRINGTON read a note on some
UNUSUAL CASES OF SPINAL RIGIDITY,

commonly considered as forms of arthritis deformans. He related the history of a man who, after a trivial injury, rapidly developed marked rigidity of the whole of the spine, which was bent forwards, and the head flexed upon the neck. A sister of this man also suffered from a similar condition. The cases were compared with those described by Marie, as spondylose rhizomélisque, and contrasted with the form of rigidity associated with pronounced lesions of the nervous system, first described by Von Bechterew, and by him considered as primarily a nervous disease. Dr. Warrington then gave an account of the neuralgic forms, described by Forrester, and related a case of simple curable rigidity of the spine. It was suggested that in some of these cases the joints of the articular processes of the vertebrae might be the site of the disease, and that the spinal meninges became affected by direct continuity of the morbid process.

Mr. D. DOUGLAS-CRAWFORD related the case of a

girl, æt. 18, in whom, as the result of an accident, the musculo-spiral nerve had been divided. At an operation performed six weeks later there was some difficulty in finding the ends of the divided nerve, which were lying three inches apart. The operation was performed in the country, and as it was impossible to directly join the divided nerve, a young rabbit was shot, and a portion of its spinal cord used to bridge over the gap. Four months later the patient had complete return of sensation, and extension of the digits and supination of the forearm were almost perfect.

Dr. C. J. MACALISTER related a case of Mitral Disease in which a loud vibrating systolic murmur was present. This murmur varied greatly in intensity, almost disappearing during expiration and being very marked during inspiration. There were occasional attacks of tachycardia, the pulse rate at these times varying from 180 to 200 per minute. At the autopsy the mitral cusps were found partly joined by shortened cordæ tendinæ. The left vagus was adherent to the aorta, and was involved in some adhesions behind an atheromatous patch in the vessel, which was narrowed in calibre just beyond the origin of the great vessels. This constriction had probably helped to increase the blood-pressure in the heart during systole, especially during the expiratory act, and in consequence the mitral valve was then more completely closed and the murmur lessened.

Dr. JOHN HAY read a paper on

PAROXYSMAL TACHYCARDIA,

which he illustrated by numerous pulse-tracings and diagrams. Attention was particularly directed to three cases:—Case 1, a youth, æt. 19, had suffered from seventeen attacks which were typical in character, the pulse frequency being between 160 and 300. Between the attacks the action of the heart appeared to be normal in every respect. Case 2, a child, æt. 6, with no valvular disease. There had been one attack only, which varied from the usual type chiefly in its prolonged manner of termination. The pulse frequency during the attack was from 200 to 340 per minute. Case 3, a man, æt. 42, suffering from mitral stenosis, and liable to paroxysms of tachycardia, in which the heart frequency was from 160 to 180 per minute. Dr. Hay discussed the conjectures as to the pathology, and was of opinion that the evidence tended to show that the primary seat of the disorder is situated in the myocardium, that in these persons the heart is unstable in its method of contraction, the exciting factor being some cause initiating stress in the right side of the heart. As a result of this stress, there is a sudden and fundamental change in the manner of the heart's contraction, the auricle and the ventricle contracting simultaneously, each responding to stimuli originating in the fibres joining the auricles to the ventricles. Dr. Hay described the "normal venous pulse" and demonstrated its departure from the normal in cases of paroxysmal tachycardia. In Case 1 there was present that rare and significant form, the "pulsus alterans." It is an evidence of failure in the contracting power of the heart. In Cases 1 and 2 the typical pulsus paradoxus was present on several occasions. Treatment was considered and the various methods discussed. It was recognised that though much could be done for the patient, the attacks tend to follow their own course towards recovery, irrespective of medicinal treatment.

Dr R. J. H. Buchanan, Mr. Damer Harrison, the President, and Dr. P. F. Tinne took part in the discussion.

A Proposed Memorial to Harvey.

An appeal, which will secure the sympathy of medical men, from the Vicar of Hempstead, in Essex, who desires to honour the birthplace of William Harvey, the discoverer of the theory concerning the circulation of the blood. His proposal is to rebuild the church tower at a cost of £1,500. The Royal College of Physicians of London has decided to give twenty guineas. The medical profession generally may, or may not, support this somewhat impersonal memorial.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

A MEETING HELD DEC. 15TH, 1905.
Dr. LEONARD GUTHRIE in the Chair.

The discussion on the BACTERIOLOGY AND PATHOLOGY OF PLEURAL EFFUSIONS was opened by Dr. J. G. EMANUEL (Birmingham). Serous are four times as common as purulent effusions in adults, but in children they occur in practically equal numbers. In adults a purulent effusion is often secondary to a serous, but in children it is generally purulent from the first; 75 per cent. of empyemata are pneumococcal, and these may be either secondary to pneumonia or primary. Streptococcal empyema is rare in children, but common in adults. Empyemata containing staphylococci often indicate tuberculosis. An empyema complicating a case of pulmonary tuberculosis is generally pneumococcal or streptococcal. The naked-eye appearance of the pus is no reliable indication of the micro-organism. There is no essential bacteriological difference between serous and purulent effusions.

Mr. LOCKHART MUMMERY said that cases of empyema in children could be conveniently divided into two classes: (1) Those where the infection is purely pneumococcal, and (2) those where a mixed septic or tubercular infection exists. The great majority of cases are pneumococcal, and in these a free exit for the pus is all that is required, draining for any length of time is unnecessary, and it is often unnecessary to use a drainage tube at all. In the other class of cases and in those where much thickening of the pleura exists good drainage is always necessary. He advised irrigation of the pleural cavity with water of salt solution in suitable cases, and pointed out that the fatal results which have sometimes followed this practice are to be attributed to the iodine or carbolic acid solution used.

Dr. G. A. SUTHERLAND referred to the frequent absence and slight character of the symptoms in many cases of moderate pleural effusion. Breathlessness and tiredness on exertion were the commonest symptoms complained of. Coughing, pyrexia, wasting and anæmia were often present, but were not diagnostic. A lemon-coloured skin and clubbing of the fingers which had developed rapidly and without cyanosis, were strongly suggestive of purulent effusion. A diagnosis could only be made by a careful examination of the chest, noting the position and condition of the lungs, the heart, and the diaphragm as indicated by the stomach resonance and the hepatic dulness. The chief use of the exploring needle was not to determine the presence of fluid, but to distinguish between serous and purulent effusion.

Dr. HOBHOUSE (Brighton) said there can be no doubt that we can cut short the acute pleurisy and prevent effusion by active measures in the early stage, but when once effusion has fairly commenced it is very doubtful whether it can be cut short by any medical measures. Two or three different lines of treatment have been pursued by different authorities. In the first instance it was sought to reduce the quantity of fluid by increasing the fluid output and reducing the intake. With this object, diuretics, diaphoretics and purgatives were given freely, and a thirst diet adopted; most authorities are agreed that the results attained are by no means proportionate to the discomfort entailed. If a reasonable trial of medical measures is insufficient to reduce the effusion, it will be necessary to remove the fluid by puncture.

Dr. W. J. S. BYTHELL said, about three years ago he was to undertake the investigation of the bacteriology of empyema in children, and the objects at which he aimed were to determine (1) the course of infection of the pleura; (2) the species of micro-organism; (3) the influence of the bacteriology upon the clinical features of the disease. In forty cases of empyema, children whose ages varied between

ten months and eleven years, of these twenty-seven were males and thirteen females, the source of infection in over 80 per cent. was undoubtedly an acute broncho-pneumonia, 10 per cent. an acute pneumococcic infection of a pre-existing pulmonary tuberculosis; in another case it followed upon a sarcoma of the lung. In six cases the empyema appeared to be "primary." The influence of age upon the species of bacteria is well known, and his results confirm fully the great relative frequency of pneumococcus, the actual percentage in his cases was 90 alone or with streptococcus.

Dr. EWART read the notes of a case under his care at the Belgrave Hospital of a boy, *æt.* 10½, treated by paracentesis by symphonage and the admission of air into the pleural cavity, with subsequent relapse of the effusion, which was treated by intra-pleural injections of adrenalin solution without paracentesis with rapid recovery.

Dr. L. S. DUDGEON said that during the last five years he had made many examinations of the fluid taken from the chest in cases of serous and purulent effusion, and he thought that since Widal originally suggested the method it was one of the most valuable we have, because if one drew off clear effusion and found the cells, either in few or large numbers consisting entirely of lymphocytes, he thought one could definitely say it was tuberculous. If, on the other hand, one found what was described as the polynuclear phagocyte one could say it was due to one of the pathogenic organisms. After a large experience during the last four or five years he had found it practically constantly. Another point to which reference was not made was that in one case he found a very large number of cells which showed active myototic figures, and when the child died it was found to suffer from diffuse sarcoma of the chest cavity and pleura.

Mr. ARTHUR EDMUNDS said he desired to exhibit an apparatus to demonstrate the importance, in relieving empyema, of making the opening into the chest sufficiently free, not only to allow of the pus being forced out voluntarily, but for other reasons. Although everyone has realised that the chest did fill in coughing and in violent expiration, he did not think it had been sufficiently realised that that method of expiratory filling of the affected lung was one which was constantly taking place. When the lung on the other side was connected with the affected one by a bronchus, and when the passage outwards was free, as in paralysis of the larynx, the movements of the chest wall would have no effect on the movements of the other side; alterations in the tracheal pressure were not able to affect that lung. But if there were an obstruction in the outflow from that tube, which took place by the movements of the vocal cords, then, on expiration, the unsupported lung where there was an opening into the chest wall would move also. That he believed took place not only in violent coughing, because he had shown by experiments on animals that after opening the chest wall and setting up an irritative reflex from the pleural cavity, the examination of the vocal cord was sufficient to cause blockage, so that while the lung on the sound side was collapsing, the lung on the other side was expanding. That was the process which he felt sure was going on during the whole course of healing of an empyema.

THE Royal College of Surgeons has issued the regulations relating to the Begley Studentship in Surgery and Anatomy. This studentship, which is of the value of £20 and tenable for three years, has been established by funds left for that purpose by the wife of the late Dr. William Chapman Begley as a tribute to his memory.

THE annual dinner of the West London Medico-Chirurgical Society will be held at the Wharnclyffe Rooms, Hotel Great Central, London, W., on Wednesday, February 7th, 1906. Tickets 7s. 6d. each (exclusive of wine) may be obtained of the Honorary Secretaries, Dr. Walter, Windmill Road, Romford; or Mr. E. P. Paton, M.S., Queen Anne Street, London, W.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

Paris, January 1st, 1906.

SALPINGITIS.

NOTHING seems easier than to distinguish a case of acute salpingitis. Nine times out of ten, at least, it can be said that every para-uterine tumefaction filling somewhat the vaginal *culs de sac* and accompanied by pain, tenderness to pressure, and inflammatory symptoms is a case of salpingitis. Although it can be either simple or bilateral, localised or complicated with certain inflammatory phenomena of the peritoneum, yet it is none the less salpingitis, as the principal seat of the morbid manifestations is in the Fallopian tubes.

Frequently, says Dr. Faure, it is not necessary, in order to affirm the reality of the infection of the tubes, that all the classical symptoms should be present. It is often impossible, for instance, if the patient has a certain embonpoint, to distinguish with precision and tumefaction in the *culs de sac*; but a certain degree of immobility of uterus, which seems fixed at both sides when touched by the finger, is frequently sufficient to clear up the diagnosis.

According to the virulence of the infection, salpingitis can present varied forms, from the simplest lesions, where only slight tenderness is complained of, to the formidable developments of peritoneal infection.

The treatment of acute salpingitis is simple enough. Rest in bed, the ice bag to the abdomen if pain is very great, hot injections, or, better still, hot enemas.

In the majority of cases the symptoms disappear under the treatment, and resolution is complete. But this happy termination is not the absolute rule. Sometimes in spite of the above treatment the infection makes headway, the general symptoms become aggravated, the fever rises, and the pain, an important point, becomes more intense and symptoms of general peritonitis are observed, and in such cases an operation can alone save the patient. Colpotomy is frequently sufficient, but vaginal hysterectomy is sometimes necessary.

Chronic salpingitis is more amenable to surgical than to medical treatment; yet medical treatment is more or less successful when the patient is sufficiently docile and can be persuaded to take prolonged rest. However, where the pain persists and the lesions become aggravated, the physician must give way to the surgeon.

TREATMENT OF PLEURITIC EFFUSION.

Of the different agents prescribed against effusion into the pleura, salicylate of soda has obtained the most favour. It is not necessary to administer it in very large doses, but if after three weeks' trial no benefit results, it should be dropped and thoracentesis practised.

Quite recently Schedel recommended for the same malady chloride of barium, given in one grain doses three times a day, and after him Pesci made a series of experiments on forty-three patients, in whom he remarked the extraordinary curative properties of chloride of barium. Under the influence of the diuretic provoked by this drug at the above doses, the pleuritic effusions disappeared in a few days.

This effect was constant and was witnessed even in the febrile period of the malady.

NOTE.—In last letter—subject, Locomotor Ataxy—Nitrate of soda should have been printed *nitrite* of soda.

Berlin, December 31st, 1905.

At the Verein für Innere Medizin, Hr. Rothmann showed a young woman, *æt.* 22, with

DOUBLE FACIAL PARALYSIS.

The patient had at an earlier period suffered from tuberculous disease of the bones of the right ear, on account of which a radical operation had been per-

formed in February last, from which right-sided facial paralysis had resulted. Besides this, there was contraction in the region supplied by the left facial, with paralysis of the left upper branches. Careful examination revealed loss of sensation of both corneæ and hysterical analgesia of the whole side of the body. The case was one therefore of organic facial paralysis of the one side and hysterical paralysis of the other.

At the Charité Society, Mr. Bum showed a

VAGINAL CÆSAREAN SECTION

on a woman who was extremely collapsed from mitral insufficiency and stenosis. After opening the anterior vaginal arch, turning and extraction of the foetus were easily accomplished. After the operation which lasted only a few minutes and by which a living child was extracted the patient recovered rapidly.

Hr. Liepmann showed preparations from

THREE CASES OF RUPTURE OF THE UTERUS,

One at the fundus, one at the contractile ring, and one a total colpo-pontrexia caused by incautious use of the forceps. In two of the cases life was saved after laparotomy.

At the Medical Society Hr. Rosenstein showed a series of drawings that he had taken of

TUBERCULOUS KIDNEYS

that had been removed by J. Israel. Three forms were distinguished (a) the ulcerated cavernous form; (b) tuberculous ulceration of the tips of papillæ, and (c) the chronic nodular form, all three of which could naturally be differentiated only in the commencing stages. Regarding the identification of the b form not only was exploratory opening up of the kidney necessary, but under certain circumstances even free incision into the pelvis of the kidney. He hoped that in the future by functional diagnosis chronic tuberculous disease of the kidney would be recognised so early that total extirpation of the organ would be no longer necessary, but that partial resection would be enough to bring about permanent recovery.

Hr. Dith pointed out that an early stage of tuberculosis of the kidney was often enough recognised *post mortem*, where no symptoms of the disease had been noticeable during life. The first commencement of the tuberculosis was found in the medulla or in the calices at the point where the mucous membrane surrounded the papillæ tips. The early appearance of the disease in the medulla was explained by the appearance of tubercle bacilli in the straight canaliculi; in the glomeruli the bacilli must be passed out from the blood in acute miliary tuberculosis.

Of great importance for the development of tuberculosis of the kidney was tubercle of the arterial walls. From blocking up the lumen of the vessel an infarct might form, which might become tuberculous later on, or tuberculosis of the whole area supplied by the artery might be set up. Tubercle bacilli had also been demonstrated in the canaliculi without the kidney itself becoming tuberculous. (Benda.)

At the Society for Innere Medizin, Hr. Gutzmann showed a boy, æt. 12, who was sent to him on account of

DEFECTIVE ARTICULATION.

In looking at the boy's face it was seen that the whole skin of the face was affected by a sort of pasty swelling, the lips especially were very much swollen. Along with this there was complete absence of expression in consequence of immobility of the facial musculature, so that the forehead could not be wrinkled, and instead of laughing, the boy only succeeded in drawing the mouth slightly outwards. At a first glance myxœdema might be diagnosed, but a more careful examination showed complete diplegia of the abdomen. There were other malformations also—the left hand was smaller than the right, and there was a web between the second and third fingers. There was almost complete aphasia of the mammary glands and pesse quinus of both sides. The muscles of the trunk were otherwise normal. From photographs taken in early life it was seen that the disease had not progressed. The defective power of articulation was caused by the immobility of the swollen lips. The speaker was attempting to

improve the articulation by tongue exercises as a substitute for the defective lip movements.

Hr. Rothmann asked if thyroid preparations had been tried. The swelling of the face was so great that there might perhaps be myxœdema along with the diplegia of the facial.

Hr. Gutzmann replied that the thyroid was present, and the mental condition was normal, and that was against any assumption of myxœdema. The boy was very good at figures and was quite intelligent.

Hr. Goldscheider asked if the boy perspired? He asked the question because Gutzmann had said that the boy showed aphasia of the mammæ, and he himself had seen such a case in which the sweat glands were absent.

Hr. Gutzmann replied that the boy did perspire. The aphasia was not complete, the nipples were only indicated.

Vienna, December 31st, 1905.

JOSEF SKODA.

LAST week the two great medical societies, the Gesellschaft and the Doctoren Kollegium, celebrated the anniversary of Skoda's birthday. A large number of medical dignitaries and honourables were present to hear Hofrat Schrotter proclaim the greatness of Vienna's medical knowledge. In a spirited prolegomena, in which he regretfully spoke of the vacant chair of Nothnagel, he assured his audience that the medical teachings of the Austrian schools were never before in such a perfect condition as they were at the present time, for which they had to thank their ancestors for such a noble heritage. Skoda, like Rokitansky, was a foreigner, and not an Austrian, but he had, along with Rokitansky, raised the Vienna School to a very high pedestal in European medicine. Lænnec first introduced the stethoscope, but Skoda taught us how to use it, and profit by its results. His labour differentiated a number of thoracic diseases that formerly were classed as one. What Skoda commenced in auscultation and percussion Rokitansky confirmed in the *post mortem* room, with the pathological specimen. He was theoretical and practical, always ready to investigate the origin, as well as the result, and to his present knowledge of disease Vienna owes its present splendid supply of water.

He was born in Pilsner, Bohemia, 1803, the son of a locksmith in indigent circumstances. After qualifying at Vienna, he returned to his native land to practise when an epidemic of cholera swept over Europe. Subsequently he returned to Vienna, where he joined Rokitansky in all his great work. Here Schrötter related his own impressions of the "great teacher." In his farewell lecture he told them (in 1870) that he was leaving, but the microscope and chemist were coming to take his place. He died on June 13th 1881, leaving behind him a protocol to be read by every medical scientist as the real basis of our present knowledge.

SPIROCHÆTA PALLIDA.

A great fight still rages round the spirochæta in syphilis, some have it in the secretions, while others cannot find it; others affirm this is the casual germ, and by another section it is denied.

Lipschütz affirms after careful examination that he has found the spirochæta pallida in both primary and secondary syphilis, as well as in congenital syphilis. These germs are to be found in the inter cellular tissues in large quantities, as well as in the morbid products of the disease. He has injected these products into monkeys and obtained the same result—spirochæta pallida. When non-syphilitic tissues were used or secretions were used the results were negative.

IODINE AS AN ORAL POISON.

Witzel declaims against the use of iodine for painting the gums, as frequently performed in dentistry. For proof of this testimony, he relates the history of a patient who had the gums painted six times with the tincture for pain, followed by a large inflammatory abscess in the roof of the mouth which had to be incised and carefully dressed. He thinks dentists should be

warned against this savage practice of painting the gums with iodine.

Budapest, December 30th, 1905.

In the "Gyogjaszat," T. Osin publishes an article on the

STERILISATION OF SURGICAL SILK BY DIFFUSION CURRENTS.

It has been admitted that although water and alcohol have no disinfecting power alone, when one is added to an article impregnated with the other, the diffusion causes currents in and around the bacteria, which kill staphylococci in two minutes. The author has applied this principle to the sterilisation of surgeon's silk. This is first boiled in alcohol, to remove all fat, impurities, &c. It is then set aside to dry, and before an operation it is boiled in water for twenty minutes, then placed for five minutes in alcohol, then for five minutes in water, and again in alcohol for twenty minutes. He has used this silk extensively, and has not had a single case of stitch where it was employed.

Dr. Manszler writes on the DIFFICULTIES OF EARLY DIAGNOSIS OF PERITONITIS AFTER APPENDICITIS.

There is no symptom that will inform us absolutely of the advent of peritonitis after appendicitis. Fever may be altogether absent, while chills are rare. The pulse is extremely unreliable, as it may be normal with pus in the peritoneal cavity, and much increased without this. The facies constitute an important sign, but exceptions to the rule are frequent. A tendency to syncope and a change in voice have been mentioned, but are altogether too indefinite to decide so important a point. Of more importance are tympanites and inability to pass gas. The association of certain symptoms may be of some value. These are: changed facial expression, pains radiating towards navel, epigastrium or left, and persistent despite the application of ice; dyspnoea, restlessness, fall of temperature, and a tendency to syncope.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

NEW SURGICAL OUT-PATIENT DEPARTMENT, EDINBURGH ROYAL INFIRMARY.—This new department, which has for several months been under construction, was formally opened by Lady Cranston on December 22nd. In 1903 the proposal to reconstruct the surgical out-patient rooms, so as to render them adequate for the treatment of the 15,000 cases which the Infirmary has to deal with annually, was first mooted, and a committee of the managers was appointed to inquire into what was being done in other large hospitals. The immediate cause of action being taken in the matter was the occurrence of so-called "scandals"—patients being brought to the Infirmary to receive treatment for accidental injuries, and being kept waiting, unattended to, for considerable periods. Inquiry into these unfortunate occurrences fully absolved the hospital staff from blame; it was shown that the system, not the officials, was at fault, hence the resolve to tackle the matter from its foundation, and erect a new department, which will be commensurate with the work for many years to come. The new department is situated in the same part of the hospital as formerly—that is in the lower storey of the north-east pavilion, and in the adjacent ground. Facing the entrance hall is a waiting-room, from which a corridor leads to four pairs of spacious dressing-rooms. One pair of (male and female) dressing-rooms is for fractures, another for septic cases, another for "clean" cases, and the fourth is set apart for the women students. The whole is fitted up in the most approved style—tiled walls and ceilings, terrazzo floors, sterilizing appliances, etc. Beyond the dressing-rooms there is a room for the surgeon-in-charge, for the sister, and for the resident sur-

geons. From the waiting-room a glass corridor gives access to a newly erected operating theatre, accommodating about 100 students, to which four ante-rooms for anaesthesia, etc., are attached. Adjacent to the new department a casualty ward has been opened, into which patients brought into hospital unconscious may be admitted until such time as a definite diagnosis is arrived at. The arrangements for the working of the out-patient department have also been completely changed to suit the new premises. The surgical out-patients will now be under the charge of one assistant-surgeon, who is to act for four months, and during that period will be relieved of his other duties. Under him there are to be three house-surgeons, each of whom will be on duty for eight hours of the day. The nursing staff consists of a sister, with four nurses, one of whom will always be on duty. The managers of the Infirmary have also introduced another reform, which, though of minor importance, will greatly enhance the convenience of the staff, and will benefit the patients in the wards. The existing telephonic arrangements have been replaced by an exchange in the Infirmary, managed by the National Telephone Company, one of whose operators will be constantly on duty. It will now be possible for any of the staff to call up his wards directly without the delay incidental to the previous system of a private independent telephone system in the hospital.

CITY OF EDINBURGH AND THE BACTERIOLOGICAL EXAMINATION OF SPECIMENS.—Some years ago the municipality withdrew the work of reporting on sputum, etc., in cases of suspected infectious disease from the Laboratory of the Royal College of Physicians, and gave it to the then newly-opened Usher Institute. Most of the medical men in the town resented this act in some measure, because the College Laboratory, which had, on its own initiative done the work gratuitously ever since its foundation, was felt to have earned the right, now that the city had realised its duties, to some financial aid. And, as a matter of fact, for a few years prior to the opening of the Usher Institute, the town had made an arrangement with the College to pay for specimens examined—an arrangement which was later abrogated in favour of the Usher Institute, though by a very small majority, the voting being 21 to 20. Since this time the two institutions have been doing reporting work, the College Laboratory gratuitously, the Usher Institute in return for payment by the town. At the last meeting of the Town Council Dr. Cullen moved that without altering the arrangement with the Usher Institute the town should again pay the College Laboratory a fixed sum for every specimen examined. A long discussion took place, but eventually it was decided by a majority of 25 votes to 15 to maintain the *status quo*. It is said that there is a certain amount of prejudice among the practitioners of Edinburgh against the Usher Institute. That, even if this ever existed, it is being borne down now, is shown by the fact that the specimens sent have risen from 880 in 1904 to 1,300 this year. The real explanation is that medical men were perfectly satisfied with the work done by the College Laboratory, and felt it had at the time been hardly treated. But, after all, reporting work of this kind, important though it be, is largely routine, and many now think that, seeing that bacteriological work is being done by the town, the Laboratory of the College might restrict itself to the higher work of research, for which it is so well equipped. At least, it is to be hoped that Town Councillors will have no more opportunities afforded them of talking about the "trade unionism" of the College of Physicians.

LORD ROTHSCHILD has accepted the office of president, and Sir Frederick Treves that of consulting surgeon to the Royal Dental Hospital of London, Leicester Square.

SIR WILLIAM FOSTER was last week appointed to the distinguished position of Membership of the King's Privy Council.

LETTERS TO THE EDITOR.

HOSPITAL AMALGAMATION AND THE SCOTCH AND IRISH DIPLOMATES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—In a recent valuable leader dealing with the King Edward's Hospital Fund, you touch upon their policy of pressing forward amalgamation of the smaller hospitals. You also advert to the fact that in case of such a step the question of the unjust exclusion of Scotch and Irish qualifications by certain hospitals must be considered. The matter was forced into the field of practical politics by the proposal to amalgamate the London Orthopædic Hospitals. One of the most distinguished surgeons at the Royal Orthopædic Hospital was F.R.C.S. of Edinburgh. The Royal Orthopædic Hospital rejoices in the unjust condition of staff appointment which says that no Scotch or Irish need apply. The compact was carried out between the National and the Royal that every surgeon must have the Fellowship of the English College.

Then pressure was brought upon the City Orthopædic Hospital to join the amalgamation. There are two distinguished surgeons on the staff of that institution, and it was presumably intended to oust them also from their positions on the score of the insufficiency of the Scotch Fellowship. Now that the City Orthopædic has consented to join the scheme, it may be presumed that this abominable restriction has been removed. Anyway, the eyes of King Edward's Fund have been opened as to what injury their amalgamation policy may cause to honourable and blameless men, merely at the instigation of the worst kind of trades unionism. Thanks to your outspoken articles of a year or more ago, the risk of removing that iniquitous restriction from the staff appointments of the London hospitals has been initiated. In my opinion you deserve the gratitude of every Scotch and Irish graduate and diplomat.

Much remains to be done. You have inserted the thin end of the wedge in courageous fashion. The campaign will be carried on, I am glad to learn, by the Irish Graduates' Association, and the newly-formed and energetic Association of Medical Diplomates of Scotland. There can be no stay or compromise in the matter. What we demand is absolute equality and freedom of competition for hospital appointments all over the United Kingdom.

Individually I am glad to believe that the many London surgeons and physicians of London hospitals whom I am proud to reckon among my friends are incapable of any mean or unjust act. But, collectively, none the less, they are helping to maintain a sordid and grossly selfish system, whereby they are unfairly put in possession of a valuable monopoly.

Trusting you will find space for this somewhat long letter, I enclose my card.

I remain, sir, yours truly,
F.R.C.S.I. & F.R.C.S.Ed.

Harley Street, London, W., Dec. 30th, 1905.

THE PROPOSED APOTHECARIES' "HALL" ASSISTANTS' ASSOCIATION: AN APPEAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With the aid of some of my colleagues in the Public Service I am desirous of forming an association of holders of the assistants' certificate of the Society of Apothecaries of London.

I, therefore, beg to ask you to be good enough to give me your valuable assistance by allowing me to make an appeal in your columns to all who may be interested in the matter, especially to those holding appointments in the public and hospital services.

Several of us have felt for some time past that our interests are greatly imperilled through lack of organisation. We feel that the time is ripe to combine to enable us to protect the undoubted privileges and advantages which we possess.

I may say that I have had a personal interview with

Mr. A. M. Upton, clerk to the Society of Apothecaries, who assured me of the sympathy and support of that body. He also promised a very substantial aid by offering, subject to the approval of the Master and Wardens, to place a room at the Society's hall at our disposal in which to meet and discuss the several questions which are now agitating the whole dispensing body.

I therefore earnestly invite all those who may be willing to join such an association to forward to me their names and addresses at their earliest convenience. Should this appeal meet with a satisfactory response I will at once take steps to call a meeting.

I am, Sir, yours truly,

ALBERT HOWELL.

Hackney Union Dispensary, Dalston, N.E.

REVIEWS OF BOOKS.

ROSE AND CARLESS' SURGERY.*

PROFESSOR HUXLEY used to maintain that only the greatest masters of an art were competent to write an elementary text-book on it; and what an elementary text-book should be, he himself showed by his small "Physiology," which saw the light some thirty-five years ago, and (like Charley's Aunt) is still running. The writers of a text-book on surgery, then, who find their work in the sixth edition seven years after publication, may take to themselves the reflection that they have acquired a mastery of their art which has emerged triumphant from the most exacting of ordeals. The student on the whole is a conservative animal, and, not without reason, he clings to the old favourites among his text-books till he sees good reasons for acquiring new friends. But such a new friend he has found in "Rose and Carless," and it is certain that this friend has come to stay. It is not difficult to find in this treatise on Surgery the elements that have already made it an established success, for it responds readily to all the tests that a good student's text-book should be proved by. In the first place, it is scrupulously accurate. If it is didactic, that, it may be answered, is of the essence of its nature, and does not impair its accuracy. Secondly, it is lucid. This is high praise for a volume on so extensive a subject as surgery, which must be kept within the bounds appropriate to a manual. The difficulty of preserving lucidity in short essays on the complex problems of surgical diseases is one that can only be appreciated by those who have tried, and "Rose and Carless" has the high merit of never allowing the subject to master the pen, nor of leading its readers into quagmires of ambiguity when they are seeking clear, succinct, and definite teaching. Thirdly, it has interest. A text-book of abbreviated form is apt to degenerate into a catalogue of symptoms, theories, and procedures, and only enthusiasts with a touch of inspiration are capable of turning out a manual of surgery which is also a human document. Again, within their severe limits, the authors have succeeded in performing a feat of no little agility, and one which redounds to the credit of their heart no less than to that of their head. We have spoken so far of "Rose and Carless," for the book appears under the joint authorship of those surgeons, and under those names it has become as familiar in the mouth of the latter-day generation of students and young practitioners as household words. But we notice with regret that Mr. Rose has dropped out of responsibility for the present edition, and that Mr. Carless has had the whole work on his shoulders. In order to ensure the accuracy of the sections on "Bacteriology" and "The Blood in Health and Disease," he has secured the co-operation of Dr. D'Este Emery, Clinical Pathologist to King's College

* "A Manual of Surgery for Students and Practitioners." By William Rose, M.B., B.S., F.R.C.S., Emeritus Professor of Surgery in King's College, London, and Albert Carless, M.S., F.R.C.S., Professor of Surgery in King's College, London. Sixth Edition. University Series. London: Baillière, Tindall and Cox. 36 Plates and 500 Illustrations. 21s. net, cloth, and 25s. net, flexible leather, gilt.

Hospital, and this gentleman has also revised the work from the standpoint of the latest pathological teaching. Help, too, has been obtained from Mr. Reid, Radiographer to King's College Hospital, who has lent his experience in the composition of the chapters which deal with radiography and light treatment. While we find ourselves able warmly to commend the book as a whole, there are certain points naturally which lend themselves to criticism. We would draw attention to the surprising statement on page 1094—that in hernia (under certain circumstances) "taxis is objectionable, and, if employed at all, should be used in the most perfunctory fashion." We quite agree that taxis is objectionable under the conditions noted, but surely the authors do not mean that it is safe to employ it "in the most perfunctory fashion." In the chapter on prostatic enlargement, it is noticeable that the authors agree with Mr. Freyer in claiming that total prostatectomy not only is possible, but that it is the operation that is to be aimed at. It is, perhaps, still permissible for surgeons to hold differing views on this subject, but it is not quite consistent to state (page 1218) that "either procedure" (for enucleating the prostate) "is possible, and in the more exaggerated cases there is not much to choose between them," and (page 1219), "One fallacy must be avoided," namely, "Opening up a line of cleavage which runs inside the capsule between it and the adenomatous masses." Nor do we think it is adequately explained that the "capsule" in adenoma of the prostate represents the remains of the gland, thinned out, and atrophied. We note also that it is recommended that prostatic abscesses, acute and chronic, should be opened through the perinaeum, the choice of the rectal route not being given, even when pus happens to point there. These, and a few other points that might be mentioned, do not seriously impair this manual; it is a fine performance, admirably and skillfully carried out; and endows the "University Series" with a lustre equal to that of any of its companions. The publishers have been particularly happy in the selection of a type and a paper which make the book most pleasant to read, although it comprises no less than 1350 pages and is easily held in the hand.

LITERARY NOTES.

AN interesting medico-sociological study on "The Alcohol Problem in its Biological Aspect," by Dr. T. N. Kelynack, Honorary Secretary of the Society for the Study of Inebriety, is now in the press, and will be issued immediately.

READERS of that exquisite short story, "Rab and his Friends," will be glad to know that a volume of letters by its author the late Dr. John Brown, of Edinburgh, is in preparation. Few men understood child-life more perfectly, or ever gave the world a more touching study of the devotion of a shepherd's dog.

THE forthcoming number of *The British Journal of Inebriety* will contain a full report of Professor D. Crothers' "Norman Kerr Memorial Lecture," an abstract of which recently appeared in our columns.

AMONG the many changes in business methods as they affect medical men may be mentioned the enterprise of some of the leading manufacturing druggists. We have before us "The Consultant's Appointment Book," of Messrs. Burroughs, Wellcome and Co., and the handy "Note-Book" of Messrs. Scott and Bowne, both handsomely turned out, and each is, we understand, sent gratuitously to every registered practitioner in the United Kingdom. Beside the daily usefulness of these pocket remembrancers, there is an insurance coupon enclosed in "The Note Book," by which the representatives of any medical man meeting his death by accident during the year can claim £500 or £250 as the case may be, without cost of insurance policy or premium.

OBITUARY.

ROBERT TIMOTHY MATTERSON, L.R.C.S.ED., M.R.C.S.ENG.

THE death took place recently at Langenhoe Rectory, Essex, of Mr. Robert Timothy Matterson, formerly of Newark. The deceased gentleman, who was in his seventy-eighth year, was in practice at Newark for the long period of forty-two years—from 1862 to 1904. He studied at Leeds and St. Bartholomew's Hospital, and took the diploma of L.R.C.P. of Edinburgh, and that of M.R.C.S. of England in 1860. For a short period afterwards he filled the post of house physician of the Leeds Infirmary, and then proceeded to Newark. There in time he became the senior hon. house surgeon of the Newark Hospital, the public vaccination officer of the Newark district of the Newark Union, and the medical officer of the Newark School Board.

THOMAS CHARLES LANGDON, F.R.C.S., OF WINCHESTER.

By the recent death of Mr. Thomas Charles Langdon, Winchester has lost a prominent citizen, and the medical profession an honourable and accomplished member. He was born at Baampton, in 1835, and was therefore 70 years of age at the time of his death. He was educated at St. Bartholomew's Hospital, whence he took the M.R.C.S. England in 1858, and the Fellowship in 1862. His first connection with Winchester was in 1860, when he was appointed House Surgeon to the County Hospital. He held many honorary and other appointments, but was best known as Medical Officer of Health of the City, to which he was elected on July 24th, 1873. He filled that post for 32 years, truly a remarkable record of service. He leaves a widow and a large family to mourn his loss, as well as a large circle of friends.

JAMES HENRY CEELY, F.R.C.S. ENGLAND.

WE regret to announce the death of Mr. James Henry Ceely, F.R.C.S., on Christmas Day, at his residence in Tregunter Road, London, S.W., aged 96. Mr. Ceely, who had retired from practice, studied at the London Hospital, and was qualified in 1830, when he obtained the licence of the Society of Apothecaries. In 1832 he obtained the membership of the College of Surgeons of England, and 20 years later he was elected Fellow. He was formerly surgeon of Aylesbury Prison, senior surgeon of the Bucks General Infirmary, and surgeon-in-chief of the Bucks County Constabulary.

WILLIAM ARTHUR PAYNE, M.A., M.B. OXON., M.R.C.S.ENG., L.S.A.

WE regret to record the death of Dr. Arthur Payne, of Barford, Warwickshire. His medical education was conducted at St. Bartholomew's, whence he took the L.S.A. in 1886, M.R.C.S. Eng. in 1887, and M.B. Oxon. in 1893. Dr. Payne had only resided in Barford two and a half years, previous to which he practised in Ilfracombe, but the term had been long enough for him to have found a way into the hearts of the people. He was everywhere deeply honoured and esteemed as a man and fully trusted as a medical attendant. It appears that about ten days before his death Dr. Payne spent five hours one night with a delirious patient, who was suffering from septic pneumonia, in a small ill-ventilated cottage, and thereby no doubt contracted the fatal illness which carried him off.

THOMAS ALBERT CARTER, M.D. EDIN., F.R.C.P. LOND., J.P.

WE regret to announce the death of Dr. T. A. Carter, at his residence, Shottery Hill, Stratford-on-Avon, at the advanced age of 71. Dr. Carter was formerly in practice at Leamington, and came to Shottery Hall about seventeen years ago. He was medically educated at Edinburgh University, where he graduated M.D., with honours in 1856.

MEDICAL NEWS IN BRIEF.

Health of the Navy.

THE report on the health of the Navy for 1904, which was issued on Saturday last, shows generally a very satisfactory condition, there being a decrease in sickness compared with the reports of each year since 1897. Out of 110,570 men afloat, which is an increase of over 7,000, the daily rate of sick was 31.35 per 1,000. The deaths per 1,000 numbered 4.45, and invalidings totalled 2,511, the decrease being considerable in each case. The most unhealthy stations were the Pacific and East Indies. Tuberculous diseases formed by far the largest proportion of the invaliding cases, whilst diseases of the digestive tract were responsible for many thousands of others. Nervous diseases were the next highest. Mediterranean fever is specially dealt with in the report by Fleet-Surgeon P. W. Bassett-Smith, Staff-Surgeon E. A. Shaw, Fleet-Surgeon D. J. McNabb, and Fleet-Surgeon R. T. Gilmour. The report is signed by Inspector-General H. M. Ellis, Medical Director-General of the Navy.

The "Strike of Doctors" at Exeter Dispensary.

AFTER prolonged, and at times bitter, controversy the Exeter Dispensary dispute has been settled in a way most satisfactory to Englishmen—namely, by a compromise. The history of the affair is both interesting and instructive. The history is as follows—the medical staff of the Dispensary recommended the installation of an X-ray apparatus. In order to lessen the cost they advised that the apparatus should be available for persons not patients at the institution, fees thus obtained to be divided between medical attendants and Dispensary. The Committee took up the position that the staff wished to put the institution to the cost of an installation in order that they might make fees by using it for their private patients. The staff thereupon resigned in a body. The lay press has widely commented on what they choose to call the "strike of doctors," but the matter is now happily settled, and the medical staff have consented to retain their position.

Boric Acid in Sausages. Important Case—Conviction.

ON the 19th ult. at Worship Street Police-Court, London, Mr. Cluer gave judgment in the case of defendants Messrs. W. E. and C. C. Patterson, provision dealers, of Cambridge Road, London, E. The prosecutors were the Borough Council of Bethnal Green. The specific charge was the sale to the prejudice of the purchaser of a certain article of food—sausages—which contained 41 grains of boric acid per pound. The defence pleaded that boric acid was not prejudicial to health and that there was no standard for sausages. The analyst spoke of boric acid as a "foreign ingredient," but admitted that one tenth of foreign sausages imported contained boric acid, and also three fourths of the imported butter. The magistrate remarked he had to administer an Act. After an exhaustive trial, extending over two days, the defendants were convicted of the offence. In giving judgment, the magistrate said he could come to no other conclusion than that one article was asked for, and something which contained a foreign ingredient supplied. He had no doubt the case would be taken elsewhere, and he was glad to think it would be. He imposed a nominal fine of 20s., and ordered the defendants to pay also seven guineas costs.

Dispute between the Wrexham Town Council and the Local Government Board.

FOR several months the question of the appointment of a medical officer of health for Wrexham has been under the consideration of the Town Council. The Local Government Board suggested that the Council should join the Rural District Council in the appointment of a single "whole time" officer for the urban and rural districts. The rural District Council were prepared to fall in with this suggestion, but there is a division of opinion among the members of the Town

Council, and after many debates it was decided at a recent meeting by a narrow majority to appoint a medical officer for the borough alone. In response to this notification the Local Government Board wrote asking the Council to reconsider the matter, but it was replied that the Council saw no reason to alter their decision. Again the board wrote, expressing a hope that the Council would give further consideration to their suggestion, and this letter was discussed at a meeting of the Town Council on Wednesday. After some further discussion the letter was referred to the Sanitary Committee for consideration. The attention recently given to the tenure of rural medical officership and the advent of a new Government renders the situation at Wrexham particularly interesting.

Boots' Stores and Ammoniated Quinine.—Abortive Liverpool Prosecution.

ON the 20th ult., at Liverpool City Police Court, before the stipendiary magistrate, Boots', Cash Chemists, Limited, were summoned on an information laid by the health authorities, which alleged that they sold "to an inspector at 203, Scotland Road, Liverpool, to the prejudice of the purchaser, a certain drug, to wit capsules of ammoniated quinine, not of the nature, substance, and quality demanded, the same not containing any ammonia, and the average amount of quinine sulphate in each capsule being only two-thirds of a grain, contrary to the statute." Mr. Duder, for the prosecution, said the city analyst's certificate stated that the sample he received contained no ammonia, and that the average amount of quinine sulphate in each capsule was only two-thirds of a grain. The Somerset House certificate said: "The capsules contain a small quantity of ammonia; the amount, however, is only nominal, the average weight of ammonia per capsule being—Ammonia: Free, practically 1-300th part of a grain." "Ammonia combined" worked out at 1-50th part of a grain. He was instructed that "combined ammonia" in these capsules was absolutely useless for medicinal purposes; it was only the free ammonia when present in sufficiently large amounts which could be of any use at all. With regard to the quinine, the Somerset House analysis showed that one capsule contained 1.19 grains, and, according to the British Pharmacopœia, it was only necessary to have 1.09. The magistrate, alluding to the difference between some of the capsules, said this was an accidental and not wilful circumstance, which the defendants would take some means to obviate. Mr. Glynn Jones, for the defence, said it was not possible to get mathematical accuracy as between the capsules. The magistrate did not think the case for the prosecution was made out, and it would therefore be dismissed. No order was made as to general costs.

Sale of Poisons. A Chemist may Sell Veratrine to "The Man in the Street."

IN the King's Bench Division, on the 9th ult., the Lord Chief Justice and Justices Lawrence and Ridley, heard the appeal of Edward Oliver Brown, of Leeds, against a conviction by the Leeds Stipendiary Magistrate, for unlawfully selling a certain scheduled poisonous vegetable alkaloid,—to wit, veratrine, to a person unknown to him, and not being then introduced by some person known to him. The magistrate stated a special case for the opinion of the High Court. The appellant was a registered chemist and druggist, and sold a packet of ointment for destroying vermin on the head. Counsel for the respondent contended that as the ointment contained a dangerous quantity of poisonous vegetable alkaloids included in Part. I. of the schedule, the defendant was guilty of the offence charged in the information. The Lord Chief Justice said that the fact that a poison named in the first part of the schedule was mixed with another ingredient did not make it less the sale of a poison. But the general idea of the Act was that the Pharmaceutical Society should have

power to say which things should be deemed to be poisons within Part I. of the schedule or Part II. They had made an order, the effect of which he held was that the substance sold by the appellant was put in Part II. That order, he was of opinion, the Pharmaceutical Society had power to make, and therefore the sale of this article was not the sale of a poison in Part I. of Schedule (a), which required it to be sold only to a person known to him. For these reasons the appeal must be allowed. The other Judges concurred, and the appeal was allowed, with costs.

Municipal Milk for Lambeth.

THE depot recently fitted up by the Lambeth Borough Council in London, at a cost of £500, for the sale of specially prepared milk for infants will be opened shortly, under the supervision of Dr. J. Priestley, the medical officer of health, who may be congratulated on having brought his district up-to-date in this most important matter. For the supply of milk a farm has been selected in Hampshire, which will be under medical and veterinary inspection, and the milk is guaranteed to be up to Government standard with fifty per cent. of butter fat. The quantities of the milk mixture to be given vary according to the age of the infant from 1½ oz. to 42 oz. per day. It will be distributed on the familiar plan in hermetically sealed bottles in wire baskets, each bottle containing sufficient milk for one meal and each basket a day's supply. For the full supply of milk 1s. 6d. per week will be charged for infants under six months old, and 2s. per week for infants aged from six to twelve months. The cost of maintenance will be about £500 a year, and the returns are expected to average £300. Dr. Priestley says that every year 1,400 children die in Lambeth before they are a year old, and that if some of these lives can be saved the loss of £200 on the depot will be more than balanced.

The Plague.

THE following telegram from Sir C. Boyle, Governor of Mauritius, was received at the Colonial Office, on December 15th:—Eight cases of plague reported during week ended yesterday. Number of deaths seven.

PASS LISTS.

University of London.

THE following passed the M.D. Examination during December:—

Medicine.—James Alfred Butler B.S. Guy's Hospital; Harold Benjamin Day, B.S., King's College (obtained the number of marks qualifying for the University Medal); Alfred Henry Gerrard (University Medal) University College and Guy's Hospital; George Hall, University College; George Johnson Langley, B.S., St. Thomas's Hospital; Edward Lister Martin, B.S., St. Bartholomew's Hospital; Ernst George Pringle, St. Bartholomew's Hospital (obtained the number of marks qualifying for the University Medal); Gwynne E. Owen Williams, B.S., University College.

Pathology.—Charles Edward Ham, London Hospital.

Mental Diseases and Psychology.—Margaret Bernard Dobson, Lond. R.F.H. Sch. of Med. for Women; Charles Arthur Mercier (University Medal), London Hospital.

Midwifery and Diseases of Women.—Olive Claydon, Lond. (R.F.H.) Sch. of Med. for Women; Mary Gertrude Edis, B.S., Lond. (R.F.H.) Sch. of Med. for Women; David Ellis, B.S., London Hospital; Archibald Montague Henry Gray, B.S. (University Medal), University College; Anthony Richard Nelgan, St. Bartholomew's Hospital; Neville Ivens Spriggs, Guy's Hospital.

The following passed the M.S. Examination:—

Janet Mary Campbell, M.D., Lond. (R.F.H.) Sch. of Med. for Women; Robert Valentine Dolbey, London Hospital (obtained the number of marks qualifying for the University Medal); Ernest W. H. Groves M.D., Bs.Sc. (University Medal), St. Bartholomew's Hospital; Alexander Moxon Webber, Guy's Hospital.

SPECIAL ARTICLE

THE RISKS OF LUNACY CERTIFICATION.

EVERY now and then our profession receives an unpleasant reminder of its risks and responsibilities, and such an one has just been furnished by the recent action brought against Drs. Carswell and Marion Gilchrist in the Court of Session. The purely medical aspects of the case are of no special interest. The pursuer, now happily recovered, was for a time insane, was certified as a lunatic, was consigned to Gartnavel Asylum, and was there cured. Instead of showing gratitude for his restoration to health, he sued those who had put him in the way of recovery for substantial damages, and though his claim was rejected by the Court, Dr. Gilchrist and Dr. Carswell were put to all the expense and anxiety inseparable from a long proof, and were exposed to the uncertainty as to whether law and medicine would for once agree on what constitutes insanity. "When the Devil was sick, the Devil a monk would be; When the Devil was well, the devil a monk was he." Surely the writer of the old saw had such cases as this in his mind!

Every profession must take certain risks, and the prudent man does not blink these, but, foreseeing, tries to anticipate and nullify them. We must take it that when a lunacy certificate is signed and put into effect the granter is exposed (particularly if the document fulfil its prime object, and the machinery it sets in motion lead to the patient's recovery) to an action for damages for incarceration in any asylum. That such an action is very seldom successful by no means robs it of its terrors, for too often the pursuer, giving him all credit for good faith, proves a man of straw, in which case the adage of sport is reversed, and "the winner pays."

Remembering the axiom that a man cannot contract himself out of his common law liabilities, it will be seen that no form of indemnity given beforehand by the patient or his friends can be of the slightest use in barring such an action; contrariwise, to demand any undertaking of the kind would rather suggest that the granter of the certificate had his own doubts as to the propriety of giving it. The risk should be met, as so many other risks are, by insurance, and this is best effected by membership of a thoroughly well established medical defence association, which is known to have funds ample to fight any cause. Keeping in view the need for insurance, it is a further question whether the ordinary guinea fee, scarcely adequate to repay the time and skill required to fill up a lunacy certificate, should not be raised.

As we read the daily proceedings in the action which forms the text of this note—its cloud of witnesses, and legal acumen, *not* lightning darkness—we wondered whether it were all too Utopian to dream of a changed procedure. The Scotch statute provides that such actions be tried by an Outer House Judge, without a jury, thus showing that our law-makers recognize that these cases have something special about them. Could not the procedure be still further simplified? A legal assessor, a medical assessor (Home Office officials, these); an overman, locally selected by the assessors, neither lawyer nor doctor; the Board, Commission, call it what you will, to have power to call for documents, declarations on oath, and witnesses if need be; the parties to be represented by agents, who should neither be allowed to cross-examine nor to address arguments to the Court, but only to speak on matters of fact—a commission such as we have sketched could settle nine-tenths, or ninety-nine-hundredths of all cases of this kind at a tithe of the cost and in a fraction of the time which a Court of Law requires. Nor would the liberty of the subject suffer any risk of infringement; by entering a Law Court, in which blind-folded Justice holds the scales so evenly balanced that litigants cross its threshold on even terms, he is at once divested to the detriment of his opponent of the burden of disproof which he bears.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for the MEDICAL PRESS AND CIRCULAR.

PARALYSIS AGITANS.

OPPENHEIM (*Deutsch Med. Woch.*, 1905) has recently in an able paper expressed his views as to the diagnosis and prognosis of this disease. He states that cases without tremor are not uncommon, and are frequently overlooked. In some instances the tremor is latent and may be elicited by active movements or by plunging the limb into cold water. He describes a procedure which produces what he calls a false ankleclonus. The foot is strongly flexed dorsally, and held in this position for some time; on release a rhythmical tremor may result, and is quite characteristic of paralysis agitans. In typical cases without tremor the diagnosis is made on the general attitude, the stiffness, and the propulsion and retropulsion. The cases most difficult of diagnosis are those in which the disease is just beginning, and only one side or limb is involved. He states as a general proposition that a slowly developing stiffness and unwilldiness in the limbs of one side occurring in an old individual is generally paralysis agitans. The slowing of movements and stiffness in these cases usually begin first at the distal parts of the extremities. In the fingers, difficulty in flexing or extending the fingers one after another may be noted early or abduction or adduction may be difficult. Changes in the toes are less easily detected, but Frank has described a valuable diagnostic sign. This consists in the fact that any attempt to move the toes on the affected side results in movements of the toes on the non-affected side; the reverse is not the case. In some cases changes in the handwriting are of value. The patients have a tendency to write slowly and construct much smaller letters than they formerly did. Various early or premonitory signs are mentioned, which may render diagnosis easier in doubtful cases. Rheumatoid pains, gastric disturbances, salivation, and hyperidrosis are mentioned as not infrequently preceding paralysis agitans or accompanying the early stages. Bladder and rectal disturbances are rare. In some instances the patient seems totally unable for some time to start walking even when he desires to pass merely from one room to another. He stands as if rooted to the spot, and appears quite helpless. Oppenheim thinks that in these instances there is a strong psychic element at work. As to prognosis, a more optimistic view is taken than formerly. The writer has never seen complete cure result, but he states that under proper conditions he has seen the progress of the disease apparently delayed for a considerable time, and he has seen severe cases transformed into mild ones. The prognosis is most favourable in those cases in which the condition is recognized early and the recognition of the atypical forms is necessary for this. D.

KERNIG'S SIGN.

ROGLET (*These de Paris*, September, 1905) gives the following explanation of Kernig's sign occurring in cerebro-spinal meningitis: When the thigh is flexed upon the trunk and the leg at the same time extended (Kernig's position) the sciatic nerve becomes stretched. In the healthy state, the stretching of the sciatic nerve seems not to produce any pathological response since Kernig's sign has never been clearly demonstrated in healthy individuals, except when the thigh is flexed upon the trunk at a very sharp angle, *i.e.*, when the sciatic nerve is greatly stretched. In morbid conditions where the nerve itself is affected (neuritis sciatica) or when the roots are affected, which undoubtedly takes place in acute meningitis, the stretched affected roots react correspondingly; the posterior roots by producing pain, and the motor roots by producing contractions of the corresponding muscles, in the case of the sciatic nerve the flexor muscles. The pain arising from the stretching of the posterior roots makes the patient instinctively keep away from

further stretching of the posterior roots, as it happens, for instance, in dislocations when the muscles respond with strong contraction to any active or passive movements in the dislocated joint. The above explanation may be held to be at least the simplest one we have for the understanding of the mechanism of Kernig's sign. The author concludes by stating that Kernig's sign may be considered as a standard sign of inflammatory meningeal lesions, and as being due to irritation of the spinal roots produced by the stretching of the sciatic nerve. D.

THE THYMUS.

MOORHEAD (*The Practitioner*, December, 1905) summarises our knowledge of the functions of this gland and gives an account of some experimental work which he himself has done in connection with it. Following Waldeyer, the histological history of the gland, is divided into three stages. The original hypoplastic diverticula arising from the third visceral arch hollow out, lose their connection with the pharynx, and, becoming free in the neck, bud off numerous solid epithelial outgrowths. This constitutes the epithelial stage, but from the outset lymph cells appear among the epithelial cells derived either by migration from the neighbouring mesoblast or from the ingrowing connective tissue. At birth, the gland is distinctly lobulated and encapsulated, each lobule presenting a cortical and medullary zone containing more or less lymphoid cells, and in the centre of the medullary zone one or more Hassal's corpuscles. The origin of these corpuscles is still disputed, some writers considering them the remnants of the epithelial buds, while others look on them as a proliferation of the endothelial lining of the blood vessels, Eosinophilous leucocytes are numerous along the fibrous septa, and some are usually found in the cortex of the gland. Moorhead has never found nucleated red blood corpuscles except in the vessels. The weight of the gland at birth varies so much that practically no information of value can be obtained from it except in extreme cases. In man the gland continues to grow both absolutely and relatively to the body weight up to the age of two years after which time the rate of growth diminishes till puberty when a gradual degeneration begins. In this, the third stage, the gland becomes infiltrated with fat, and there is a gradual increase of interstitial tissue. Experimental study of the function of the gland has not led to much result. As Moorhead says, his experiments have had purely negative results, or "seem to conclusively prove that the function of the gland is not directly to produce any influence on the vaso-motor system." Ghika believes that the different results arrived at by different observers depend on the difference in age of the animals experimented on, and that extracts of the gland have a distinctly favourable influence on the growth and nutrition of young animals. This belief is borne out by the beneficial results obtained by the therapeutic use of such extracts in the case of rickety and debilitated children. Temporary leucopænia with diminution of weight and arrest of development in animals have been found to follow the total extirpation of the gland, but these effects passed off in about two months' time. Such experiments, however, suggest some co-relation of function between the thymus and the generative organs. Moorhead's experiments with thymotoxic sera have convinced him that in extra-uterine life the importance of the thymus gland is not great. A study of the pathology of the gland has not proved its causal connection with any of the recognised diseases. K.

TREATMENT OF ADDISON'S DISEASE.

WEIGALL (*The Australasian Med. Gazette*, October, 1905) relates the case of a boy, æt. 18, whose father had

previously died of this disease, and who himself presented well-marked symptoms of it. The boy weighed 6 st. 4 lbs., pulse 140, and compressible, heart feeble, and respirations, when at rest, 30 per minute. The skin was generally pigmented, but there were patches of pigmentation particularly well-marked on the forehead. He complained of nothing but extreme fatigue. For the first few days he was treated by saline injections into the rectum, and by hypodermic injections of strychnine. The administration of extract of suprarenal capsule in the form of tablets was then begun. The actual dose is not stated, but at first one tablet was given three times a day, and soon this was increased to two, three times a day. The improvement is stated to have been extraordinary. In two weeks he had gained six pounds in weight, and his pulse had fallen to 110, and he was able to walk about the room without difficulty. The pigmentation had considerably diminished. The treatment was continued until he had taken 500 tablets. His weight is now 10 st. 8 lbs.; he is working all day on a farm, and feels perfectly well; the pigmentation has entirely disappeared. K,

TEAK DERMATITIS.

EVANS (*The British Journ. of Dermatology*, December, 1905) relates a case of a carpenter who, while working with teak, was attacked with a severe dermatitis. The attack began on the backs of his hands and spread to the forearms, chest, and face, later involving the entire trunk and lower limbs. At first there was mere redness of the skin, but soon it became moist and vesicular, and as the eruption was attended with severe itching there were numerous excoriations. The patient stated that ten years previously, while working with teak, he had a similar attack, and on account of the severity of that attack he had refused to work in teak until two days before the onset of his present illness. Of the eight men who were working with him six were attacked similarly, but in the others the attack was not so severe. There appears to be two varieties of teak wood, the softer and more superficial wood, which is harmless, and the harder or more central wood, which produces the irritation. This central wood contains the essential oil, none of which is found in the more superficial parts of the tree. Evans considers that this aromatic oil is the essential cause of the dermatitis, just as the dermatitis caused by the Rhus toxicodendron is really caused by the oily substance toxicodendrol, which can be obtained from the plant. Teak oil is said to be used medicinally in India, but whether its local application has caused dermatitis or not is not recorded. The only satisfactory way of preventing such attacks appears to be by completely avoiding the cause. K.

INFANTILE LOCOMOTOR ATAXIA.

To the previously recorded cases (*Deutsche Zeits. f. Nerven Heilkunde*, Bd. 26 3), 42 in number, of infantile or juvenile tabes and tabetic paralysis, Hagelstum adds three from Oppenheim's Klinikue. Out of the total of 45, 16 occurred in males and 29 in females; in six cases tabetic paralysis was present, and in the remainder tabes alone. In more than 25 per cent. of these cases paralysis or cerebral lesions were present in one or both parents. The writer considers that the condition is by no means rare, and that it may occur in children who are not congenital syphilitides, although syphilis acquired or congenital is, in a majority of cases, present. The condition usually shows itself first at puberty, and both motor and sensory symptoms may be slow in developing. Spinal arthropathies and visceral crises are often met with. M.

THE TREATMENT OF HODGKIN'S DISEASES BY X-RAYS.

Among the unfavourable effects caused by Röntgen-ray therapy in cases of pseudo-leukæmia Quadrone (*Centralbl. f. Inn. Med.*, 1905, No. 31) states that he has observed the occurrence of pleural effusion in two instances. The first case was that of a girl, æt. 12,

suffering from enlarged glands at the root of the right lung. After ten exposures there was a marked improvement in the subjective symptoms, and an apparent diminution in size of the glands, but at the same time there appeared suddenly an enormous right-sided pleural exudate. This was tapped on several occasions, but was succeeded by a left-sided effusion, and by death from asystole. The second case was that of a man, æt. 28, with large lymphomata in the left cervical, supra-clavicular, and axillary regions. After thirty exposures the glands were decidedly smaller, but there appeared all the symptoms of gastro-intestinal intoxication. These symptoms subsided after a time, but on resumption of the treatment an extensive left pleural effusion appeared, which, however, completely disappeared after tapping. From the clinical characters of these cases the author is of opinion that the pleural affection was in both of these directly connected with the X-ray treatment. M.

DEATH FOLLOWING SCOPOLAMINE MORPHINE INJECTIONS.

DR. SEXTON (*Lancet Clinic*, U.S.A., November 18th, 1905) reports an important case of death following an injection of scopolamine and morphine, administered for anæsthetic purposes. The patient was a woman, æt. 47, who had suffered during the last five years from menorrhagia, due to the presence of a uterine fibroid. The excessive hæmorrhage had produced severe anæmia and general malnutrition. An operation was decided upon, and the patient was admitted into hospital and placed under tonic treatment for a time. At 7.30 a.m. on the morning of operation, an injection of scopolamine hydrobromate, 1-100th grain, and morphine sulphate 1/4th grain, was given, and caused sleep in a few minutes. At 8 a.m. the patient was completely unconscious, was cyanosed, had rapid heart action, and shallow respiration. Coffee, strychnine, and nitroglycerine were given, and later whiskey and digitaline, but without the least effect, and death occurred at 9.15 a.m. Dr. Sexton thinks that the case proves the existence of a special idiosyncrasy to the action of scopolamine, and believes that this may have been heightened in the present case by a dose of trional given over night. He believes that scopolamine is undoubtedly dangerous to elderly, and to decrepit or cachectic individuals. M.

A CASE OF POLYMYOSITIS.

PREBAJINSKY and Mayoulcis (*Revue de Medicin*, 1905, Nos. 10 and 11), report a fatal case of subacute polymyositis with autopsy record. In addition to the myositis, there was pulmonary tuberculosis. Besides the changes in the muscles, the motor cells of the spinal cord and of the medulla showed changes, while the peripheral nerves were normal. The muscle fibres varied much in thickness and were here and there degenerated and broken up; some of these appearing homogeneous, and some of them fragmented; the blood-vessels in the interstitial tissue were increased in number and showed slight thickening. Scarcely any of the muscles of the extremities escaped. The co-existence of tuberculosis and polymyositis is by no means a rare one; apparently the tuberculous poison exerts a harmful effect on muscles, in the same way as it does upon nerves. The cases always run a fatal and usually a subacute course. Myocarditis and heart weakness are common, and when degeneration of the respiratory muscles is added, the unfavourable termination is hastened. M.

NOTE.—A summary will appear each week in the following sequence:—

- 1.—"Recent Medical Literature."
- 2.—"Recent Surgical Literature."
- 3.—"Recent Gynecological and Obstetrical Literature."
- 4.—"The Recent Literature of Anatomy, Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

COMMON HEPATIC STIMULANTS.

A correspondent calls attention to the comparative neglect into which that most excellent of cholagogues, podophyllin, has fallen in recent times. There can be no doubt as to the great value of that drug, but we fancy it enters into the composition of a great many hospital aperient pills, as well as those popular in many a private practice. Of other hepatics, eunoinin is worthy of much greater attention than it usually receives from practitioners. It requires to be followed by a saline aperient. Iridin, again, is of great value in "liver" cases.

CANVARDINE.—The case should be of considerable interest. The personal history is more than suggestive of tubercle, and we suggest the diagnostic injection of O.T. tuberculin by way of confirmation. We shall be very pleased to insert the case as a clinical record.

M. O. H.—The question of "return" cases of scarlet fever and other infectious diseases has been fully dealt with in a series of original papers published in THE MEDICAL PRESS AND CIRCULAR in 1904. Whatever the general tendency of notification and isolation may be in the long run with regard to the two maladies mentioned, it certainly has not so far reduced the incidence of the disease. Mortality, however, has fallen considerably in both instances.

COUNTRY PRACTITIONER (Dorset).—The only observation that occurs to us dealing with your query is that blistering formerly applied to a bald head in the treatment of insanity resulted in some cases in a growth of lanugo hair. Our scientific knowledge of the whole subject, however, is yet in its early and empirical stages.

THE MOST POPULOUS CITIES OF THE WORLD.

The official returns of the great cities from which the Registrar General receives statistics, excluding of course such as the Chinese whence no enumeration comes to hand, are as follows:—London, 4,684,794; New York, 3,948,191; Paris, 2,680,559; Berin, 2,035,815; Chicago, 1,932,315; Vienna, 1,897,630; Philadelphia, 1,438,318; St. Petersburg, 1,248,122; Moscow, 1,092,360; Rio de Janeiro, 850,000; Calcutta, 847,798; Buda-Pesth, 836,267; Glasgow, 809,936; Bombay, 778,008; Hamburg, 772,852; Liverpool, 730,143; Manchester, 631,185; Boston, 617,950; Birmingham, 542,858; Amsterdam, 554,240; Madras, 509,346; Brussels, 566,936; Rome, 514,930; Munich, 528,000; Copenhagen, 428,000.

SPMS.—The subject has been under discussion for some time, and we hope to give an answer very shortly.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 3rd.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. F. E. Taylor, Dr. Horrocks, Dr. V. Dickinson, Dr. Griffith, Mr. H. J. Paterson, Dr. Galabin, and Mr. Dudgeon. Short Communication:—Dr. Milligan: Pylonephritis of Pregnancy. Paper: Dr. Griffith and Dr. Williamson: Fibro-myoma of Uterus undergoing Sarcomatous Change.

THURSDAY, JANUARY 4th.

RONTGEN SOCIETY (20 Hanover Square, W.).—8 p.m. Presidential Address:—Prof. F. Soddy: The Present Position of Radio-activity.
NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital N.).—4 p.m. Clinical Cases.

FRIDAY, JANUARY 5th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith, W.).—8 p.m. Clinical Meeting.

THURSDAY, JANUARY 11th.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Annual General Meeting. The President's Valedictory Address (Dr. William Alexander).

Vacancies.

Bristol Royal Infirmary.—Pathologist, Bacteriologist, and Director of Clinical Laboratories. Salary £250 per annum. Applications to W. E. Budgett, Secretary and House Governor.
University of Birmingham.—Demonstratorship in Anatomy. Salary £175 per annum. Applications to George H. Morley, Secretary.

Londo Fever Hospital, Liverpool Road, N.—Resident Medical Officer. Salary £250, with board and residence. Applications to the Secretary, W. Christie.
National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, London, W.C.—Resident Medical Officer. Salary £100 a year, with board and residence. Applications to Godfrey H. Hamilton, Secretary.
University of London.—Chair of Protozoology. Professor of Protozoology. Salary £750 per annum. Applications to the University of London, South Kensington, S.W.

Appointments.

CLARK, SYDNEY, M.R.C.S., L.R.C.P. Lond., Honorary Medical Officer in charge of medical cases at the South Leeds Branch of the Leeds Public Dispensary.
GRANT, DUNDAS, M.D. Edin., F.R.C.S. Eng., Consulting Aural Surgeon to the Royal Scottish Corporation.
JAFFREY, F., F.R.C.S. Eng., Surgeon to St. George's Hospital.
JONES, LAWRENCE, L.R.C.S. Eng., Assistant Surgeon to St. George's Hospital.
MACKENZIE, A., M.B., B.C. Cantab., Honorary Medical Officer in charge of surgical cases at the South Leeds Branch of the Leeds Public Dispensary.
NICOL, J., M.B., M.S. Aberd., Certifying Surgeon under the Factory and Workshop Act for the Alford District of the county of Aberdeen.
RALPHS, F. GERALD, M.B., Ch.B. Vict., Senior Resident Medical Officer at St. Mary's Hospital, Manchester.
SHARP, ALEXANDER D., Honorary Surgeon for Diseases of the Nose and Throat at the Leeds Public Dispensary.
SHARP, J. GORDON, M.D., C.M. Edin., Honorary Medical Officer in charge of medical cases at the South Leeds Branch of the Leeds Public Dispensary.
TRASDALE, J. O., M.B., B.S. Vict., Certifying Surgeon under the Factory and Workshop Act for the Retford District of the County of Nottingham.

Births.

FORBES.—On Dec. 27th, at 1 Oakwood Court, Kensington, London, the wife of J. Graham Forbes, M.D., M.R.C.P., of a daughter.
MACFADDEN.—On Dec. 28th, at 30 Frogmal, Hampstead, the wife of Cecil J. R. MacFadden, M.D., of a daughter.
ORMEROD.—On Dec. 23rd, at Southam, Warwickshire, the wife of Ernest William Ormerod, M.R.C.S. and L.R.C.P. Eng., of a daughter.
SOPER.—On Dec. 29th, at 307 Clapham Road, London, the wife of Bertram Soper, L.R.C.P. (née Frances Ash), of a son.
WELLS.—On Dec. 26th, at 107 Fordwych Road, West Hampstead, the wife of F. Barber Wells, M.B. Lond., of a son.

Marriages.

BEVAN—LAND.—On Dec. 27, at the Cathedral, Cape Town, Llewellyn Edgar Williams, of Salisbury, S. Rhodesia, elder son of Richard Bevan, L.R.C.P. Lond. and D.P.H., of 31, Girdlers Road, West Kensington, to Violet Isolan Marj, youngest daughter of the late William John Land, M.R.C.S., of Tonbridge, Kent.
KEALEY—BAYLEY.—On Dec. 7th, at Holy Trinity Church, Bolsum, India, Edward Herbert, I.C.S., of the Indian Political Department, fourth son of I. R. Kealey, Esq., M.D., of Alverstoke, Hants to Florence Tempe, eldest daughter of C. S. Bayley, Esq., I.C.S., C.S.I., of the Residency, Hyderabad, and Kirklanu, Reading.

Deaths.

ADAMS.—On Dec. 28th, Thomas Rutherford Adams, M.D., J.P., of 171, St. James' Road, East Croydon, aged 87, son of the late Thomas Rutherford Adams, of Kilmoganny, co. Kilkenny.
DANIEL.—On Dec. 30th, at the Silver Birch, Epsom, William Clement Daniel, M.D., M.R.C.S., L.S.A., aged 65 years.
ELTON.—On Dec. 28th, at Hunter Street, Brunswick Square, London, Henry Robert Elton, in his 45th year, third surviving son of Sur-Maj. H. N. Elton, of 12 Fordwych Road, Brondesbury.
GRAY.—On Dec. 28th, at 92 Aerley Park, London, Thomas Gray, M.R.C.S. Eng., and L.S.A., formerly of 12 Mountague Place, Poplar, E. in his 90th year.
PLATT.—On Dec. 29th, at 1 Clegg Street, Oldham, Thomas Platt, J.P., Surgeon, M.R.C.S. Eng., aged 72 years.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5jd.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, 25 Os. 0d.; Half Page, 22 10s. 0d.; Quarter Page, 21 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.
Small announcements of Practices, Assistantcies, Vacancies, Books &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

No. 2.

NOTES AND COMMENTS.

Amalgamation of the London Medical Societies

So far as can be seen at present there is every prospect that a more or less complete amalgamation of the London medical societies will take place, and that London will once again follow where Ireland has led the way. So long ago as 1882, the medical societies of Dublin agreed to amalgamate, and since then the Royal Academy of Medicine in Ireland has successfully taken their place. Of course, it is natural that some of the older societies should feel a difficulty in cutting themselves adrift from former associations and histories, and we understand that the Medical Society of London find themselves constantly faced with this difficulty. Still, all amalgamations necessitate a certain amount of self-sacrifice, and, if the Medical Society find themselves able to acquiesce in the scheme, it will have the satisfaction of knowing that its action is for the common good. For instance, can anyone doubt that the fraternisation of the Fellows of the Obstetrical and Gynæcological Societies would result in raising London prestige in these two subjects to the position which it ought to occupy. If we do not fall divided, we certainly should stand much stronger if united.

Wanted, a Name.

OUR contemporary the *Practitioner*, draws attention to an important *quæstio vexata*, namely, that of the future title, of the conjoined societies. The proposed title "The Royal Society of Medicine," is, as is pointed out, most objectionable, both because it is a colourable imitation of that distinguished body, The Royal Society, and also because it gives the Fellows of the latter body an excuse for resisting the claims of medical men to their Fellowship on the ground that they have a "Royal Society" of their own. Why should not the Dublin lead be followed a step further, and the title "The Royal Academy of Medicine of London" be adopted? Possibly some enthusiast may go still further, and suggest that there should be a Royal Academy of Medicine of the United Kingdom.

The Fellowship of the Royal College of Physicians of Ireland

APPROPRIATELY with the commencement of the New Year, the Royal College of Physicians of Ireland is able to make an important announcement, which we fancy will be well received by the profession in Ireland.

Up to the present, intending candidates for the Fellowship of the College were obliged to pass first an examination for the Licence of the College, and then one for its Membership. As the first of these examinations included practically all the subjects necessary for qualification save surgery, this meant

that men occupying high positions as consultants of as specialists in various departments had, if they desired to become Fellows to return to their student days. To obviate this the College applied during the past year for a new Charter, and this, which was duly granted, confers upon them the power of admitting to the membership examination graduates of all British Universities, Licentiates of the Royal Colleges or Physicians of London and Edinburgh, and, under certain conditions, medical practitioners holding foreign qualifications. Accordingly candidates for the Fellowship have in future to pass only one examination, which will embrace the principles, theory and practice of medicine and clinical medicine. This alteration should, we think, be largely instrumental in inducing many of the provincial consultants of high standing in Ireland to offer themselves as candidates for the Fellowship of the College.

Damages for "Barber's Itch."

THERE is a more effectual way of securing cleanliness and reasonable precaution in barbers' shops than by making regulations, and that is by suing barbers who propagate filth-diseases. It is a pity that sufferers are apathetic with regard to their own interests, for half-a-dozen successful actions would bring the hair-dressing fraternity to a realisation of their responsibilities considerably more quickly than all the sanitary precepts that medical officers of health try to instil into them. In the Marylebone County Court on New Year's Day a male nurse was awarded £15 damages against a barber for having inoculated him with "barbers' itch" in the course of a shave. The shop appears to have been a cleanly one, but the plaintiff when cross-examined on this point made the apt remark that "it was impossible to see a microbe on a razor." Expert evidence was called on both sides, but there was no doubt that the patient had had a skin affection of some severity, and the jury took the view that it was caused by the shave. We hope the case will be widely noticed and commented upon, for the point being established that such an occurrence is due to want of proper care, it may be hoped that barbers will be stimulated to adopt those precautions which have so long been in vogue in France and elsewhere.

SIR JOHN BATTY TUKE, the present Unionist member for the Parliamentary seat of the Universities of Edinburgh and St. Andrews, last week issued his election address. Sir John is one of the few medical men in the House who has never permitted his professional obligations to be swamped by the pressure of party politics. In season and out of season he has advocated reforms of first importance to medical men. In the present election he has a strong adversary in the person of Mr. St. Loe Strachey editor of the *Spectator*.

The absolute necessity of sending medical men into Parliament, however, has been so widely recognised by our profession in recent years that the bulk of the Edinburgh and St. Andrews doctors of medicine will probably cast their votes in favour of Sir John Tuke. In these Universities the medical vote far exceeds that of all the other faculties put together.

LEADING ARTICLE.

MEDICAL REQUIREMENTS AND THE GOVERNMENT.

WITH a New Year and a new Government the medical mind turns naturally to thoughts of legislation as applied to medicine and hygiene. Will the Liberal Party if returned to power at the General Election show themselves accessible to scientific ideas, or will they be content to plod on in the ruts left by the wheels of custom and tradition? We have read latterly in the press wholesale appeals to fashion our institutions and equipment on modern and scientific lines, the word "efficiency" has been on everybody's lips. Naturally at this time from a thousand platforms comes its echo; is it to remain nothing but an echo? That question seriously concerns all medical men who look beyond the jarring needs of the moment to the larger needs of the immediate and more distant future. At no period in modern history has advance in industrial and commercial matters been as rapid as during the last fifty years, and coincidentally with it consequent upon that advance a shoal of problems affecting the lives and health of people have sprung into being; something doubtless has been done towards meeting and tackling these problems, but when these are considered in all their aspects one must admit the fringe only has been touched. Now, truism as it may appear, it is worth re-affirming that if successful solutions are to be attained they must be attained by scientific methods. These questions have become too large to be resolved by any rule of thumb or happy inspiration. The first requisite in proceeding towards a solution is that the facts and elements should be martialled; the second, that they should be seriously studied. For medical men the problems of disease primarily arrest attention, and to their trained vision it seems that no progress which involves added disease is sound progress, and no commercial prosperity that entails suffering and early death is worth the candle. It seems to them a duty for the State to aid in the work that is now unostentatiously being performed in studies and laboratories to ascertain the causes, the means of prevention, and the mode of cure of diseases. To assert that every scientific investigation of the moment is starved for want of funds, is but to use the language of sober fact; it is, moreover, an understatement, for hundreds of such investigations which should be pursued are not undertaken for the same reason. What does the Government do for research? A few beggarly grants are made

to the Royal Society; occasional fees are paid to scientific men to undertake special investigations for individual departments, such as the Local Government Board and Home Office or for Royal Commissions; and payments are made towards the upkeep of such institutions as the Royal College of Science, which indirectly encourage private research by the professors. In an age when science is the *motif* of the whole social fabric, what can be thought of these stingy subsidies? We know from the public utterances of the late Prime Minister and of his principal lieutenant, Mr. Chamberlain, that they both realise in no small degree what research means to the happiness of the people and the prosperity of the Empire, and yet no member of the late Government had the courage to propose the grant of a substantial subsidy towards its prosecution. Will the Liberal Government, or such a Government as shall emerge from the dust and shoutings of the polls, be any wiser and any stronger? We confess we are not sanguine, but if they can be induced to propose such grants we confess we do not see how, in the light of their spoken words, the leader of the Opposition and his followers could demur. Nor, indeed, is it likely that they would. The need for the endowment of scientific research is tacitly admitted by all thoughtful men; it only remains for an advocate to bring it forward in a practical form and for a broad-minded Chancellor of the Exchequer to find the money. When the sums now available for the purpose are considered, it is tantalising to reflect what might be accomplished for the cost of a battleship or of a punitive campaign against an obstreperous savage chief—either of which would be voted without discussion in almost any House. If it be urged that such payments would not be directly utilitarian, we should reply not only that in many cases they would, but that they would at least be comparable to expenditure on education, the necessity for which no one disputes. Residents in the tropics and commercial magnates at home acknowledge with gratitude the beneficial effects on health and trade that Sir Patrick Manson and his school have conferred by their private investigations, and the incidence of tuberculosis and typhoid—to say nothing of small-pox—has been enormously reduced through proper application of the factors at work in their productions and prevention. We venture to believe that a grant of even £100,000 a year to disease-investigation and study would not only soon be recouped, but that it would bear interest a thousandfold—what proportion, too, does £100,000 bear to a national expenditure of over £140,000,000? Surely such a sum could be easily provided if it were not for inertia, want of imagination, and—should it be added?—the anti-vivisectionists.

The Chemistry of Violet Leaves.

VIOLET leaves have been so widely advocated in the public press as a remedy for cancer that it

is desirable to have some exact scientific information upon the subject. An excellent essay in that direction has been made by Mr. G. H. Whippell Gadd in a paper recently read before the Therapeutical Society. Negatively he found no volatile constituent, no alkaloid, and no salicylic acid. On the other hand, he demonstrated the presence of a glucoside, nine-tenths of which was found in a fresh infusion of the leaves. This glucoside has not been isolated, but if there be any therapeutic virtue in the leaves, it must pretty obviously lie in this constituent. The next step would be to test the glucoside therapeutically. While not denying the remote possibility of violets possessing some quality antagonistic to malignant neoplastic growths, we think it extremely unlikely; at any rate we should want convincing scientific proof of its benefits in a large number of cases before we recommended it on clinical grounds. It is cruel and inhuman to delude patients suffering from a terrible malady by crude and hasty theories formed by persons untrained in the A B C of observation and of sound reasoning.

Visiting Physicians or Resident Medical Superintendent?

We drew attention a few weeks ago to the forthcoming vacancy on the visiting staff of the Cork Street Fever Hospital, in the hope that thereby the widest publicity might be gained, and that the Governors of the Hospital might have a large field of suitable candidates from whom to select. We understood that the Governors intended to hold the election in the present month, but we have since learned that they have in consideration a step of serious nature. It is proposed, in short, to leave this and future vacancies unfilled, thereby depriving the Hospital of the attendance of a staff of visiting physicians, and leaving the care of the patients to the resident staff, aided in cases of difficulty by consultants. While much may be said on behalf of the Hospital in favour of such a scheme, something is to be said on the other side from the point of view of the profession and the public. In the first place, the present plan has always worked admirably, and the Governors have never had any difficulty in securing the services of the ablest of the younger physicians of Dublin. But the most important result of the present system is that by the necessary retirement of a physician after seven years' full service on the staff, the profession in Dublin has always had in its ranks a number of men highly educated in the diagnosis and treatment of acute zymotic diseases. This constitutes, we believe, an asset of great value to the community at large, and one that it will not be easy to replace. In the event of a serious epidemic, Dublin may have to face a disease with which its medical practitioners are almost unacquainted. We have no doubt the Governors of the Fever Hospital will exercise a wise discretion in their consideration of the question now before them, and we trust that the point

of view we have put forward will not be lightly overlooked.

Fogs and Open Air Treatment.

It is a common remark of persons who as a rule sleep with open windows, "Of course we are obliged to shut the bedroom windows when a fog comes on." Why this should be so is not clear. A stuffy bedroom is just as harmful in foggy as in fine weather. Closing the windows may shut out the mistiness of the fog, but it does not exclude its baleful products. When cabmen and other persons are said to be suffering from the effects of fog, it is just as likely that fatigue, cold, wet and other depressing conditions are at fault. In some asthmatics fog brings on an attack, but, on the other hand, quite as many sufferers are thereby cured of their asthma. Certainly London fogs do not prevent consumptives from being cured by sleeping and living in the open air. In some London hospitals patients have recovered from lung tuberculosis while passing their nights on open-air balconies freely exposed to fog and other vicissitudes of weather. That fact speaks volumes, and we must fain conclude that from a medical point of view the London fog is not half so black as it is commonly painted by the journalistic brush. Some newspaper men have adopted the curious plan of cross-examining house surgeons at hospitals as to the good or evil influence of fogs. Residents of that kind are mostly young men, full of a vast store of examiner's knowledge but lacking the ripe experience needed to tackle so intricate a problem as the effect of fogs in health and disease. Newspapers, please copy.

Health Lectures in the Army.

SEED in incalculable shoals has been sown on the stony ground which the military brain presents to the medical reformer, and at times he may well despair of seeing any fruit for his pains. But some patches of good soil have been discovered among the stones, and now in a tentative meticulous way the shoots are beginning to sprout. One gratifying piece of evidence of this fact is furnished by the orders of the General Officer Commanding-in-Chief in Scotland, for it is announced that the General has arranged for a series of lectures on barrack and camp sanitation, and on health during a campaign, to be given to the rank and file during the winter months. These lectures are to be delivered at each of the chief military centres, and it is hoped that they will be well attended. They are to embrace the questions of the purity of water, filtration and sterilisation, camp diseases, refuse disposal, disinfection, sunstroke, blistering of the feet, scurvy, alcohol drinking, venereal diseases, ventilation, consumption, and tropical diseases. We wonder what Lord Wolseley would think of occupying the spare time of soldiers with such trivialities. But when the amount of misery and loss caused by preventable diseases in the Army is taken into account surely any sensible man—medical or lay—will admit that the new departure is worthy of all praise. We congratulate Sir Charles Tucker on his bold departure from War Office tradition.

Science and the New Cabinet.

CLEARLY the endowment of scientific research and the true appreciation of the value of science to the community should be part of the programme of every progressive Government. Yet politics are for the most part permitted to swamp all claims of modern science to State recognition. The result is that scientific men are often compelled to choose the road of high thinking and penurious living, while science herself has to depend on the precarious gifts of philanthropy. Professor Clouston, the distinguished vice-President of the Edinburgh College of Physicians, has uttered a timely warning note in the present season of Parliamentary reconstitution. "Many of us think," he writes, "that questions relating to science and to health are of such enormous importance to the future of our people that they should take a first place in the consideration of His Majesty's Government and the coming Parliament. They touch every house in the land. They mean much for the efficiency of our industries, our shipping, and our sources of wealth. Many people have looked with much anxiety to see if anything is said about science and its prospects in the discussions as to the *personnel* of our new Cabinet. As yet, I have never seen a single speculation in the reams of newspaper discussions as to whether any candidate for a seat in the Cabinet has any scientific interests or knowledge, or any special enthusiasm for the health and bodily and mental welfare of the people. Every name that I have seen mentioned would be a mere amateur in matters so vital to the nation."

Registration of Plumbers.

IF the old lady who found such spiritual comfort in the word Mesopotamia were to be resuscitated from the grave in which she must have lain since time immemorial, and were she to be asked what was now the most blessed word in the language, we have no doubt she would reply—"Registration." There are few ills of the body politic for which registration has not been proposed, and equally few we fear which it has charmed out of existence. But we live in a day of small things, and must be content with such crumbs as fall from the Parliamentary table. Wherefore we heartily wish success to the promoters of those Bills which are annually introduced for the registration of plumbers. Most householders and all medical men regard the plumber as a blessing in disguise, much as we were accustomed to regard disease till we were enlightened as to its true nature by Sir Frederick Treves. The plumber is as necessary as he is often not harmless, but thanks to the efforts of the various hygienic associations and the energy of the Plumbers' Company a good deal is being done by lectures and examination to teach him his trade and to impress him with his responsibilities. Employed as he is in the bowels of the house and on work which the householder understands as little as he does Hebrew, the plumber

has admirable opportunities for displaying undiscovered both incompetence and deceit. With a State-recognised register, the useless and evil-disposed could be brought under discipline, and none could gain enrolment without examination. The machinery for administering a Registration Act has been already provided in the District Councils for the National Registration of Plumbers which exist in many parts of the country, and examinations and a voluntary register are already in being under their auspices. Moreover, the proud initials, R.P. are beginning to blossom out over plumbers' shop-fronts. This machinery deserves popular if not legal recognition.

Medical Men in Parliament.

IN the British Parliament there has never been any party that could strictly be called medical, that is to say, in the sense that there is a legal, or an army, or a brewing, or a shipowning, or a railway element. The absence of an organised professional section, however, has not excluded many distinguished medical men, but they sit in the House to represent their constituencies in the first and often also in the last instance. To this state of affairs the present election offers no exception. Among the candidates are about a score holding medical qualifications. With but three or four exceptions, these gentlemen cannot be considered in any way leaders or even representative men of their profession. In fact, the majority enter the lists purely as politicians and should they gain entrance to the House of Commons will sit as mere party supporters and exercise little or no influence in the building up of sound scientific views and the securing of sane measures relating to national hygiene. It is also to be noted that the present Cabinet, whilst representing law, literature, and commerce, has no member of any distinction as a scientific man, and yet the all-important matter of national health is left uncared for, or at all events inadequately provided for, by any responsible minister. With serious physical disabilities hampering a large section of the community and widespread deterioration prevailing amongst our working classes, as well as vast mental and bodily inefficiency among those on whom we depend for our country's protection, surely the time is ripe for the appointment in any progressive government of a Minister of Health. Both science in general and medical science in particular demand full recognition by the lawmakers of the twentieth century.

Quack Legislation.

WHEN the immense amount of harm done and suffering caused by illegitimate practice is considered, the desire of the reformer naturally is to seek legislation to make such practice impossible. The same reflection occurs, too, with regard to quack medicine. Unfortunately, it is quite impossible to expect, with a reasonable degree of confidence, that any House of Commons within the

next few years is likely to pass any provisions of the kind, and it is a question for practical statesmanship how to devise any measure that will be acceptable in itself and that will lead to more extended control in the future. A hint on this subject may, we think, be gathered from the action about to be taken in New Jersey and several other Eastern States of the American Union. A courageous and vigorous warfare has been carried on by one of the lay newspapers in America against quackery and patent medicines, and the public conscience has been considerably stirred by the consequent exposures, so that practical means are now being sought wherewith to fight the continuance of this form of fraud and greed. A neat plan is proposed. By bills which are being introduced into the legislatures of the various States concerned in the movement, it is enacted that the vendors of all proprietary medicines must disclose on a label affixed to each bottle the ingredients that the bottle contains and the proportions in which these ingredients are mixed. Moreover, the actual monetary value of the ingredients is to be stated and the price of the preparation fixed accordingly. Nothing could be simpler and nothing could be less open to objection if the business were a genuine one. On the other hand, the Bills, if passed, are likely to knock the bottom out of the whole patent medicine trade, and they are to be strenuously opposed by the newspaper and quack drug interests. We need hardly say that we wish them a safe and easy passage, if only as an example to our own country.

Wounds of the Heart.

TILL within the last few years the only wounds of the heart that were known to be recovered from were those purposely inflicted by wanton novelists on their susceptible heroes, and even these underwent a course of cicatrisation that lasted through three volumes before the final apotheosis of love and reconciliation was reached. But it is now known for certain that some wounds of the heart are amenable to surgical treatment, and recoveries have been met with in Great Britain and on the Continent. One case in this country, indeed, was so successful that the patient when restored to his old surroundings was able to renew his old relations with the police, and was recently before the magistrate for an assault committed while he was under the influence of his favourite drug. Still, such recoveries are rare, and we notice that two interesting cases were lately shown to the Surgical Society in Paris. In one the patient, a man, had been stabbed in the breast by a knife, and when seen half an hour later showed all the signs of internal hæmorrhage combined with largely increased præcordial dulness. A flap consisting of the third, fourth, and fifth rib-cartilages and their integuments was laid back, and the pericardium, which was bulging, opened. Three hundred grammes of blood flowed out, and a wound in the left ventricle was discovered and stitched up. In spite of a subsequent operation for hæmothorax,

the patient left the hospital cured in three weeks. The second case was that of a woman who had been wounded by a revolver-bullet, which produced hæmorrhage into the left pleura. In the course of an operation for the relief of this condition, a wound was found in the left ventricle, but as it did not bleed no suturing was carried out. She, too, recovered completely.

PERSONAL.

H.R.H. THE PRINCE OF WALES on laying the foundation stone of the Victoria Memorial Hall, in Calcutta on Thursday last, presented the magnificent sum of £6,000 to the Calcutta Medical College.

ON Christmas Day Dr. J. C. Martin was presented by his numerous friends in Portrush with a silver casket suitably inscribed and containing 250 sovereigns. The occasion was Dr. Martin's return after a prolonged absence due to illness.

At the last ordinary meeting of the Royal College of Physicians of Edinburgh, Dr. John Playfair was re-elected President of the College.

DR. JAMES MORRIS, who has recently tendered his resignation of the medical officership of health in the burgh of Dunfermline, has held that post for no less than forty-five years.

ON the 3rd instant a handsome testimonial was presented to Dr. Spooner, the senior medical inspector under the Emigration Department in Liverpool, on the occasion of his retirement after thirty-two years' service.

THE news was published in the daily papers on Friday last that Dr. J. F. Stewart, son of Dr. Stewart of Belfast, had been murdered and his body partially eaten by Nigerian cannibals. A notice of this shocking occurrence appeared in our columns six weeks ago.

THE opening lecture of the Spring session of the North-East London Post-graduate College will be delivered by Mr. John Langton, F.R.C.S., consulting surgeon to St. Bartholomew's Hospital, on January 12th, at the Tottenham Hospital, N. The afternoon clinical lectures throughout the session are free to all qualified medical practitioners.

MR. HENRY LABOUCHERE, now elevated to the honour of a Privy Councillorship, has proved himself a true friend to the medical profession by his fearless exposures, in the pages of *Truth*, of quackery, and deserves our best congratulations.

PROFESSOR W. R. SMITH, M.D., of Aberdeen, and D.Sc. of Edinburgh, now Mayor of Holborn, and a member of the Metropolitan Asylums Board, is fighting Sir Henry Craik, K.C.B., M.A.Oxon., LL.D. Glasgow and St. Andrews, for representation of the Universities of Glasgow and Aberdeen.

MAJÖR T. H. F. CLARKSON, Senior Medical Officer in Jersey, has been appointed to succeed Lieut-Col. J. Meek at the Tower of London on February 1st.

THE German Empress has placed herself at the head of a committee with the object of erecting a model institution for the care of infants, to be built in a West-end suburb of Berlin, at an estimated cost of 4,000,000 marks. Gifts of money to the Imperial pair on the occasion of their approaching silver wedding will be devoted to the erection and endowment of this institution, which it is stated will be the most complete of its kind in the world.

A CLINICAL LECTURE

ON THE

DIAGNOSTIC VALUE OF ALTERATIONS

OF THE

PULMONARY SECOND SOUND IN CARDIAC DISEASE.

BY
Sir CHRISTOPHER NIXON,
 Senior Physician to the Mater Misericordiarum Hospital.

GENTLEMEN,—The case which is at present under observation in St. Gabriel's Ward affords me an opportunity of directing your attention to the diagnostic value of certain signs observable in connection with the pulmonic sound of the heart. The case referred to is one of pulmonary regurgitation due to relative inadequacy of the pulmonic signoid valves, an extremely rare form of cardiac disease. The patient, a young woman, *æt.* 27, presents many of the typical signs of mitral stenosis, but on examining over the pulmonary area instead of hearing the sound of Skoda, a loud and somewhat lengthened diastolic murmur is to be heard. This murmur takes the place of the second sound, and is transmissible downwards in the direction of the right ventricle. The sounds heard over the aortic area are normal in character, the two cardiac sounds are distinctly pronounced in the carotids, there is no visible pulsation in the arteries of the neck or upper extremities, and the radial pulse presents none of the features that distinguish it in aortic inadequacy. I have no doubt of the condition being one of pulmonary regurgitation, it being the second instance of this lesion which has come under my notice within the past six months. Very frequently, as you are aware, both in mitral stenosis and regurgitation, the increased tension in the pulmonary artery results in an accentuation of the pulmonic sound, a condition pointed out by Skoda over fifty years ago. It is well, however, to lay stress upon the factors producing this accentuation. Obstruction to the circulation through the pulmonary capillaries, whether due to affections of the lungs, such as emphysema or cirrhosis, or to lesions of the left auriculo-ventricular valves, does not necessarily lead to the production of Skoda's sound. It is only when the increased tension in the pulmonary artery is reinforced by the contraction of a hypertrophied right ventricle that the sound becomes accented. A large number of cases of both mitral regurgitation and obstruction do not present this sign, in those, for instance, where compensation is defective. This may be due to a variety of conditions, the age of the patient, his condition of general nutrition, the extent of the lesion in the valve, and the absence of those favouring circumstances which determine generally compensation. In the latest stages of mitral disease two conditions may be set up which lead to diminished rather than accented quality of sound over the pulmonary artery, the occurrence of relative incompetency of the tricuspid valve, and a condition of right ventricular fatigue, such as we observe in cases of aortic patency in connection with the left ventricle. This condition of fatigue or weakness of the right ventricle is one not sufficiently impressed upon our attention, although I believe it exercises a potent influence on the progress of heart lesions generally. In this and in relative tricuspid regurgitation, the result is alike, diminished pulmonary tension, and a weakened pulmonic sound. In the case under observation, the tension in the pulmonary has been so considerable that there is reasonable ground for the assumption that the arterial ostium has been so stretched as to render the valves relatively inadequate, hence the murmur of regurgitation replaces the usually accented second sound. This condition of pulmonary regurgitation was made the object of special study by Barié, who collected some 58 cases of the lesion, most of which occurred between the ages of 18 and 34, and were traceable to endocarditis, the result of rheumatism, various infective fevers, and an atheromatous

condition of the pulmonary artery caused by chronic alcoholism. There can be no doubt, too, that a large proportion of cases is due to congenital malformation of the artery itself, and of its valves. But apart from conditions of altered structure in connection with the pulmonary valves producing leakage, there are good grounds for the acceptance of the view that relative or functional incompetency of these cusps exists. Hunter held that a natural provision exists by which the valves of the right side of the heart, pulmonary as well as tricuspid, did not exercise as perfect a function as those of the left, that what was necessary for the systemic circulation would be harmful, if incapable of modification, as regards the pulmonic circulation. Stokes early recognised this condition, and so subsequently did Gouraud, who contributed a valuable monograph on the influence of pulmonary affections on the right side of the heart, and the condition of relative incompetency of the pulmonary artery which they produce. Not many years ago some interesting experiments were performed by Dr. Gibson, of Edinburgh, in connection with pulmonary inadequacy. He showed that under the pressure of columns of fluid of various heights in the pulmonary artery of the ox, sheep, and of the human heart, a condition of relative incompetency could be readily produced from distension of the artery. It was, however, at a much later period that Dr. Gibson satisfied himself of the absolute evidence of this condition as a result of disease. More recently Jawinsky, Barr, and Graham Steele have drawn attention to the soft blowing diastolic murmur heard over the pulmonary artery in mitral stenosis, a murmur appropriately named by Dr. Graham Steele "the murmur of high pressure in the pulmonary artery." So quite apart from the legitimate acceptance of pulmonary regurgitation from the signs present in the case under observation, we have high authority for recognising the existence and mechanism of this phenomenon. In dismissing the question of the conditions under which the sound of Skoda is produced, I should like to emphasise the point that within very broad limits the sounds of the heart vary markedly in intensity in different individuals. Many circumstances quite consistent with health render the sounds more or less audible, a condition largely influenced by temperament. Thus nervous persons under conditions of excitement have the sounds sharply intensified; this is what ordinarily takes place during palpitation. On the other hand, phlegmatic persons, often of obese conformation, have their heart sounds obscure and ill-pronounced. Again in emaciated persons, where the chest walls are thin, and where the osseous structures and the skin have not their conducting properties interfered with by the existence of a non-conducting material like fat, both heart sounds at apex and base are sharply marked. In emphysema all the sounds of the heart may be obscured by the voluminous cushion of lung which intervenes between the heart and the chest wall, a point which accounts for the absence of the sounds of Skoda in this condition. All these varieties as to the character of the sounds of the heart in health and disease can only be learned by the constant practice of auscultation, and here let me quote for you the words of a great English classic, not read nowadays with the attention which its originality, its truthfulness to nature, as well as its terse and accurate form of expression deserve. I refer to Latham's work on "Diseases of the Heart." In the lecture dealing with the sounds of the heart he says:

"The sounds which naturally accompany the movements of the healthy heart can only be learned by the practice of listening to them. It is useless to describe them. They are simple perceptions of sense, which no words can make plainer than they are, when the ear has once become familiar with them. It is the same with all common sounds. By describing them you seek to make them known in a different form from that in which they are naturally known. Who ever thought of describing the sound of the wind or the rain except for poetical purposes? I must leave you, then, to be your own self-instructors in the healthy sounds of the heart, and recommend you to be constantly practising auscultation for the purpose on healthy subjects." Gentlemen, I could not in any way qualify this lesson.

Quite different in character, and in diagnostic significance from the diastolic murmur of pulmonary inadequacy is a murmur, diastolic in rhythm, which is to be heard occasionally over the pulmonary area, and on a plane lower down. It is usually grating in character, giving one the impression of an attrition murmur, but single in quality. It is generally met with in cases of acute rheumatism. The site of the murmur and its place in the cardiac cycle no doubt suggest pulmonary regurgitation due to pulmonic valvulitis. But you must bear in mind that this lesion is the rarest of all pathological conditions affecting the heart, whilst pericarditis is one of the most common. Furthermore the site of the diastolic murmur, which obscures the cardiac second sound, is in the situation corresponding to the earliest development of pericarditis, over the conus arteriosus and origin of the pulmonary artery. In those cases pain is frequently complained of over the region of the heart, and a symptom rarely absent even at commencement of pericarditis is present, viz., tenderness on pressure over the epigastrium. The progress of cases shows in the course of a few hours that the diastolic murmur is really an exocardial one, and it is in a short space of time replaced by the ordinary to-and-fro murmur of attrition. The murmur referred to may be regarded as an early sign of pericarditis.

The next point in connection with the pulmonary second sound is its re-duplication and division. If the breath be held after a deep inspiration under normal conditions, in most instances, a triple sound is heard at the base of the heart, the second sound being doubled. In some cases the two tones are not separated by a distinct interval, being more or less merged into each other so as to produce a roughish or murmurish sound. This constitutes what is known as division of the sounds, whilst in the case of the two elements being separated by a distinct interval, the condition is known as reduplication. It arises physiologically from the delay which inspiration causes to the filling of the left ventricle, thus producing a slight degree of alteration of pressure in the aortic and pulmonary systems. In a more marked degree reduplication is produced in mitral stenosis and in mitral regurgitation, but whilst in mitral stenosis, as after forcible inspiration, the aortic element of the two tones is produced before the pulmonic element, the opposite holds good in mitral regurgitation.

The explanation which I think satisfies those conditions is as follows:—The closure of the semilunar valves is effected the instant the blood ceases to flow from the ventricles, and is quite independent of the degree of pressure in either artery. The second sound is not caused by the closure of the valves, but by their sudden tension produced at the moment ventricular diastole begins. The closure is caused by the diastolic drop of pressure in the ventricle. Any factor which tends to prevent this lowering of pressure, as it delays the closure of the valves, must delay the occurrence of the second sound, whilst any factor favouring the lowering of pressure will hasten its production. Inspiration detains the blood in the pulmonary capillaries and in this way prevents the filling of the left ventricle, so that the difference in pressure in the interior of the ventricle and the aorta is greatly in-

creased, hence the aortic diastolic sound is hastened and produced before that of the pulmonary artery. The same thing holds good in mitral stenosis where the ventricle is slowly filled through the narrowed mitral orifice. But in mitral regurgitation the ventricle is rapidly filled under conditions of increased pressure, owing to the contraction of a dilated and hypertrophied auricle, so that here the tension of the aortic valve is delayed, hence the aortic sound follows that of the pulmonic. Careful examination of the sounds over the base of the heart will show which second sound is the later. Whilst the aortic sound is best heard over the aortic area, the pulmonic sound, markedly louder in character, is heard over the pulmonary area, preceding or following the weaker sound according to the conditions existent.

In discussing the mechanism of reduplicated second sound at the base of the heart a distinction must be carefully drawn between this phenomenon and the triple sound which is frequently heard over the apex beat in cases of mitral stenosis, sometimes described as apparent doubling of the second sound. This triple sound is present in one-third of all cases of mitral stenosis at certain stages of the lesion, though it may exceptionally be met with in other cardiac conditions. The mode of its production is in no way connected with asynchronism in the closure of the aortic and pulmonic valves. The triple rhythm represents three approximately equal tones heard best over the mitral area, the heart beating in $\frac{4}{4}$ instead of $\frac{3}{4}$ time. In some cases the first of the tones is replaced by a presystolic murmur, so this tone may be said to represent the auricular-systolic murmur of Gairdner. Where there is no murmur the anterior thickened segment of the mitral valve held in a condition of tension during the diastole of the ventricle, being taut from basic attachment to free margin, receives during the systole of the auricle a considerable accession of tension, with the result that a very distinct sound of presystolic tension is produced. This accounts for the first of the triple tones, a tone which can often be replaced by a presystolic murmur upon some active exertion made by the patient. The second and third tones are the altered first sound so characteristic of mitral stenosis, and the second sound of the heart.

Closely allied to the triple rhythm just described is the condition known as the gallop-rhythm, a phenomenon in which the interpolation of a third tone, simulating doubling of the first or second sound, produces sounds so closely resembling the hoof beats of a galloping horse, that it has been designated the canter-rhythm or Bruit de Galop. This peculiar triple sound is met with in many diseases altogether dissimilar in their nature such as many of the infectious fevers, diphtheria, croupous pneumonia, and in acute rheumatism with hyperpyrexia. We had quite recently in the fever wards a typical instance of it in a case of scarlatina in which signs of myocardial implication manifested themselves. There were present a small thready pulse—the *pulsus formicans*—cold extremities, congestion of the liver, and partial suppression of urine, and with these the bruit de galop. It has, too, been noted in pernicious anæmia, in leukæmia, exophthalmic goitre, and in various cachectic conditions in which there was pronounced cardiac asthenia. It is in connection with failing heart that it has been so frequently observed in the advanced stages of Bright's disease, especially that form known as interstitial nephritis, in which general arterio-sclerosis and hypertrophied left ventricle are usually associated. Galop rhythm in this condition is often a sign almost as pathognomonic of renal mischief as is the particular form of neuritis connected with albumenuria, whilst its presence is of great prognostic value as it indicates a form of cardiac insufficiency which is invariably progressive. There is considerable difficulty, where the conditions under which galop rhythm is developed are so diverse, in referring its causation to any disturbance in the valvular mechanism or to the state of the ventricle. The triple sound is heard over the entire heart, at the apex and at the base, sometimes louder over the neutral

area than the tricuspid, and *vice versa*, whilst the interpolated sound may be heard at three points of the cardiac cycle, immediately after the diastolic sound when it simulates a double second sound, in the middle of the long pause and at the presystole, when it simulates a double first sound. The weight of authority is definite as to the view that the interpolated sound is a diastolic phenomenon, and that it is produced quite independently of any alteration in the valvular mechanism. It is probable that the condition which is common to the various morbid states under which it is met with is an over stimulated cardiac activity, which leads to an abnormally quick diastolic relaxation with a consecutive sudden passive tension of the ventricular wall. This is due firstly to the *vis a tergo* of the entering blood, and secondly to the auricular contraction. Besides the pressure of the entering blood it should be borne in mind that, under normal conditions, the diastole of the left ventricle is not a mere passive act. It dilates under a negative pressure of 23.5 millimetres of Mercury (the *vacuile postsystolic* of Marey). If under conditions of disturbed innervation, associated with alterations of arterial tension, the abnormal degree of passive tension in the ventricular wall is produced at the commencement of diastole the third sound follows immediately the second sound, whilst in other instances the requisite of sudden passive tension is only reached during the auricular contraction, when the abnormal tone will immediately precede the first sound.

To summarise briefly, the points of diagnostic importance in connection with the pulmonic second sound in cardiac disease are as follow:—

1.—The rare condition of pulmonary incompetence from extreme dilatation of the pulmonary artery, a condition appropriately described under the name of "the murmur of high pressure in the pulmonary artery."

2.—The conditions necessary to produce the sound of Skoda in mitral disease, those under which it is not developed, and in which it undergoes resolution.

3.—The conditions relating to reduplication and division of the pulmonic sound.

4.—The condition of triple rhythm, simulating reduplication of the second sound, which is met with in mitral stenosis and that form of triple rhythm described under the name of the galop rhythm or bruit de galop.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's number will be by Professor Schüler, of Vienna, entitled "Essential Nephritic Hæmorrhage."

ORIGINAL PAPERS.

TUBERCULAR DISEASE OF THE SEMINAL TRACT. (a)

By LEVESON-GOWER GUNN, M.A., F.R.C.S.,
Assistant Surgeon to the Adelaide Hospital.

THERE are two classes of disease that must always be of interest to us, those that are very rare, and for this reason interesting, and those that are very common, for on our power of curing common ailments depends largely our measure of professional success. It is to a very common disease, namely tuberculosis, that I wish to draw your attention for a short while to-night. The genito-urinary tract is often attacked by tubercular disease; in some parts of this system the diagnosis may be beset with considerable difficulty. In that portion of the system, the testicle, the cord, the seminal vesicles, and the prostate, to which I wish to call your attention to-night, the diagnosis leaves as a rule no room for doubt.

When the question of treatment arises there seems to

be, on the other hand, considerable difficulty in selecting the best course to pursue; for this reason I hope that this paper, since it deals more particularly with the treatment of tuberculosis of the seminal tract, may prove of interest to you.

Tubercular disease may occur primarily in the kidney, the bladder, the prostate, the seminal vesicles or the testicle, or it may occur as a secondary deposit in any of these organs. The testicle is most commonly affected of all these, by testicle I mean both testis and epididymis, for the latter is more often attacked than the former. There is an interesting difference between the primary and secondary infection of the epididymis by tubercle. In the primary, the disease is deposited in the tubules, and from its commencement is in connection with the lumen of the vas; in the secondary, the infection more commonly occurs in the connective tissue outside the tubules, and it may be months before the bacilli gain entrance to the vas: this has an important bearing on the extension of the disease from a tubercular epididymis.

In what direction does this disease spread from the epididymis? Into the body of the testicle itself, where inflammatory changes or the actions of toxins, or perhaps both causes, early in the disease render the testicle functionless. The flow of seminal fluid along the vas is very slow, except during ejaculation, when the powerful muscular walls of the vas contract strongly, the tubercle bacilli are carried along in this sluggish stream and have many opportunities of infecting the walls of the vas before they reach the seminal vesicles, where they are stored for a time until finally discharged into the urethra.

The vas may be infected the whole way along, in early cases of its infection this commonly takes place at either end, that is within an inch or two of the epididymis or near its termination in the seminal vesicle; the cord between these two points may be quite normal, and so lead one to suppose that as the cord is healthy above a tubercular testicle therefore the disease has not extended up along the vas deferens.

In February, 1905, I saw a young gentleman, who had had one testicle removed for tubercular mischief about two years before, the second testicle now had a similar deposit, the cord felt quite normal, and we hoped to be able to curette away the disease and save the testicle if there were no sign of infection spreading up to the seminal vesicles; even after the cord was exposed with its veins the vas felt normal, but the testicle was found to be too far involved to save it, and it was in consequence removed, the vas being separated from the rest of the cord at the same time. It then became apparent that the vas was not healthy, two minute nodules were situated in its wall about an inch above the testicle, as much as possible of the cord was removed, and inside the abdomen two more small nodes were found on the vas; rectal examination showed no sign of infection of the prostate or seminal vesicles, but I fear that this may occur later on.

The disease often attacks the second testicle, and from here it may extend backwards along the cord to the seminal vesicle on the same side; or the reverse may occur, the second vesicle being infected from the first vesicle or the prostate and from this the tubercle spreading to the testicle against the direction of the seminal flow. That infection can go in this direction we all know from cases, that are not uncommon, of sepsis spreading from the posterior urethra to the epididymis.

The age at which tubercle shows itself in the epididymis is from about 16 to 24, seldom after this, though deposits sometimes occur in infants.

The cause—injury is the most commonly assigned cause, where any cause at all is given, I think that a form of what I might almost call chronic injury is not without importance—I refer to masturbation. This is an unsavoury subject to discuss, and for this reason is ignored to a greater extent by more surgeons than it deserves to be. So often in taking the histories of

(a) Being a paper read before the Surgical Section of the Royal Academy of Medicine in Ireland, December 1st, 1905.

severe cases of genito-urinary tuberculosis have I learned that the patient was a masturbator, and continued the practice after the first appearance of the disease, that I feel confident that masturbation has a direct bearing both on the causation and the spread of tuberculosis of the genital tract. Where only one testicle is affected, as a rule the surgeon will not hesitate to remove the disease; in all probability to do this completely will necessitate the removal of the testicle. This loss is not a serious one from the patient's point of view, and the operation is often attended with the most satisfactory results. Sometimes this is not so, and later on the disease appears in the second testicle, or when the patient first presents himself both the testicles may be already infected. Under these circumstances general antitubercular treatment may be used, a partial operation may be done, *i.e.*, the disease scraped away as completely as possible, or a complete operation may be done and both testicles removed. Castration is a very serious operation from the patient's point of view, and unless his surgeon can promise him almost certain success as the result of the operation he will hardly submit to it, even though the testicles themselves are functionless. I have already called your attention to the fact that early in the course of the disease, be it in testis or epididymis, the function of the testicle is lost, it is, under these circumstances, useless to a patient and a source of danger to him. If the disease has extended to the prostate, seminal vesicles or bladder, there is not much use in removing the testes and hoping that this may check the disease—for such hopes are not likely to be realized. This procedure has been often recommended, but I do not think that it ever stops the advance of the disease; indeed, I believe that it has the quite opposite effect, that in reality it lessens the resisting power of the prostate and vesicles to withstand the advances of the tubercle, for the removal of the testes leads to a gradual atrophy of these organs, and with this atrophy there will in all probability be a diminished power of resistance to disease.

Can the extent to which the disease has spread be definitely made out?—In most cases it can, if the urine be clear, if the bladder holds 12 to 14 ozs. without pain, if there is no frequency in all probability the bladder is not infected.

Still, infection of the bladder sometimes occurs as submucous tubercles which may give rise to no symptoms; they can be readily seen through a cystoscope, and it is as well in all such suspected cases to examine the bladder by this means.

Infection of the seminal vesicles and prostate may give rise to similar symptoms to those of bladder infection, and here again it is advisable to make a cystoscopic examination. On the other hand, I have seen several cases of infection of both prostate and vesicles in which there were no symptoms beyond a slight feeling of weight in the perinæum, yet on rectal examination extensive disease of these organs could be easily made out.

Nodules in the prostate can be readily felt by the examining finger in the rectum, but the vesicles are harder to reach; fully distending the bladder with from 20 to 30 ozs. of an unirritating antiseptic lotion, and then placing the patient in the knee chest position, will be found of assistance in carrying out this examination.

I next wish to draw your attention to the course which this disease takes when the entire seminal tract is involved. I can best do this by describing three typical cases which have lately passed through my hands.

In August, 1905, I saw a gentleman, æt. 25, he told me that five years before the left testicle became swollen and discharged pus through the scrotum for several months, and then was pronounced well; six months later the other testicle became enlarged, broke, discharged for six weeks, and then healed up. For a year all went well, then an abscess appeared in his right groin, and this abscess has never completely healed up. Four months ago the bladder became involved; there has been increasing distress since then. His

present condition—His urine contains a quantity of pus, blood, and tubercle bacilli, he passes water every ten minutes day and night, pain always present, often very severe. There are tubercular nodules in each epididymis, in the prostate, and both seminal vesicles; the cords feel normal. The bladder is highly inflamed, tubercular ulceration has occurred in several places, the mouths of both ureters are patulous, the disease will almost certainly extend up to the kidneys if it has not already done so.

CASE 2.—A strong-looking man, æt. 28, was admitted to the Adelaide Hospital under my care, in March, 1905. From the age of 16 he has been a confirmed masturbator, at 20 he developed a small nodule in his left testicle; this was treated for some months with applications, and finally ceased to trouble him. Three years later a similar nodule appeared in his right testis; after a time this broke, and finally had to be scraped out. For two years after this he kept well, then the testis broke out again and symptoms of irritation at the neck of the bladder began to show themselves, and pus appeared in the urine; a month before admission he was attacked by a pain in the region of his left kidney, this pain has never since left him. He has great pain passing water; this he has to do every few minutes during the day and about every half hour through the night; the urine is foul, contains a considerable amount of pus, tubercle bacilli are present. There are tubercular deposits in both epididymis, in the right vas, and in both seminal vesicles, the lower end of the left ureter can be felt much enlarged, the left kidney is swollen and tender. The walls of the bladder are inflamed and in places ulcerated, the mouth of the left ureter is wide open, from it pus is coming. The left kidney and ureter are infected in this case.

CASE 3.—A soldier, æt. 26, admitted to hospital under my care in January, 1905. Patient was a confirmed masturbator until about the age of twenty. When 21, while serving in Egypt, a small tubercular nodule developed in his right testicle, it gave him no pain or inconvenience, and was not treated. Two years later while serving in South Africa the other testicle became affected; he was sent into hospital, where the testis was removed. In six weeks he was back on duty again, his health during the whole time being excellent. Two years later bladder symptoms began to come on, pus appeared in the urine, pain became severe, and finally he was invalided from the service. When I saw him his condition was pitiable; the right testicle, vas, both seminal vesicles, and prostate were infected, there was extensive ulceration in the bladder, from the right kidney a quantity of pus was coming, the kidney itself was much enlarged and tender, the left kidney was also painful and the urine coming from it contained pus; the urine was voided every few minutes; it contained numbers of bacteria, and among them tubercle bacilli.

To try and relieve the intense pain in the right kidney I drained it from the loin—it was a mere bag of foul pus; this drainage gave temporary relief. He was moved to the Rest for the Dying, and died there some two months later.

These three cases have many points in common. I could find no sign of tubercular disease outside the genito-urinary tract. In each the deposit in the testicle was, I think, primary; this was followed by the infection of the vesicles, prostate, and remaining testicle at varying intervals. From this the disease spread to the bladder. In case 2 it had reached one kidney; in case 3 it had destroyed the kidneys and finally put an end to years of suffering. I fear that the same fate is in store for cases 1 and 2; treatment may delay, but will hardly prevent a similar termination.

The disease occurred in otherwise healthy young men, who all had surgical advice and the means to carry out the treatment ordered. In the worst case the disease developed while the patient was in Egypt and South Africa, both climates which should have helped to stay its progress. These three patients would have submitted to any operation, no matter what

mutilation it might entail, if it would relieve their pain, even if it did not cure; but beyond draining the kidney in the one case, I did not see that any operative interference was justifiable. I have given these cases in some detail, for they are, I think, typical of their class, and because they have left a vivid picture on my mind of the course and termination of this disease.

Of earlier cases occurring during the past five years, in which both testicles and prostate or seminal vesicles were infected, some I have been unable to trace; but in all those that I have been able to follow, the disease has progressed from the seminal tract to the bladder, and from there has infected some vital organ, eventually causing death. I may have been unfortunate in the cases which have come under my notice; they have compelled me to believe that the ordinary methods of treating this form of the disease, such as open air, dry climate, forced feeding, etc., combined with partial operations, such as scraping away the tubercular deposit from the testicle, are of little avail in checking its course, and offer small hope of cure to the patient.

In January, 1905, a young man, æt. 22, was admitted under my care at the Adelaide. From the age of 15 he had constantly masturbated; he attributed all his troubles to this vice. Three years before his left testicle became swollen and painful. This swelling passed off, leaving a small hard nodule in his epididymis. This nodule gave him no further trouble. Three months before admission his right testicle began to swell up, broke, and pus came away. On admission there is a hard tubercular node in his left epididymis; the vas above this feels normal. On the right side the whole testicle and epididymis is tubercular, a sinus leads to the former from which pus is coming; the vas above feels as thick as a lead pencil right up to the inguinal canal, with a finger in the rectum the vas on the same side can be felt still thickened as it passes into the prostate, the vesicles and prostate itself feel normal. Urine is normal.

Cystoscopic examination of the bladder shows it to be quite healthy. I advised the removal of the right testicle, and, if possible, the whole of the vas. This I tried to do by following up the vas into the inguinal canal, the floor of which I opened, dividing the deep epigastric artery. I could not get the entire vas away through this anterior incision, and left behind about an inch of it. I left in a small drain, but nothing came away, and the wound healed in ten days.

On his discharge from hospital the patient was given orders to report himself to me once a month in case of further infection taking place. He did not come for three months. One end of the wound had opened and was discharging tubercular pus, evidently from the remains of the diseased vas, the remaining testicle and cord showed signs of fresh infection, and tubercular nodules could be felt in the prostate and both seminal vesicles. There was, in fact, active disease of the whole seminal tract. The urine remained normal, the bladder was healthy, but I could see the swollen right vesicle bulging up into the base of the bladder. I felt that the only treatment that offered a reasonable hope of success was the removal of the whole of the disease. The remaining testicle was useless and should be removed; with it should come both cords, vesicles, and prostate, if this could be done without great risk to the patient.

There are three different routes by which the vesicles may be reached—Zuckerkindl's, by a perineal incision; Kraske's, by removing portion of the sacrum pulling the rectum to one side, and so exposing the base of the bladder; and Young's, who by a large T-shaped incision through the lower part of the abdominal wall dividing both recti muscles gets at the bladder in this way. Of these three the first is the simplest and much the least severe operation. I tried this operation several times on the cadaver, but found it exceedingly difficult to reach the vesicles by this method. I looked up some recent works on genito-urinary surgery to see what advice they gave as to the

removal of tubercular seminal vesicles, the information they contained was not altogether encouraging.

Watson Cheyne says, "Some surgeons have performed elaborate operations for the removal of tubercular seminal vesicles before suppurative has taken place. It is doubtful, however, whether an operation of this kind should ever be performed, as it must be very extensive and the affection is usually secondary and therefore does not warrant it."

Lydston says: "Many of the radical operations performed on the prostate and seminal vesicles for malignant or tubercular disease are, in the author's opinion, absolutely unjustifiable. The operator displays brilliancy of technic and boldness of surgical enterprise, but no other ends are conserved."

Taylor says: "In the vast majority of cases, operative treatment is not to be thought of, unless suppurative has occurred in the sac, when its contents must be evacuated through a perineal incision, the cavity cleaned and packed with iodoform gauze. These patients should be sent to a suitable climate and receive the regular treatment for tuberculous subjects."

In spite of these remarks, I still felt that an attempt should be made to remove the disease from my patient. I decided to follow the steps of Young's operation for perineal prostatectomy, hoping by the use of his tractor to bring the vesicles well within reach. I do not intend to describe the steps of the operation, as this was admirably done by Mr. Arthur Ball at this Academy last session, a full account of which appears in last year's *Transactions*. The two dangers I feared were that in separating the adherent seminal vesicle from the bladder I might injure the ureter, the other, that the veins surrounding the vesicles and prostate might cause dangerous hæmorrhage. As a precaution against the second, I gave the patient dram doses of chloride of calcium night and morning for three days before the operation. Whether this had any effect or not I cannot say, but the amount of blood lost during the operation was very slight. I removed the testicle and as much of the cord as I could from the front, then, closing the inguinal wound, I removed through the perinæum the ends of both vasa deferentia, vesiculæ seminales, and the prostate.

I had no great difficulty in separating the upper part of the right vesicle from the ureter, but the portion near the prostate was firmly attached to the bladder wall. Either I used too much force with the tractor or had gone too deeply, for the blade of the instrument perforated the bladder-wall where the vesicle had been attached to it. I made no attempt to close this opening, but passed into the bladder two No. 12 catheters, one through the urethra and the second through the perineal wound, and packed firmly round this perineal drain with iodoform gauze. The gauze plugs were removed on the second day, the perineal tube on the fourth day, the urethral catheter on the seventh day, on the eighth day the patient was allowed up. He had then no difficulty in passing water, perfect control over the bladder, and no leakage from the perineal wound; on two occasions later on some slight leakage occurred from this wound, but did not last for more than a day, and since then the wound kept dry and healed well.

Six months later I examined this case. His bladder was quite healthy, the wound at the side of the trigone was firmly healed, urine normal; no return of the disease can be felt by the rectum; his general health is good. He has put on over a stone weight since his operation. I hope that this case is cured.

In August, 1905, another case of the same kind came under my care, with the exception that he was younger, only æt. 19, and that the one testicle was removed about a year before the disease appeared in the second. The cases were almost the same, and I will not weary you with what would be almost a repetition of the case I have just described to you. The vesicles were not adherent to the same extent and came away without any injury to the bladder wall.

The perineal wound was slower in closing up. The boy was up on the eighth day, and had perfect control

of his bladder from this on; yet for nearly a month there was a slight leakage of urine through the perineal wound every time he passed water. By the end of September he was able to resume his work and has since kept quite well, and is putting on weight. It is much too soon to say there will be no recurrence of the disease in this case, but his condition leads me to hope that he also is cured. The entire operation did not exceed in either case forty-five minutes. This time included the removal of the testicle and cord by an inguinal incision and the prostate and vesicles by the perineal. There was no shock in either case, but each patient received a saline transfusion before he left the operating table.

In conclusion let me recall to you a few important points:—(1) That infection may readily pass along a normal vas to the vesicle or prostate, the fact that the vas above a diseased testis feels healthy is no proof that the tubercle has not extended to the vesicles. (2) That when both testicles and seminal vesicles are infected radical treatment alone is likely to be followed by success. (3) That where the disease is confined to the seminal tract it can be completely removed, and that without any great risk to the patient. (4) That in all probability the patient is functionally no worse after such an operation than he is after a partial operation on both testes.

My thanks are due to Mr. Gordon, who assisted me at the first operation, to Mr. Heuston, who helped me at the second, and also to Professor Dixon for much help and advice in the anatomy of this seminal region.

THE VITALITY OF A NATION.*

By THEO. B. HYSLOP, M.D., M.R.C.P.

(Medical Superintendent of the Bethlem Royal Hospital for the Insane. Lecturer on Mental Diseases, St. Mary's Hospital, Paddington.)

The innate conceit of man renders him apt to claim for himself exemption from the universal laws of evolution and dissolution. It is open to argument, however, that just as living cells, organisms, lower animals, species, and even worlds live and die, so mankind must be subject to the same universal laws.

As the universe is the tomb of dead and dying worlds, so our earth is the tomb of dead empires; and, there is evidence to adduce that there are restrictions to the evolution of humanity in the earth's habitable portions.

Not only do races have their periods of increased virility, vitality, greatness and subsequent dissolution, but the inoculation of a community with a virus—so to speak—which leads to its greatness is followed in due course by diffusion and attenuation, and this confers immunity against further infection or regeneration. This law is exemplified in the history of every decayed race, and, from physical, geographical, ethnological, and psychological considerations, it appears that mankind is not only approaching the summit of attainment, but is also possibly growing old.

The law of antagonism between individuation and genesis, and the law of regression towards mediocrity, hold valid for the restriction of evolution; and it is demonstrable that our acquisitions and attainments, derived as they are from the artifices of civilisation, are not only impediments to true mental evolution, but tend to submerge and render less vital the human mental faculties.

Civilisation brings with it evils which render decay inevitable. Increased wants and enjoyments interfere with the simpler modes of life and the capacity for labour. It introduces new diseases, previously unknown, which on a new soil commit frightful ravages, and, more important still, it stamps and registers the numbers of those who are physically and mentally unfit to reach the standard of efficiency imposed by it.

In view of the immunity against further evolution conferred upon many races which have lived and had their day, and in view of the present rapidity with which interbreeding, overlapping, co-operation, and

mutual help are enabling mankind on the habitable portions of the earth to rise to the higher states of development, it appears warrantable to assume the approach of a crisis in mental evolution with subsequent universal immunity against regeneration.

Our race is so far civilised, or—so to speak—levelled up, that its limitations are becoming more fully exposed to view. Thus, were we to take a census of those who are able by their inherent powers of reasoning or thought to contribute to the further evolution of mind, we would be compelled to confess to indications of retrogression.

Humanity demands survival and accumulation of the unfit, on the assumption that all forms of human life are potentially for the service of God. Civilisation demands retention and accumulation of material possessions for the ease, comfort and benefit of mankind. And individual man demands retention and accumulation of knowledge for the evolution of his mental faculties. In these three demands and their effects we have in reality the chief repelling factors to true development—as distinguished from growth—of the vitality of thought or reason, *per se*.

These considerations lead one to ask, "Do our experimental operations on Nature really aid us to evolve to something greater, or do they but favour dissolution of the greater number?" In the answer to this question lies the highest of all conceptions, viz.—the real path of evolution from brute to God.

As with an individual, so with a nation; certain symptoms may portend a decay which is inevitable. With us, as with other nations which have lived and died, we have known freedom and glory. Wealth, vice, corruption and barbarism are but the sequels.

A remedy is being sought through all classes of our race, but the tendency is to deal with symptoms rather than with the constitutional defects which give them rise. Thus, compulsory education has been devised for ignorance and vice; free education and free food for pauperism; *creches* for parental irresponsibility; innumerable methods of caring for the aged to remedy filial irresponsibility; and so on until we have come to see within measurable distance the fostering of maternal irresponsibility by municipal free milk supply for infants, &c., &c. Thus we witness an age which may be termed the "splint age," inasmuch as we apply philanthropic anodynes, splints and poultices which either make or mask symptoms which are already, or soon become, evidences of constitutional importance.

The role of alcohol in the production of decay is as potent with a nation as with an individual. At the present time, however, there exists an active wave of common sense with regard to the consumption of substances which are harmful both to the individual and to the nation, and, whilst recognising that, although much has been done already, it behoves us all to put forth increased efforts to tackle each and every individual unit, and thereby subscribe as best we may to an amelioration of one of the factors which tends to make our empire drift into premature senility and an early grave, when it is yet capable of vigorous evolution and a further amplification of its share in the boundless stores of nature.

SEXUAL PERVERTS.

By ROBT. R. RENTOUL, M.D., M.R.C.S.ENG.

In the MEDICAL PRESS of December 27th, a very instructive case is referred to where this month a man was sentenced to penal servitude for life for a sexual offence. He had been sentenced twenty-nine years ago for a similar offence with penal servitude for life. After serving fifteen years he was released. Soon after he was again sentenced for two years with hard labour.

Max Nordau says that sexual perversion has the same insatiable desire upon the erotomaniac as has alcohol upon the dipsomaniac. If this be so—and I know of no one having questioned it—surely it is time that medical practitioners looked more closely into this

*Abstract of paper introducing a discussion before the Society for the Study of Inebriety, January 9th, 1906.

sad disease. The sexual pervert is a fairly common person. It is difficult to believe that any sane man will prefer morbid sexual acts when there are so many prostitutes willing—nay anxious—to oblige him by a fee ranging from a few coppers upwards. Last December, at the Liverpool Assizes, a man was sentenced to 25 years' penal servitude. For what? For criminally assaulting a baby five weeks old! I took some interest in this case, and found out that the man had been in the army in India, that he had had a severe sunstroke, that he had been dismissed, and that his mother was in an asylum. Now, what is the use of treating this poor sexual pervert—this sad product of our civilisation—as if he were a criminal, and responsible for his actions? There is neither justice, law, nor pathology in such punishment. There are thousands of cases of this kind in our country. Why do we not study the causes as we would study the causes of plague, typhoid, or yellow fever? If they are diseased conditions, why not study them?

I have, at considerable time and expense, collected the following statistics, and I think their perusal will teach practitioners—medical and legal—to honestly study these sad derelicts. The statistics are for one year only, and relate to persons convicted at Assizes, Quarter Sessions, and Courts of Summary Jurisdiction in the United Kingdom, 1902:—

	No. Tried.	No. Convicted.
Unnatural offences	33	31
Attempt to commit unnatural offences	58	33
Indecency in males	72	42
Rape	197	97
Indecent assault on females ...	621	420
Defilement of girls under 13 yrs.	114	82
Defilement of girls under 16 yrs.	179	83
Indecent exposure	2,000	1,741
Prostitution	14,907	12,356
Incest	14	1
Lewd and libidinous practices...	65	54
Procuration	43	28
Indecent advertisements	94	83
Brothel keeping	1,349	1,173
	19,746	16,204

It is to be noted that the above are only those who have been brought to the notice of the police. Is it too much to suppose that at least four times this number of cases take place? It would be most instructive to find out the number of times each sexual pervert was punished for the same offence. At present I am engaged in trying to find out. It took many years for us to find out that "Jane Cakebread" was not accountable for her actions, and for this reason I think this poor dipsomaniac deserves a public memorial. She taught us much, and may, I think, be described as the actual founder of all our legislation relating to inebriety and inebriate asylums. Lately I have been told of the sad case of an old man who has been sent to prison for the thirtieth time for indecent assaults on children. Does any man—any honest man—suggest that this person is not a sexual degenerate?

We have a large number of such degenerates at present in our prisons, where they are kept at the expense of the already overtaxed taxpayer. Is it too much to ask that these persons shall be sterilized by the operation which I have suggested for this class of degenerates—i.e., division and ligation of their spermatic cords (spermeotomy).* If it be right to remove the ovaries for a physical disease of these organs, or to remove the healthy ovaries for a distant disease—such as mollities and ossium fibroids, or deformed pelvis—surely it is equally right to treat these poor sufferers, and relieve them of the cause of their diseased actions. I have no sympathy with those who taboo such degenerates. Medical science is, or should be, above cant and cowardice. It purifies everything, because it is seeking after truth. Both the doctor and the night soil's

man have to tackle unpleasant work; but this is no reason why the work should be left undone. If we know that these perverts are a result of disease, surely they have a right to claim our earnest attention. If we neglect them we fail—through contemptible cowardice—to do our duty to a diseased portion of humanity, a portion who are not often diseased because of their own action, but because they are frequently the products of mentally diseased parents.

CLINICAL RECORDS.

TRACHEOTOMY AND REMOVAL OF HALF OF THYROID CARTILAGE FOR SYPHILITIC LARYNGEAL STENOSIS.

By FITZGERALD POWELL, M.D. St. And.,
F.R.C.S.Ed., (a).

Surgeon, Hospital for Diseases of the Throat, Golden Square, London, W.

IN a male, æt. 34. Police Inspector (India).

Previous History.—Fourteen years ago attended Golden Square Hospital with ulceration of larynx. He states he had a chance four years ago. Was admitted to Penang Hospital March 10th, 1904, and tracheotomy was performed there on April 1st, 1904, on account of urgent dyspnoea, previous examination of the larynx having been unsuccessful. The dyspnoea was increased by pot. iodi.

On admission to Golden Square Hospital, June 13th, 1904, he was wearing a Parke's tracheotomy tube. The right vocal cord was fixed. The left freely movable. There was considerable swelling of right ventricular band. The right arytenoid was immovable. A white-looking mass was seen below the cords. There was considerable stenosis of the glottic aperture.

June 19th.—He can breathe fairly easily for about twenty minutes with the tube corked, and if a hole is bored in the cork, can breathe for hours. Taking potass. iodi. 20 grs.; liq. hyd. perchlor. 1 drachm, t.d.s., with inunctions of mercury.

July 2nd.—The tracheotomy wound was enlarged upwards, and the white mass removed, and found to be part of thyroid or cricoid cartilage, which had necrosed the sequestrum lying above the tracheotomy tube.

April 16th, 1905.—He was re-admitted to hospital. Can breathe for sixteen hours with tube corked. Has been taking iodide and mercury since he left hospital in July. Patient was very anxious to have tracheotomy tube removed, as his appointment depended on his being able to speak without the tube. He urged operation.

April 15th, 1905.—I removed the tube and inserted a Hahn's canula, through which he had chloroform administered. I split the thyroid cartilage longitudinally, and removed practically the whole right side of the larynx, right arytenoid cartilage, ventricular band, vocal cord, part of thyroid and cricoid cartilages, stitched up the wound and introduced a silver dilator above and resting on the Hahn's canula.

April 16th.—Removed Hahn's canula. Durham's T tube inserted with dilator still in. Increasing sizes of these dilators were worn for over five months to keep open and enlarge the glottic aperture.

September 15th, 1905.—The tracheotomy tube was removed altogether.

December 1905.—Is now breathing quite well, and comfortably. Not the slightest evidence of any tendency to closure or contraction of the glottic opening. Small fistula in region of old tracheotomy wound is healing up. Voice fairly good and improving.

Larynx, the mucous membrane is healthy. Left vocal cord moves quite freely, and there is good room in the larynx. Patient in excellent health.

* Proposed sterilisation of certain mental degenerates, 1933.

(a) Clinical case shown at the Association of Diplomates of Scotland Meeting, 11, Chandos Street, London, W., December 12th, 1905.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Case of Necrosis of Jaw.

Under the care of PEYTON BEALE, F.R.C.S.

AMONGST the surgical cases in the out-patient room, Mr. Peyton Beale drew attention to a case of Necrosis of Jaw, in a man, æt. about 25, who was employed in a brass foundry. The patient had noticed about five months previously that his incisor teeth of the lower jaw were becoming loose and painful; his gums were also tender and spongy, then the gums surrounding these teeth began to ulcerate and he had the whole of the lower incisors removed. The ulceration of the gums extended, and when he applied for treatment the whole of the front of the lower jaw was bare nearly down to the meatal process but the bone was not in any way loose. Mr. Beale believed that the condition was caused by the fumes of zinc being inhaled, while the molten brass was being run into the moulds for the purpose of making castings. This would account for the gingivitis and the loosening of the teeth; the probability was that septic organisms thus gained access to the sockets of the loosened teeth and to the periosteum of the lower jaw; the septic process then spread downwards in front of and through the bone, causing it and the tissues in front of it to necrose. In treating such a case one might at once remove the necrosed bone, but he considered this procedure to be very undesirable because (1) it was impossible to say how far the necrosis had really extended particularly as regards the thickness of the bone; (2) the parts were necessarily highly septic and in dividing the bone there was a certainty of infecting tissues which were hitherto free from infection. He considered the best line of treatment to consist in cleansing the mouth as far as possible by the use of a tooth brush and a 1 in 20 solution of Lysoform, which he had found to be the most desirable antiseptic for use in the mouth. The necrosed bone would then gradually separate and in the course of a few weeks would be found quite loose and capable of being picked out bodily. The resulting deformity was very much less than it would be if the bone were removed before a natural line of demarcation had been formed. He had come across three or four similar cases and they were very like the necrosis produced by phosphorus poisoning. As regards the gingivitis the internal administration of iron and arsenic seemed to be beneficial, but it was a noticeable fact that it was very difficult to stop the inflammation owing to the difficulty of procuring asepsis in the mouth. He believed the actual necrosis was entirely a septic process, the primary ulceration of the soft parts only being caused by the fumes from the molten metal. It was of course necessary that the man should not continue with the same work.

Chronic Abscess in the Chest Wall.

A boy, æt. 12, complained of a swelling about the size of a tangerine orange resting upon, and apparently connected with, the fifth and sixth ribs on the left side. There was very distinct fluctuation in the swelling; it was quite painless, had been forming gradually for about four months, and there was no cause to account for its presence. The swelling was at the junction of the cartilage of the ribs and Mr. Beale had no difficulty in deciding that it was a chronic abscess. He pointed out the importance of thoroughly examining a patient and said that a kind of general rule which he always made was to bear in mind the superficial lymphatic glands nearest to the tumour or spot at which the patient complained of swelling or pain; then one should examine the whole of the area which was drained by these glands; if such a rule as this were always borne in mind and acted upon it insured against the possibility of missing some neighbouring abnormality which might be or might have been the primary cause of the trouble for which the patient presented himself. In this particular case, such an abscess was either the result of local tuberculosis of a rib close to its junction

with the cartilage or it was a collection of pus which had tracked along one or more ribs originally starting from tuberculous disease of a dorsal vertebra. Some of these cases were undoubtedly broken down gummata, but as regards the chest by far the commonest situation for a gumma were the sterno clavicular joint and the sternum itself at the junctions of its various parts. He had observed that in the surgical examination of candidates cases like the one under consideration were often presented, and of course it would be necessary to turn the patient over and examine the spine; he had seen many candidates come to grief in clinical surgery through neglecting to do this, but if they would only remember the general rule above quoted regarding the extent to which the patient should be stripped and examined they would not fall into any trap laid by the examiner. When such an abscess was due to local tuberculous disease of the rib the site of disease curiously enough, he pointed out, was always on the inner or pleural aspect. Bearing this in mind the only proper treatment of such cases was to expose the rib and excise the diseased portion bodily. He said that it did not follow that the disease was at the site of the abscess, but when the abscess was opened a bent probe could be inserted and would travel to the position of the mischief, though it was often difficult to find the track as it was on the pleural aspect of the rib.

OPERATING THEATRES.

ST. PETER'S HOSPITAL.

ENUCLEATION OF THE PROSTATE. — MR. SWINFORD EDWARDS operated on an old man æt. 73, who had suffered with difficulty in micturition for the past seven years. Latterly he had been entirely dependent on the catheter. On admission ten days previously, there was some cystitis, but this had been relieved by daily washings. His urine had now a specific gravity of 1012, was acid in reaction and contained but a slight amount of albumen and a little mucus. Examination per rectum revealed a prostate which was elastic and fairly moveable, of about the size of a large tangerine orange. The prostatic urethra was evidently much elongated as a catheter had to be passed in nearly up to the hilt before the water could be drawn off. As this seemed a very favourable case for enucleation, Mr. Edwards proceeded to perform the operation as follows:—A Coude catheter was first passed and the bladder well washed out with boracic solution; it was then filled with sixteen ounces of the same solution and the abdominal wall opened in the supra pubic region through the fibres of the rectus. The soft parts were stripped off the anterior bladder wall upwards by the finger. Before incising the bladder wall, it was inspected, in order if possible to avoid the large veins which often ramify on this surface; in this case it was found possible so to do. Whilst the fluid was escaping through the incision the left forefinger was introduced and the intra-vesical portion of the prostate carefully examined. Mr. Edwards now inserted a special prostatome which he had devised and had made for the purpose, and which he was now using for the first time. By means of this instrument, he incised the mucous membrane over the projecting lateral lobes of the prostate, dividing the mucous membrane in two separate places. The prostatome having been laid aside the right index finger was inserted into the bladder whilst the index and middle finger of the left hand were introduced into the rectum, pressing the prostate well up towards the wound. With the right index the mucous membrane was stripped off the prostate, which was gradually shelled out of its bed

from behind forwards. After about four minutes spent in this process of stripping the gland became free in the bladder, and was delivered by means of lithotomy forceps; but before its complete delivery could take place a small piece of urethra was cut through close to the prostate. The prostate came out whole and apparently weighed from three to three and a half ounces. A one-inch rubber tube was now inserted into the bladder and irrigation with hot boracic solution (temp. 110) was carried out by means of a catheter passed through the urethra. The catheter was next withdrawn, and the supra-pubic drain fixed by a suture in situ. A couple of silkworm gut sutures sufficed to bring the rest of the wound together. There was about the ordinary amount of bleeding, which had nearly ceased by the time the dressings were applied. The enucleation itself only took between four and five minutes, the whole operation not having lasted more than a quarter of an hour. Mr. Edwards said that enucleation of the prostate in fit cases was one of the most satisfactory operations in surgery. This he looked upon as a favourable case, for the prostate was large, elastic and movable as ascertained before the operation by bi-manual manipulation. In this case the intra-vesical portion formed a collar-like enlargement with a small so-called third lobe posteriorly but the enlargement towards the bladder was not as marked as he had anticipated. In this case, he pointed out, he used a prostatome, or knife, which resembled a small straight and narrow periosteal elevator, having a rounded and shallow cutting edge at the extreme end, which he had devised for the purpose of dividing the mucous membrane over the projecting prostate instead of scratching through with the finger nail. On former occasions he had found that the necessary manipulations tended to tire the finger before the actual stripping process began. By this means he hoped to conserve the muscular force of the operator till it was really needed, for the actual stripping process. Mr. Edwards expressed himself as much satisfied with the facility with which the instrument enabled him to carry out this object. In several previous cases he had resorted to the Trendelenburg position in order that after having opened the bladder, he might incise the mucous membrane under the guidance of the eye, but he had found that in some cases even this position together with full retraction of the bladder walls did not always give a good view of the prostate tucked up as it is under the pubic arch; moreover, the time spent in carrying out an enucleation by the latter method is considerably longer and therefore is likely to add to the gravity of the operation.

ROYAL EAR HOSPITAL.

EPITHELIOMA OF THE PINNA.—MR. MACLEOD YEARSLEY operated on a man, æt. 52, a porter at Covent Garden market, who had been admitted suffering from epithelioma of the left auricle. The history was as follows:—Two months ago the patient noticed a small growth about the size of a large shot in the fossa of the anti-helix. This grew fairly rapidly, and commenced to ulcerate one month afterwards. On admission the growth was a little larger than a sixpence, raised, very hard, and excavated by ulceration, the ulcer being distinctly crateriform. There was no glandular enlargement. The patient's urine was loaded with sugar. The external auditory meatus having been packed with gauze, Mr. Yearsley removed the whole auricle, with the exception of the lobule. Commen-

cing in the concha, he took a small semilunar flap from that region, and carried the incision upwards, round the attachment of the helix, and backwards to the posterior aspect of the concha, where he made a second curved flap, ending at the attachment of the lobule behind. The extremities of the incision were joined by a straight cut, dividing the lobule from the rest of the pinna, and the latter was dissected away completely. About four small arteries required ligation. The wound was then sutured in its entirety, the two flaps being brought together above, and stitched to the lobule below. Fresh packing was put in the meatus and the wound dressed. Mr. Yearsley said that these growths of the auricle were not common. Such a neoplasm as that just operated upon probably arose as a primary growth, and from its appearances and history was in all probability an epithelioma. Occasionally, he said, one met with sebaceous cysts in this locality, which sometimes became epitheliomatous. This case, however, he thought was not one of these. Differential diagnosis had to be made from primary chancre and gumma, both of which were rare in this region, and would have been accompanied by definite specific signs and history. The prognosis of a case like this was, he considered, decidedly favourable; the short history, the absence of glandular enlargement, and the slow progress of epitheliomata of the pinna combined to make one hope that a complete operation would not be followed by recurrence. Glandular involvement in these cases was always slow, and when it did occur usually affected the mastoid gland and the occipital group. The fact that the patient had diabetes, he pointed out, probably influenced the prognosis, but the influence one way or the other would, he thought, be known in twenty-four hours.

Instruction in Military Surgery for Civilian Practitioners.

MANY members of the West London Medico-Chirurgical Society having expressed a wish for instruction in the special work of military surgeons so that they may be in a position to render aid in time of war, the Director-General has arranged for a short course of lectures and demonstrations to be given at the West London Hospital on alternate Saturdays at 4 p.m., commencing January 20th. An endeavour will be made to give a broad and practical view of the subject without going too much into detail. Medical men residing in West London, whether members of the Society or not, who may wish to attend the course, which is free, are requested to apply by letter to W. H. Chambers, Esq., 101, Goldhawk Road, W. The course is under the direction of Col. James, Superintendent of the Royal Army Medical College, and the size of the class will necessarily be limited.

The London School of Tropical Medicine.

THE following is a list of candidates who passed the examinations during December, 1905:—Dr. J. M. Collins, Dr. H. M. Sauzier, Dr. J. C. S. McDouall (Colonial Service), with distinction; Surgeon E. R. Whitmore (U.S. Army), with distinction; Dr. J. W. Arthur, Capt. J. Booth-Clarkson (Natal Medical Corps), Dr. H. L. Burgess (Colonial Service); Dr. H. Carlaw (Colonial Service), Dr. R. Cope (Colonial Service), Dr. R. Denman (Colonial Service), Dr. A. C. Falkiner, Dr. J. D. Finlay (Colonial Service), Lieut. C. W. Holden R.A.M.C., Miss J. Hogg, M.B., Capt. T. C. Lauder, R.A.M.C., Dr. E. C. Lindsey (Colonial Service), Dr. M. Ramsay (Colonial Service), Dr. A. R. Rendle (Colonial Service), Dr. A. C. Rendle (Colonial Service), Dr. L. Sells, Dr. R. Small (Colonial Service), Dr. A. J. T. Swann (Colonial Service), Miss F. M. Wakefield, M.B., Dr. P. Wykesmith (Colonial Service).

TRANSACTIONS OF SOCIETIES.

ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND.

CLINICAL EVENING, MEDICAL SOCIETY'S ROOMS, LONDON, W., DECEMBER 12TH, 1905.

The President, CLAUDE ST. AUBYN FARRER, in the Chair.

DR. ALEXANDER MORISON showed a man, who had served as a cavalry soldier in the late Boer war, who was the subject of parasitic hæmaturia. After having bathed in the Blood River (!) he and eight of his companions developed bilharzia hæmaturia. The patient had painful micturition, and the blood was at times sufficient to clot. Dr. Morison exhibited the causal ova of the parasite under the microscope.

DIAGNOSIS BY TUBERCULIN.

DR. DAVID WALSH showed a man æt. 59, a waiter, with a sharply circumscribed, spreading eruption, at margin of anus and buttock, of three years' duration. Had good health up to 1895, when he developed rectal abscess, which was operated upon and followed by fistula. In 1900 he had double pleurisy and a year later the fistula was successfully operated upon. Soon afterwards a reddish slightly elevated eruption appeared near the anus and has grown slowly ever since until it is now 5½ inches in diameter. There is no history of syphilis, and no evidence of lung disease or other trouble. It was determined to inject tuberculin (O.R.) as a test. Accordingly, .001 c.c. tuberculin (O.R.) was administered subcutaneously. There was no rise in temperature, but as the patient's temperature on admission was 98.8 a slight rise might have been masked. Next day .002 tuberculin was followed by a sharp rise to 100 deg., which was maintained for a day, when it fell to 98. A third injection on the fourth day of .003 was followed by a rise to 99. At the second injection the eruption became redder and during the next few days became scaly.

This case is interesting as showing the invasion of skin by infection through an operative wound (assuming that the fistula and the pleurisy were of tubercular origin.) It also illustrates the value of the tuberculin test where any doubt exists as to diagnosis. From its site and appearance the eruption in this case might have been syphilitic.

MR. SYDNEY STEPHENSON showed the following cases, some of them being of extreme interest:—(1) A new sign of mercurial intoxication; (2) congenital lipo-dermoid tumour of the conjunctiva; (3) a case of tubercle of the lacrymal sac.; (4) a case of exophthalmos.

DR. S. LIGHTFOOT showed a case of Raynaud's disease, in which three fingers had been removed by the Bilton-Pollard method. (This case was fully reported, with an illustration, in our issue of Jan. 3rd.)

DR. FITZGERALD POWELL showed a man with removal of half the larynx for syphilitic stenosis. (This case is reported in another part of present issue. See p. 40.) Dr. Powell also showed a typical acute rheumatic pharyngitis, and angioma of palate, fauces and tongue in a male, æt. 34. This patient came for treatment for his ear. He was found to be suffering from chronic suppurative otitis media of both ears, and mastoiditis. The radical mastoid operation was performed on him on October 4th, 1905, and much diseased bone was removed on left side. He is making a good recovery. He was seen to have a large angioma of the tongue, soft palate, and fauces, mostly on left side; he says it does not cause him any trouble. His speech is thick, but he has no bleeding from it. The case is interesting from the great extent of the angioma. Great difficulty was experienced in giving him the anæsthetic at the operation, as the angioma filled and

swelled greatly, interfering with his respiration. The patient declines any treatment for the angioma.

The PRESIDENT (Dr. Farrer) showed a patient with a flail-like and atrophied right leg, in which the knee had been excised.

DR. G. W. F. MACNAUGHTON showed a man, A.P., æt. 21, a silk mercer with light duties. Face pale and somewhat anxious-looking; veins of the upper extremities engorged, the thorax has a left-sided appearance, owing to bulging of the præcordia. The maximum cardiac impact is in the sixth left interspace, in a line with the nipple. Epigastric pulsation is present, denoting in this instance enlargement of the heart. Its sounds, on auscultation, indicate hypertrophy, while there is arhythmia. Patient came complaining of cough and pain and uneasiness in the infra-axillary and sub-scapular regions on the left side. There is a slight sulcus or shallow depression, corresponding to the attachment of the diaphragm in front. No history of rickets, rheumatism, of depraved habits, or of excessive muscular efforts, and Dr. Macnaughton believed the enlargement of the heart to be due to early disciplinary singing. The rules of voice production and their frequent practice at an early time of life, when the organs are sensitive and growing, implying as they do a physical and nervous strain, are the cause of enlargement of the heart, of which this is an example. The administration of arsenic here is the most useful means of aiding this condition, with, needless to say, the cessation of singing, although when once this hypertrophy of the heart is produced, it persists to a greater or lesser degree throughout life.

RECKLINGHAUSER'S DISEASE.

DR. P. H. PARSONS showed a case of congenital multiple neurofibromata in a man, æt. 39. (This case we hope to report fully in our next issue, together with an illustration.)

DR. H. MACCORMAC demonstrated some curved needles with handles (one piece of metal) for abdominal operations.

LIVERPOOL MEDICAL INSTITUTION.

A MEETING HELD DECEMBER 21ST, 1905.

SIR JAMES BARR, the President, in the Chair.

A NUMBER of clinical cases were exhibited, and later Dr. R. J. M. BUCHANAN and Dr. C. J. MACALISTER, opened a discussion

"IS THE SANATORIUM TREATMENT OF CONSUMPTION WORTH WHILE?"

DR. BUCHANAN said that in consumption, as in other infective processes, some internal power is working towards recovery; and much may be done by stimulating this power to action or in assisting it when inactive. In all cases of phthisis, especially in the early stages, treatment is urgently called for, and is usually followed by marked benefit. He pointed out the principles upon which the treatment of consumption should be based, and said these are indicated by our knowledge of otological factors; and the principles of hygienic and dietetic treatment, which are true, honest, sensible, and right, and demand the advocacy of all true, honest, sensible, and right-minded members of the medical profession. These principles of treatment admit of no discussion, and are best carried out in a sanatorium worthy the name, by a medical man who thoroughly believes in and enforces them in a systematic and exact manner, with the due amount of respect which their truth demands. Dr. Buchanan's personal experience of sanatorium treatment enabled him to say that he knows of no treatment so invigorating, so sensible and so trustworthy, and which holds out so much hope and encouragement, or which affords so great a prospect of success.

Dr. MACALISTER said his experience of Sanatorium treatment had been disappointing, for although many of the cases had been sent in the early stages of the disease, in nearly every instance a relapse had subsequently occurred. He commented upon the utter futility of treating the poor in sanatoria, and pointed out that those patients who subsequently die from phthisis, do so in much the same period as they would have done, had they never been in one of these institutions. The death-rate from phthisis had not diminished to any great extent since the advent of the sanatorium treatment, and judging from the figures of those who kept careful records in the pre-sanatorium days, the recovery rate and the death-rate of the disease was about the same as it is in patients treated in sanatoria. Dr. Macalister thought that many of the most successful sanatorium cases represented patients in whom a strong tendency to recovery existed; and mentioned his experience with patients presenting this tendency. He thought the personal factor had more to do with recovery than any special line of treatment. He advocated the construction of inexpensive buildings for sanatoria, so that more money might be devoted to the maintenance of a larger number of cases both early and more advanced. He thought the best way of dealing with the problem was to endeavour to prevent the disease by exercising much stringency, with reference to known elements of infection, and by adequate disinfection of dwellings inhabited by persons suffering from phthisis.

Mr. COLIN CAMPBELL thought it unfortunate that after ten or twelve years of sanatorium treatment, facts remained so few, and statistics so inconclusive or contradictory. The utmost confusion still existed as regards the classification of cases, and vagueness in the reports of the various forms of cures, so called, obtained. Favourable results lie somewhere between the 60 per cent. of "economic cures," reported from Germany, and three out of 38 reported from Heswall, in which the disease was "arrested."

Dr. G. A. GRACE-CALVERT said statistics of sanatoria results are adversely affected by the very short stay many patients make—often six weeks or less, by the kind of work to which a patient has to return, and by the surroundings, often the most unsuitable, to which patients return. He emphasised the necessity of sending early cases to the Sanatorium; for the great majority did excellently, and it was wise to send such patients to the Sanatorium first and to the country afterwards, because they then early learn how to carry out treatment and much valuable time was saved.

Dr. ERNEST NEVINS considered that as Poor-law authorities and other public bodies were being urged to erect sanatoria, the phrase "worth while" should be judged from the point of view of social economy, in which case the decision would be unfavourable. Many sanatorium enthusiasts had admitted that results were unsatisfactory, but the blame was thrown on the patients who were "unsuitable." The conditions necessary to make a case "suitable" were impossible for the vast majority of consumptives, and it was little or no use teaching a man a mode of life which his social circumstances would never allow him to carry out.

Dr. W. B. H. Wood, Dr. T. R. Glynn, Dr. A. L. Morgan, Dr. W. B. Warrington, Dr. Nathan Raw, Dr. A. G. Gullan, Dr. E. T. Davies, and the President also took part in the discussion.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 4TH, 1906.

MR. C. E. HUTT, President, in the Chair.

THE following cases were exhibited:—

Mr. WALTER EDMUNDS showed (1) a man, *æt.* 19, with a loose body in the right knee-joint. There was a history of injury two years previously, but the

feeling of weakness and of the limb "giving way under him" had only been present for the last six months. There was some creaking on movement of the joint. (2) A man with a peculiar warty growth of the lower lip.

Dr. A. J. WHITING showed (1) a man, *æt.* 49, with an aortic aneurysm, affecting the first part of the aortic arch, who had been treated with six gelatine injections. The swelling, which was palpable externally to the right of the sternum had diminished in size from that of a tangerine orange to that of a large walnut.

Mr. EDMUNDS, while acknowledging the fact of the diminution in size of the aneurysm, considered that no aneurysmal dilatation of a vessel could be really cured unless the vessel upon which it was, was at the same time occluded. In the present case the swelling still presented expansile pulsation, showing that some of the contents, at any rate, were fluid. (2) A man, *æt.* 37, the subject of phthisis in whom subcutaneous emphysema had occurred.

Dr. G. P. CHAPPEL showed a girl of ten with empyema presenting many of the features of bronchiectasis. The child had had a cough for two years, but there had never been any acute attack of pain or fever. The whole of the left side of the thorax was dull, but the heart was drawn over to the affected side. During the last month the dullness had somewhat diminished. The general appearance of the patient was healthy.

Dr. J. HUNT recalled a case of empyema he had seen on the point of perforating externally which subsequently turned out to be a typical cirrhosis of the lung.

Dr. F. H. WALLACE pointed out that there was a definite shadow in the present case seen upon examination with the X-rays, which moved with the position of the patient.

Dr. E. HOOPER MAY remarked that competent observers had shown that little reliance could be placed upon the shifting character of the dullness in the diagnosis of empyema.

Two cases of cretinism were exhibited by Dr. J. M. LAUGHTON and one by Dr. R. BROWN.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of this Society was held on Friday, January 5th, 1906. In the absence of the President, Dr. G. P. SHUTER took the chair and referred in feeling terms to the irreparable loss that the Society had sustained by the sudden death of Dr. Campbell Pope, one of its original members.

The following cases were then shown by Dr. BONTOR, a case apparently of Pernicious Anæmia, which had much improved under treatment, which consisted mainly of increasing doses of Arsenic and Salol. By Mr. KEETLEY, a case of Ruptured Quadriceps Extensor Cruris in an old man treated by suture; and also a kidney which had been removed from a young lady, for hæmorrhage due to a crushing of the organ which had been completely torn into two parts. The patient made a satisfactory recovery. By Dr. SEYMOUR TAYLOR, a case of probable Gumma of the Pons Varolii. By Dr. PHINEAS ABRAHAMS, an unusual case of Lupus Erythematosus. By Dr. LEONARD DOBSON a case of Lupus, which after being very obstinate to treatment by scraping and X-rays, had been much improved by kataphoresis. By Dr. ARTHUR SAUNDERS a case of Progressive Muscular Atrophy, and also one of Rickets with an unusual form of deformity of the arms. By Mr. ESTLETT BALDWIN, a case of congenital elevation of the Scapula. By Dr. Andrew ELLIOTT a case of Embolism of the Arteria Centralis Retinæ. By Dr. GARRY SIMPSON, a case of Congenital Ichthyosis.

An interesting discussion followed the exhibition of most of the cases, and a large number of members took part.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS
ABROAD.

Paris, January 8th, 1906.

PNEUMONIA IN CHILDREN.

As everyone knows, pneumonia is very frequent in children over two or three years of age. The cortege of accidents attending the development of infantile pneumonia is very alarming for the parents and sometimes puzzling for the attending physician, as frequently the diagnosis is obscure and difficult where the temperature oscillates between 98 deg. and 104 deg.; where after five or six days it falls to the normal, leading to the belief of definite defervescence, yet the same evening the fever runs up again to 104 and so on throughout the malady.

Generally speaking, the diagnosis of pneumonia is as easy in the adult as it is difficult in children. In the adult the debut is sudden, rigor, pain in the side, vomiting, cough with characteristic expectoration, dyspnoea, fever, physical signs easy to detect, and finally the information the patient furnishes himself. There is hardly one of these symptoms, says Prof. Variot which may not be wanting in a child, especially if he be under four years of age. Has he had a rigor? Who can tell? The pain in the side is habitually absent, as the dyspnoea and acceleration of the breathing are far from being as frequent as in the adult. Generally, the children of five or six localise the pain in the abdomen, and above all in the right iliac fossa. When this abdominal pain coincides with vomiting and high fever it may suggest to the physician troubles of the appendix.

Dyspnoea is generally constant in the adult; the respiratory movements are precipitated, laborious and painful. In children it is frequently absent as a pathognomic symptom, for the number of the respirations which may amount to 30 or 40 in the minute can be observed in other febrile affections. In bronchopneumonia, on the other hand, the dyspnoea is constant, constituting a good differential sign between it and pneumonia proper. The cough during the first three or four days is slight and attracts little attention; it is rather towards the end of the malady that it becomes frequent.

As to expectoration, it is one of the most characteristic signs of pneumonia in the adult; by it alone, when it consists of rusty coloured sputa, the diagnosis can be established. In children expectoration reveals nothing, and generally they swallow it, but when it can be obtained, it is white like ordinary sputa. The fever is the most troubling symptom in infantile pneumonia on account of its embarrassing oscillations. However, they are not absolutely the rule, for as in the adult, the temperature rises suddenly to 103 deg. or 104 deg. and maintains that level with slight oscillations between morning and evening, for five or six days. The defervescence takes place towards the seventh day, but the high temperature continues sometimes longer with more or less marked remissions.

When the fever lasts several days in this manner the chest should be frequently examined, as frequently a post-pneumonic empyema will be observed. In any case, the fever is often the principal symptom by which infantile pneumonia is revealed with its usual cortege: saburral condition of the digestive tract, prostration; if the seat of the affection is very limited not exceeding the size of an orange; if it remains central without extending towards the surface of the lung. The physical signs can be so attenuated and so uncertain that the diagnosis remains obscure for five or six days; it becomes affirmative only at the moment of defervescence, when the temperature falls suddenly from 104 to 98 deg.

In presence of a febrile condition with digestive and nervous troubles, and in the absence of physical signs of the respiratory organs, dyspnoea, etc., one is tempted to diagnose typhoid fever; if at the same

time as the fever there exist vomiting and a certain delirium meningitis presents itself to the mind. It is under these circumstances that the difficulties of diagnosis reach their highest point, especially if the physical examination of the thorax is incomplete by reason of the agitation and cries of the little patients, and their general indocility. Every precaution should be taken to ensure a moment of calm on the part of the child, for many grave errors may be avoided by a patient examination.

Percussion signs can be observed two or three days before those afforded by auscultation and can be found beneath the clavicle when the apex of the lung is the seat of pneumonia, a common form in children. The dulness is frequently well marked. On the other hand, thoracic vibrations are frequently absent but bronchophony crepitant rales are always present and easy to detect.

Berlin, January 7th, 1906.

At the Society for Psychiatry and Nervous Diseases. Hr. Borchard spoke on
OPERATIONS FOR TUMOURS ON THE POSTERIOR FOSSA,
MORE PARTICULARLY OF TUMOURS OF THE
CEREBELLUM.

He describes the modern technique for opening up the cerebellum. For opening out a hemisphere a flap of the soft parts was formed with a lower base, which extended upwards 4 to 5 c.m. over the occipital protuberance. The bleeding from the bone incision was arrested by plugs of ivory and bits of wood, and then posterior hemi-craniotomy was performed.

If both hemispheres had to be exposed a larger flap over the whole occipital region was formed and the bone exposed; one after the other the bone of both sides was removed, the bridge between them was then sawn through with Gigli's wire saw. Then followed opening of the dura mater in flaps, and incision of the exposed hemispheres. No, or at the most only partial, suture of the dura mater was required. The cases calling for such operation were: (1) infectious tumours (tubercle conglomerate and gummata); (2) solid tumours, dermoids, cholesteatomata, gliomata, sarcomata, etc.; (3) cysts. The tubercle conglomerates have yielded the worst prognosis up to the present. In spite of this, however, early operation was called for, but serious tuberculous trouble elsewhere was a contra-indication. Gummata afforded a better prognosis. If a six weeks' course of anti-syphilitic treatment was without result an operation should be performed; at any rate, before atrophy of the optic nerve set in. In cases of glioma and gliosarcoma he calculated on 9 per cent. of recoveries. Dermoids and cholesteatomata had not yet been operated on.

Cysts afforded the best prognosis: of 14 cases, 13 had recovered.

Hr. Seiffer showed a patient who had been operated on by Hr. Krause. She walked without any noticeable staggering. She had a tumour of the lateral tract of the cerebellum and exhibited papillary stasis, nystagmus, trigeminal paresis, loss of corneal reflex. Limbourg's sign, cerebellar gait, headache, vomiting, and giddiness—all the general symptoms were improved, the neuralgic pains, the vomiting, staggering, and usual paresis to the right, the disturbance of sensation and papillary stasis. There still remained the nystagmus, loss of corneal reflex, diminution of sensation and deafness.

Hr. Krause observed that he could not take off the bandage. The healing of the wound was normal, but from disturbance of the circulation, the cicatrix projected and fluctuated. On puncture 50 grm. of cerebro-spinal fluid escaped. If the bandage were taken off, there would be danger of infective meningitis. The auditory nerve did not regenerate. The tumour, which was the size of a finger-tip, shelled out easily, and without any hæmorrhage.

At the Laryngologische Gesellschaft, Hr. G. Lennhoff showed a case of

TUBERCULOUS ULCER OF THE GUMS.

The patient was a woman, æt. 35, whose father had

died of pulmonary phthisis. She had had exudative pleurisy eight years ago, and had lost 35 pounds in weight during the last five years. The lungs were practically sound, as shown by percussion and auscultation, but on the alveolar process of the upper jaw was a flattened ulcer, with a greyish white base, pale secretion and excavated border. Small nodules were recognisable in the margin. There was also a flat ulcer, also with nodules, on the right upper gums. The disease had begun two years ago, with a slight feeling of soreness and bleeding on the slightest touch. There was no question of syphilis. The absence of any tendency to cicatrization was against any theory of lupus. No microscopic examination had been made yet.

Hr. Edmund Meyer showed a preparation from a case of

CICATRICAL STENOSIS OF THE PHARYNX AND LARYNX.

The patient, a man, *æt.* 70, had died from pulmonary embolism. For the last 35 years he had worn a tracheotomy canula. On the preparation three cicatricial stenoses one above the other were visible, between the base of the tongue and the posterior wall of the pharynx, between the epiglottis and the posterior wall of the pharynx, and lastly complete stenosis of the larynx.

The *Deutsche Med. Zeitung*, Jan. 1, 1906, reports a case of

BASEDOW'S DISEASE

treated with milk and blood from a goat whose thyroid had been removed. The patient, a married woman, *æt.* 41, commenced her illness after her first confinement. The usual symptoms were present, exophthalmus, palpitation, sweating. In the course of twelve years she was delivered four times and the condition got worse and worse. No treatment availed except that the struma was reduced in size after being injected with Tr. Iodi.

The first attempt was made with blood from a thyroidectomized sheep and was not very successful—but the pulse fell to 88 in the mornings and about 100 in the evenings.

Then the milk from a thyroidectomized goat was begun, after which improvement was steady, the strength increased, the nervous symptom disappeared until the patient could do her housework, a thing she had not done for sixteen years. The eyes receded, the sweatings ceased, and the weight increased by several pounds. When the goat's milk was no longer available, the condition got worse again. Then two goats were procured, and the patient again improved, and when their milk failed their blood was given to the extent of 20 gm. a day. With this the patient's improvement continued, but if she went several days without the milk or the blood she felt at once that the heart became irritable, and the old symptoms threatened to come on again.

Vienna, Jan. 7th, 1906.

SYMMETRICAL LIPOMA.

At the "Gesellschaft," Paschki showed a patient *æt.* 34, with symmetrical lipomas combined with the neuro-fibromatosis of Recklinghausen. Both of these diseases are happily rare, but when they come together in the same patient they become interesting if not instructive in showing a close affinity in their origin. Paschki affirmed that we had very few records of either in literature, and not one hitherto where both diseases have been met with in combination.

INTESTINAL CALCULUS.

Wimmer showed an intestinal calculus taken from a patient in the Maria Theresa hospital measuring 8 centimetres in length, 6 broad; and 19 centimetres in circumference, weighing 320 grammes. The section showed concentric rings around a nucleus with the episperm of grain as a centre from which it originally commenced. It was chemically composed, carbon, carbonic acid phosphate of lime, with the acid phosphates of ammonia and magnesia. The stone was

found by laparotomy immediately above the ileo-cæcal valve, where a tubercular ulcer had existed primarily, with a subsequent arrest of food or the debris of the food that led to the origin of the calculus. The cæcum and a neighbouring portion of the small intestine was resected, the parts brought together and closed, and after 18 days she was dismissed from hospital perfectly cured.

JEKORIN.

Offer next interested the members with his results of the analysis of Jekorin, which has been issued to the medical public as a palladium of sovereign merit by Drechsel, who extracted the substance from the liver of a horse. Drechsel gave the following properties of Jekorin: an alcoholic extract of the liver when evaporated to dryness can be easily dissolved in ether and again precipitated by adding alcohol to this ether solution. This precipitate is not crystalline, and when dried in vacuo with sulphuric acid assumes the appearance of a porcelain mass which again becomes fluid when exposed to the air. This ethereal solution reduces Fehling's solution, and according to Drechsel is a chemical combination of lecithin and grape sugar.

Meinertz has recently made an analysis of Jekorin, and concludes that it is not a chemical body but rather a mixture of lecithin, dextrose and inorganic salts, but the principal ingredient is lecithin.

Offer performed his analysis with the greatest care to avoid hydrolysis during the operation, and with this object in view made a cold extract at a low temperature in vacuo, and obtained the same result as Meinertz. He next reversed the operation by preparing an ætheral of lecithin into which he added a solution of grape sugar, shook them well together and allowed them to stand for some time till the ætheral solution separated from the water solution. The ætheral solution was again washed with pure water and finally with a concentrated solution of magnesium sulphate. After drying off the æther by evaporation a substance similar to Jekorin was left behind, which acted in the same manner as Drechsel's preparation, which, carefully examined, was found to contain lecithin and sugar, but the sugar is feebly bound up with the lecithin. In his further research Offer found two other bodies with distinct chemical and physiological properties—viz., dispentosamin and biose, which are somewhat analogous to Fränkel's albam, although differing from it in not having a nitrogenous combination in the pentose. In this sense it has no hydrolytic influence, although it may combine with five atoms of hydrocarbonous matter.

Budapest, Jan 7th, 1906.

At the recent meeting of the Interhospital Association, Dr. Kadosa read a paper on

GASTROPTOSIS.

He had several cases which had been kept under observation for more than a year, and his conclusions thereon were formulated in answer to the questions:—(1) To what extent is gastroptosis responsible for symptoms? and (2) of what value is prolonged external mechanical support as a means of treatment? As regards the first, he found that these cases naturally fall into two divisions: first, those in which gastroptosis is a primary condition; and those in which gastroptosis is not the main factor in the morbid state. He found that certain cases are relieved so promptly by external mechanical support alone, without any other treatment beyond regulation of the diet, that the downward displacement of the pylorus must be regarded as the primary, or, at least, the principal factor in the causation of the symptom complex. Cases of this character exhibited a moderate diminution of hydrochloric acid secretion, were free from organic disease, and showed no signs of dilatation or impaired mobility. The symptoms were those of malnutrition, gastric fermentation, attacks of frontal headache, and sensations of dragging and lack of support in the abdomen. Gastroptosis may exist absolutely without symptoms. This is shown by the demonstration of down-

ward displacement of the pylorus in the routine examination of other morbid states. Such patients were not benefited by external support, and recovered completely, although re-examinations showed that the stomach was still displaced. Gastropotosis may form a part of the symptom complex of other morbid states, such as neuroses, gastric motor insufficiency and dilatation, and passive congestion of the stomach from weakness of the cardiac muscle. Here the downward displacement of the pylorus is also relieved by a mechanical support. The value of the mechanical support was not exerted in restoring the organ to its normal position, as shown by repeated examination after the belt had been worn for considerable periods of time. It apparently produced some change in the organ which enabled it successfully to perform its functions, although displacement still existed. These changes were probably compensatory in character.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE ADMINISTRATION OF ANÆSTHETICS BY DENTISTS.

—The Crown Office has issued a circular to the two medical corporations in Scotland which grant dental diplomas, drawing attention to the dangers associated with the administration by dentists of such anæsthetics as ethyl chloride, without its having been previously ascertained that the patient was a suitable subject for anæsthesia. That some such warning is not wholly without justification is evident from the fact that notwithstanding the comparatively short time that ethyl chloride has been in use more than thirty fatalities have occurred. The Lord Advocate does not, it will be noticed, in any way prohibit dentists from using what anæsthetics they please; the Crown Circular is rather to be taken as a warning of the responsibility incurred in the administration of such drugs. In a former memorandum the Crown Office advised that a qualified medical man should be present during the induction of anæsthesia; but this, of course, has the disadvantage so far as poorer patients are concerned that it increases considerably the cost of dental manipulations. It seems to us that what both the public and the authorities have a right to demand is that in dentistry, as in surgery, where more prolonged anæsthesia than can be induced by nitrous oxide is required, the administration of the anæsthetic shall be placed in the hands of a skilled person who shall give his whole attention to it. Many dentists, we doubt not, have from large experience of ethyl chloride and similar anæsthetics acquired ample skill in their administration; but this is not to say that it is right for any man to attempt to divide his attention between the administration of an anæsthetic and the carrying out of a dental operation.

TEACHING OF GYNÆCOLOGY IN EDINBURGH.—Since the election of Sir Halliday Croom to the chair of midwifery the University authorities have been engaged on a scheme for the erection of a separate lectureship on gynæcology. The details of the plan have not been made public, and the negotiations which it has involved between the University and the managers of the Infirmary, who are dictators so far as the allotment of clinical material is concerned, are still proceeding. At present the clinical teaching of gynæcology is combined with that of clinical medicine—an association which is as antiquated as, and less reasonable than, its systematic teaching being part of the duty of the Professor of midwifery. It is to be hoped that some way may be found for making the gynæcological department of the Infirmary independent, so far as teaching is concerned, of its neighbours, and utilising the material in a way which has been impossible in the past.

ROYAL INFIRMARY, EDINBURGH.—The manager's annual review of the year's work has just been made public, and was submitted for the approval of the Court of contributors on January 1st. The total number of

patients treated in the wards during 1905 was 11,016—4,178 medical, 6,052 surgical cases. This shows a slight decrease from the previous year, but at the same time, owing to the more extensive employment of newer methods of treating tuberculous and nervous diseases the average stay in hospital of each patient has increased from 24.5 days to 28.3 days. The average daily number of patients in the Infirmary has been 828, as against 810. The out-patients for the year numbered 34,564. The mortality rate was 7.18 per cent, or, excluding deaths within 48 hours of admission, 5.71 per cent. The entire expenditure per occupied bed was £60 11s. 2½d., a decrease of 16s. 7½d. on the previous year, there having been a reduction of 5s. 7½d. on maintenance and 1s. 5½d. on medical expenditure for each occupied bed. The average number of nurses and probationers was 233. The applications for admission to the nursing staff were 794—a steady rise. The chief improvements and additions during the year have been the new surgical out-patient and electrical departments, which have already been mentioned in this column. Among minor changes the surgical theatre belonging to Professor Chiené's wards has been reconstructed, a disinfecting station has been completed, and a new telephone arrangement has been come to by which the installation in the building will be worked by operators of the National Telephone Company. The financial position at the end of the year was quite satisfactory.

LETTERS TO THE EDITOR.

THE LOGIC OF THOUGHT READING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“A Psychological Student,” in your issue of December 27th, has, I think, rendered public service in calling attention to the erratic speculations with which the eminent scientist, Sir Oliver Lodge, is wont to indulge, and in which his name has become a household word. Quite recently a certain prelate is reported in one of the dailies bewailing materialism, thus:—“We cannot forecast the issues of the future and the forces of materialism and selfishness gather into shapes of tremendous and increasing bulk.” It cannot, I think, be wondered at that so many of the more enlightened portion of the community turn with disgust from psychological speculations which exceed the range of human intellect and which defy scientific demonstration, speculations, moreover, which create confusion of thought, foster superstition, and in many instances culminate in insanity. No better instance of this can I think be afforded than what is known as “spiritualism,” concerning which Sir Oliver Lodge seriously and publicly courts investigation, as though we had not enough spiritualism in Buddhism for one world, and enough for all time, especially when we consider its modern development in “Christian Science,” the founder of which maintains we are all spirit and no matter or body. It is surely readily recognisable that any given individual endowed with a hyper-sensitive and moony type of mind could under certain conditions excite what I may be allowed to call artificially produced hallucinations, so that its possessor might vividly imagine him or herself in communication with some deceased ancestor. Granting this condition attainable, what benefit could the spread of such ideas confer upon mankind, or at what scientific value could they be estimated, or what balance could such form of belief render to an unstable mind?

The progress of science has been contemporaneous with increased sanity, hence we find that witchcraft and other forms of superstition have yielded to coherent thought. It is from considerations like these that we expect scientists of Sir Oliver Lodge's calibre to steer the public mind towards a clear and unclouded sky, not to enshroud the student in fog, nor to cause us to revert to the dark ages. It may, I think, be conceded beyond cavil that the sum total of human happiness, prosperity, and peace for the present or for any future

race ultimately depends on the sanity not of the few, but of the many, the only condition which enables an individual to safeguard himself, and one that is certain to prevent him from neglecting his neighbour.

I am, Sir, yours truly,

CLEMENT H. SERS.

Brighton, Jan. 5th, 1906.

A ROYAL COLLEGE OF NURSING.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I correct what appears to be a misunderstanding of my article in the *Westminster Review*?

My suggestion is not that every nurse should be examined once a quarter, but that the examinations for the Primary, Intermediate, and Final Examinations for the degree of B.N. (Bachelor of Nursing) should be held at sufficiently frequent intervals to prevent that waste of time which takes place when examinations are only held once or twice a year!

Your criticism that nursing cannot "be tested by 'a Royal College of Nursing' apart from the Hospitals" is surely contrary to all experience.

Does not every University test for its degrees in Medicine, Law, Arts, Science, etc., apart from the Colleges, and do not the Royal Colleges of Physicians and Surgeons test the knowledge of candidates for their diplomas apart from the Hospitals in which they have been trained?

The nursing profession is now evolving in the same way that the profession of surgery evolved, and surely it is wise to think out ahead the best lines on which its future should be evolved, so as to avoid those anomalies which characterise inco-ordinated and unguided developments.

I am, sir, yours truly,

JOSIAH OLDFIELD.

5, Harley Street, W. January 1st.

SPECIAL ARTICLE.

THE REPORT OF THE INSPECTORS OF LUNATICS IN IRELAND.

THE long-delayed publication of the fifty-fourth report of the Irish Inspectors of Lunatics may have caused hopeful anticipations of some fresh light on the lunacy problem, but these will rapidly vanish on a perusal of the blue book just issued, which, though its period of gestation has been much prolonged, is not in any respect a remarkable production. We learn that the statistics of the increase—or otherwise—of lunacy in 1904 have not been issued till late in December, 1905, owing to the difficulty of getting the financial accounts of asylums for the year ending March 31st ult., furnished in reasonable time, and it is intended to publish the report for 1905 without the financial statements, and the subsequent reports will contain the statistics of the calendar year and the financial statements for the year ending March 31st of the year referred to, thus following the practice of the English and Scotch Commissioners.

Dealing generally with the number of insane under treatment in registered houses it is shown to have increased from 18,094 on January 1st, 1904, to 18,615 on January 1st, 1905. On the latter date 791 were in private asylums and 3,320 in workhouses. From a table in the report, showing the numbers of lunatics under care for the past 25 years, we find that in 1880 the number in District asylums was 8,667, and in private asylums 622, so that in the interval, while the District asylum population increased by 115 per cent., that of Private Asylums and institutions increased by less than 28 per cent.; this discrepancy is still more remarkable when taken into account with the fact that the increase of admission rate into district asylums and private asylums is practically equal for the 25 years, and neither the recovery rate nor death rate accounts for the enormous difference in number of those remaining, which is most probably accounted for by the transfer-

ence of a large proportion of cases to asylums in England and Scotland. The number of insane in workhouses is only 193 less than in 1880, which shows the spirit of reform and progress has no great influence in the matter, as the workhouse treatment of lunatics is universally condemned.

A table showing the percentage distribution of the insane is not without interest:—

Proportion per cent. of total number under care.			
Year.	In District Asylums.	In Work-houses.	In Private Asylums.
1880	67	27	6
1904	81	14	5

The report on the increase in the number of registered insane will be awaited with some hope that light may be thrown on the enormous increase in the number of lunatics in face of a rapidly dwindling population. This overwhelming increase excites only a languid interest in Ireland, but its significance becomes very striking if a comparison is made between the brief table published by the Irish Inspectors and the much more elaborate one furnished by the English Commissioners in their fifty-ninth report:—

Year.	Country.	Number of Insane.	Ratio of Insane to 100,000 Population.
1879	England	69,885	275.40
1880	Ireland	12,982	250.
1889	England	84,340	296.50
1890	Ireland	16,251	344.
1904	England	117,199	347.10
1904	Ireland	22,996	522.

It should be remembered in considering these figures that general paralysis causes 6.5 per cent. of all admissions in England, whereas the total admissions attributed to it in Ireland last year were only 52 or 1.3 per cent. of total. For the second time an abstract from the report of the Census Commissioners of 1901 is republished in the report, from which it appears that in 1851 the ratio of lunatics to population was 1 in every 1,291, and in 1901 1 in every 225, the distribution by Provinces in the latter year, being in Leinster 1 in 242; Munster 1 in 191; Ulster 1 in 286; and Connaught 1 in 238; the highest ratio being 1 in 127 in Waterford, and the lowest 1 in 404 in Antrim County, and Belfast City. The figures of all lunatics and idiots bear much the same relation as regards provincial distribution.

The inspectors note with satisfaction that the admissions, 3,910 in number, have been 40 less than in the previous year and first admissions 22 less, but before taking comfort from this fact the drain of population by emigration should be remembered, and also the average annual number admitted for the ten years 1891-1900, which was 3,302, or 510 above the average annual number of the previous decade. If first admissions are to be regarded as a measure of the incidence of insanity, the opinion is expressed that the fact that they have decreased during the past two years goes to refute the generally held opinion that insanity is increasing in Ireland; over 25 per cent. of the total admissions were from workhouses.

(To be continued.)

Gresham Lectures.

A COURSE of lectures on the "Nervous System," will be delivered on January 23rd, 24th, 25th, and 26th, 1906, at six o'clock each evening, by Dr. E. Symes Thompson, Gresham Professor of Medicine, at Gresham College, Basinghall Street, E.C. These lectures are free, and are illustrated by diagrams, the syllabus embracing healthy nerves, nerves in disorder, the drug habit, and sanity and insanity.

REVIEWS OF BOOKS.

LONDON ON NODAL FEVER (a).

THE object of this work, as the author states in his introduction, is to prove that the disease commonly known as erythema nodosum is really an acute specific infectious fever, and not, as it is usually regarded, merely a skin disease. In support of his premise, he sets himself to prove by reference to clinical cases that the disease is preceded and attended by pyrexia and malaise; that its course is marked by a prodromal period, by a stage of eruption, and by a period of convalescence; and that it occurs under conditions which strongly suggest infection from one case to another.

The author was first led to believe in the specificity of the disease by the observation of a case in 1879, and since then he has carefully observed many similar cases, the records of which, with added comments, form the major part of the book. Of all his premises the weakest appears to us to be the proof of the infectious nature of the malady, as most of the cited instances of transmission could readily be explained on other grounds. On the other hand, a fairly good case for the existence of prodromal symptoms is made out, and the charts leave no doubt of the occasional existence of fever. We cannot, however, feel that the author has proved his case, for it would not be difficult to show that other skin diseases, such as eczema and pimphigus, are attended by similar phenomena. The existence of fever is, we contend, merely a proof that bacterial toxins are being absorbed, in much the same way as they are absorbed from septic wounds, *i.e.*, from a local skin infection. Of more interest is the observation that the affection is not so closely connected with rheumatism as is generally believed. This is, we believe, substantially true, and is borne out by recent statistics.

While not agreeing with Dr. Lendon's conclusions, we have nothing but praise for his work. Clinical observations like his help to keep alive an interest in ordinary work, and prevent us from becoming stereotyped in error through accepting without criticism the unsubstantiated conclusions that have been handed down to us. The book contains some excellent coloured plates, and is nicely got up. We recommend it to all practitioners who take an interest in skin cases.

ROBERTS' THEORY AND PRACTICE OF MEDICINE (b).

THERE was a time when Roberts' Medicine was the guide, philosopher and friend of a host of students, and we have little doubt that had the editions been kept up-to-date it would have held its own against the younger competitors that of late years have been crowding into the field. After a long interval a tenth edition has just been issued, and after careful reading we have come to the conclusion that this famous work is destined to take a fresh lease of life. It retains all the old qualities that made it popular—freshness, vivacity, and sustained interest—and in addition it has been brought scrupulously abreast of modern knowledge. We cannot but admire the courage of the author in taking on his shoulders the task of writing a system of medicine, complete except for mental and skin diseases, without the aid of any collaborateur, but the fact of his having done so, and done so successfully, shows that it is still possible in these days of specialists and sub-specialists for a large, catholic-minded, and full physician to take the whole of medicine for his province, and to expound

(a) "Nodal Fever (Febris Nodosa)." By Alfred Austin Lendon, M.D.Lond., Lecturer on Obstetrics and Clinical Lecturer on Diseases of Children, University of Adelaide, &c. London: Bailliere, Tindall and Cox, 1905.

(b) "The Theory and Practice of Medicine." By Frederick T. Roberts, M.D., B.Sc., F.R.C.P., Emeritus Professor of Medicine at University College, Consulting Physician to University College Hospital, and to Brompton Hospital for Consumption. Tenth Edition. Two Vols. London: H. K. Lewis. Price 26s. net.

it in its every phase. There is, it is to be feared, a danger that in the not-far-distant future text-books in medicine will become the joint works of many writers, and that the impress of a personal mind governing the whole will be looked for in vain. It is of the utmost importance, especially in the case of students, that medicine should not come to be regarded as an aggregation of facts, but should remain ever bearing the appearance, as at the bottom it has the substance, of a consistent whole. A system of medicine should, in the ideal, be the criticism of a master-mind on the facts brought before it in the course of long experience and study, and should go out to the world as an expression of opinion, self-contained, complete, and interpretive. For these reasons we cordially welcome this ripe product of the life-work of an accomplished physician, and congratulate him on having brought it to a conclusion without co-operation or delegation. But we confess to some disappointment that Dr. Roberts has not given us more of himself and his own views, and less of the undigested opinions and statements of others. We recognise that for students preparing for examination it is necessary to give alternatives to suit different kinds of examiners, but the book loses in critical value in proportion as statements, uncorroborated by the author's opinion, are given for what they are worth. This disappointment is the keener by reason of the ability of Dr. Roberts to speak as one having authority, for when he takes a clear and strong line it is always characterised by a robust common-sense that does credit alike to his judgment and perspicacity. These qualities enable the author to maintain throughout a high sense of value, and it will be remarked with especial pleasure that there are no fads introduced, and no fancies given play to; the work sails throughout on an even keel. Bias, if bias there be, is the pardonable one in favour of University College experience and the work of University College men; but there is a distinct usefulness in tinting a text-book with the colours of a particular school, especially if these be laid on, as in this case they are, with due artistic feeling. Those who are acquainted with the former editions of this work will recognise with pleasure the familiar terse, epigrammatic style, which Dr. Roberts wields with such ease. Here and there we come across rugged sentences, but the general effect is the effect of Cæsar, vivid from the absence of adornment or qualification; essentially virile. The book shows evidence of careful revision and its value is decidedly enhanced by the possession of a capital index. It is well bound, clearly printed, and nicely got up. The pleasure we have derived from reading it will, we are confident, be shared by several generations of students, for it is a sound, accurate, balanced, and brilliant résumé of modern medicine.

GRAY'S ANATOMY.*

ONCE more a new edition of the ever-profitable "Gray" comes before us for review, although it is a book whose popularity and good qualities need no bush. The present edition has been carefully revised and in part re-written. A considerable number of additional drawings have been added, especially in connection with the chapters on Embryology, the Nervous System, and the Organs of Sense. All half-tone illustrations have been re-drawn and replaced by woodcuts and line drawings, thus bringing them more fully into keeping with Carter's original illustrations. Gray's "Anatomy" will soon celebrate its jubilee, as for forty-seven years it has lightened the labour of generations of medical students. Its motto truly may be "Canus, sed semper viridis," for though decades roll over its head it is always in the forefront of anatomical knowledge.

* "Anatomy, Descriptive and Surgical." By Henry Gray, F.R.S., F.R.C.S. With drawings by H. V. Carter, M.D. Sixteenth Edition. Edited by T. Pickering Pick, F.R.C.S., Consulting Surgeon to St. George's Hospital, and the Victoria Hospital for Children, and by Robert Howden, M.A., M.B., C.M., Professor of Anatomy in the University of Durham. London: Longmans, Green and Co. 1905. Pp. 43 and 1,248.

MARSHALL ON MATERIA MEDICA. (a)

DR. MARSHALL, of University College, Dundee, and Professor of Materia Medica in the University of St. Andrews, is a well-known authority on pharmacology, whose studies of the organic nitrates, the action of digitalis and other members of the nitrite group, are familiar to our readers. He is one of the small number of experimental workers on the physiological effects of remedial agents which, unfortunately for the progress of medicine, is gradually growing smaller in Great Britain. That he should have written a book on materia medica is a subject for congratulation. Needless to say, a work from the hands of so experienced an observer is marked by a degree of accuracy and attention to minute details which is rare in such compilations. It is not only a much-needed guide to the British Pharmacopœia, but an introduction to the study of pharmacology and therapeutics. Although not dealing primarily with experimental investigation, the results obtained by it when capable of practical application are mentioned, and in some cases experiments on animals are described.

Many of the definitions given in this work, reflecting as they do the outcome of recent researches in chemical pharmacology, will come as a surprise to the average English medical student nurtured in the school of Garrod and his successors. For example, whilst Dr. Marshall frankly admitted that no satisfactory definition of an alkaloid has yet been given, it is provisionally stated that alkaloids are "nitrogenous vegetable products which have the nitrogen combined in the form of a closed ring." Atropine is defined as "an alkaloid $C_{17}H_{23}NO_5$, the solution of which does not rotate a ray of polarised light, obtained from belladonna leaves or root." It is doubtful if atropine exists as such in the plant, for hyoscyamine is readily converted by the action of heat or alkalis into atropine. Dr. Marshall deals with the somewhat complicated subject in a masterly manner, and his article on the pyrrolidine group is one of the best in the book. In almost every instance the inter-relationship existing between the natural alkaloids of various groups is illustrated by diagrams, a mode of instruction which greatly facilitates the work of the student. It must be understood that the volume, although nominally a text-book, contains a considerable amount of original matter, and that although described in the Preface as being elementary in character, it comprises a description in brief of much advanced teaching. It is a credit not only to the author, but to the Scotch Universities, of which he is so distinguished a member. Incidentally it may be remarked that the book is admirably illustrated.

SHAW-MACKENZIE ON THE NATURE AND TREATMENT OF CANCER. (b)

In the preface to this new edition the author states that he has amplified, extended, and revised his former work published under the title of "Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer." We think he has done wisely in placing before the profession, in so convenient and handy a form, the results of his latest investigations and conclusions in respect to the nature and treatment of cancer. In the ninety-eight pages of which the small volume consists is contained the most possible explanation of the cause of cancer, based upon incontrovertible scientific data, of which we have knowledge at the present time. Cancer, after all, may be but a simple disease—simple in the sense of being merely dependent upon some nutritional defect or disturbance. Now that the parasitic theory of its origin has been

generally discounted, the chemo-biological theory, to say the least, is replete with interest and possibilities. A careful perusal of this work shows that the author is able to attribute the nutritional defect present in malignant disease to the loss of functional power of the pancreas. That is to say, that the unrestrained cell-growth characteristic of cancer is probably dependent upon the absence in the body of the proteolytic pancreatic ferment, known as trypsin.

This, in a few words, forms the main line of investigation which the author follows and portrays in the work before us. The details by which he arrives at his conclusions and the scientific data, largely based upon the valuable original work on embryology published by Dr. J. Beard, of Edinburgh, demand thoughtful and careful perusal, for the purposes of which we must refer the reader to the book itself. Furthermore, it must be conceded that the author's observations upon the possible connection between cancer and diabetes are most suggestive and interesting. Here again he adduces scientific data tending to confirm his conclusions. It may be, therefore, that we are upon the eve of one of the most epoch-making discoveries in pathological science. The volume before us is, indeed, very suggestive of the possibilities of this. Let us reflect for a moment how pathology as a science has been evolved in the past, and how within comparatively recent times the study of bacteriology threw a flood of light upon the etiology and progress of disease. The startling fact in this new work on cancer is that the disease has been traced to an embryological origin, and so closely do all the latest experimental and clinical, accord and dovetail with each other in this connection, that it is almost impossible to avoid the conviction that the author has succeeded in placing before us a perfect sequence of the nature and treatment of cancer, which may hereafter prove to be the stepping-stone to the arrest and cure of this terrible and fearful malady. So greatly have we been impressed by the perusal of this work that we can only recommend every practitioner to study it carefully, and with an open mind—inasmuch as we regard it as one of the most important contributions to the literature of the subject with which it deals which, so far, has been issued from the press.

ENCYCLOPEDIA OF MEDICINE. (a)

This volume of Nothnagel's series is divided into two portions, the former on Diseases of the Kidneys occupies 450 out of a total of 800 pages, and is written by Senator, while the latter part on Diseases of the Spleen and Hæmorrhagic Diseases is from the pen of Professor Litten. Both authors have long since made their mark both as systematic writers and as investigators on the subject of which they treat, and consequently what they say, with but little exception, may be taken as expressing authoritatively current German ideas, which, however, do not in all cases coincide with English opinions. As might have been expected, most of the references given are to German authors and papers, but justice is also done, more especially in the historical accounts of diseases, to the work of Anglo-Saxon clinicians and pathologists, any defects in this respect being partly compensated for by editorial addenda.

The treatise on kidney diseases commences in the traditional manner, with an account of various morbid conditions of the urine, albuminuria and albumosuria being first dealt with. In describing the tests for albumin one is glad to note that attention is drawn to the fallacy inherent to the nitric acid test owing to the occasional precipitation of nitrates. This is a most important fallacy, owing to its very infrequency, and

(a) "A Text-book of Materia Medica", By C. R. Marshall, M.D. Professor of Materia Medica and Therapeutics in the University of St. Andrews. London: J. and A. Churchill. 1905.

(b) "The Nature and Treatment of Cancer: Some Methods of Hypodermic Medication in the Treatment of Inoperable Cancer." By John A. Shaw-Mackenzie, M.D. Lond. Second Edition, Revised and Enlarged. London: Baillière, Tindall and Cox. 1905. Price 2s. 6d.

(a) "Nothnagel's Encyclopædia of Practical Medicine, Diseases of the Kidneys, and of the Spleen: Hæmorrhagic Diseases." By Dr. H. Senator, Professor of Medicine, University of Berlin, and Dr. M. Litten, Professor of Medicine, University of Berlin. Edited with additions by Dr. James B. Herrick, Chicago. Authorised translation under the editorial supervision of Dr. Alfred Stengel, Pennsylvania Philadelphia: W. B. Saunders and Co. 1905.

yet it is often entirely passed over even in books on urine analysis. One cannot, however, help feeling surprised that the heat test with the addition of acetic acid is slightly spoken of, for our own opinion and that we believe of many competent clinicians is that it is both more reliable and also more easy to carry out than any other of the innumerable albumin tests. Senator's opinions on cyclic albuminuria coincide with those expressed by authors who have specially studied the subject. He does not however, attempt to lay down any rules whereby one may distinguish the organic from the purely functional affection, nor does he make any overt reference to the "vascular asthenia" hypothesis of Gull. The author's criticism of the various theories of urinary intoxication is necessarily destructive, but when he attempts himself to formulate a theory his ideas are so obscure either by faulty expression or mistranslation that it is impossible to understand his meaning. We refer more especially to the third and subsequent paragraphs on page 108. A very good account of the steps in the development of our knowledge of the non-suppurative inflammation of the kidney from the time of Bright to the present day is given, and an elaborate attempt is made at a complete classification of the various morbid states included under that name. We are, however, in entire agreement with the editor's remark that neither clinically nor from the standpoint of morbid anatomy can the cases be grouped in a manner entirely satisfactory, and that it is useless to worry over the proper use of the term Bright's disease. On the whole, however, the subject is treated with clearness and completeness, but its complexity will prevent any but the most advanced students of pathology and medicine from appreciating it at its full value.

Turning to the second part of the work, one is surprised to notice some serious omissions. No reference at all is made to Von Jacksh's splenic anemia of infants, and the condition of the spleen in rickets is almost as completely passed over. One cannot help also expressing regret at the American slang that here and there disfigures the pages. To quote an example, we find on page 603 some advice given to the surgeon who contemplates "going in" to the abdomen, and numerous other instances could be given. Expressions of this sort certainly have the merit of lacking artificiality, and may be expressive and to the point in a class room, but in a work of this sort a little more literary style should be aimed at. The above remarks of course, apply to the translator, and not to the author, whose work is admirably done.

The volume is bound in the manner that we are all now familiar with and has a good index. Its place will be rather on the shelves of the scientific worker, than in the hands of the general practitioner. It is, in fact, what it is called, a true encyclopædia, and forms a milestone to mark the high-water level of our knowledge at the commencement of the twentieth century.

LITERARY NOTES.

DR. ARTHUR SHADWELL, the author of "Drink Temperance, and Legislation," is about to issue through Messrs. Longmans, a two volume work under the title, "Industrial Efficiency."

DR. JOHN D. COMRIE has prepared a new "Medical Dictionary," which is to be issued by Messrs. A. and C. Black, uniform with "Who's Who."

THE "Medical Annual" for 1906, we are glad to see, in spite of the disastrous fire at Messrs. John Wright and Co.'s works at Bristol, will not suffer delay in its appearance.

"IN determining the relative values of disinfectants there can be no acceptable standardisation which, having regard to one quality only, ignores all others which are equally important." This is the basis on

which a small and instructive pamphlet now before us is founded, entitled "A Straight Talk about Disinfectants, and their Relative Values." The standardisation of disinfectants can hardly be placed in the same category as that of drugs, because the disinfectant that is considered best in surgery would scarcely be suitable for drains, nor should we be inclined to use the same for purifying the air of a sick chamber as for the destruction of decomposed refuse. There is room, we think, for all disinfectants properly so-called, and we think the writer has made out his case.

THE current number of the *Cyclists' Touring Club Gazette* contains an illustration of the beautifully simple and artistically useful roadside granite seat erected on the spot where death came to the late and much lamented Dr. Gilbert Smith, long to be remembered by staff and students of the London Hospital and a wide circle of friends.

MR. SWINFORD EDWARD'S monograph on "The Diagnosis and Treatment of Carcinoma of the Rectum" (Bailliere, Tindall and Cox) throws light on a comparatively common disease, one in which early diagnosis is all-important. The chapters on diagnosis will interest the practitioner, and those on the various operative procedure the surgeon—and possibly also the patient. While the perineal operation gives by far the smallest mortality, the choice of procedure must necessarily in great measure depend upon the site and extent of the growth. The results of early operative treatment are certainly very encouraging, especially when one reflect on the dreadful fate reserved to sufferers from rectal cancer when colotomy was held to constitute the only admissible intervention.

DR. G. A. H. BARTON has written a useful brochure, entitled "A Guide to the Administration of Ethyl Chloride," which gives the result of his own experience of this anaesthetic during 1,500 administrations. On the whole, Dr. Barton is highly pleased with the drug, but he candidly points out its drawbacks and limitations. He describes and figures an apparatus of his own invention for giving ethyl-chloride for operations on the nose and throat which last several minutes, and certainly it seems to have worked very satisfactorily in his hands. Dr. Barton is an advocate of the ethyl-chloride-ether sequence which is becoming so popular now, but we confess to being somewhat taken aback at the combined chloroform and ethyl-chloride method he uses. The pamphlet is well worthy of careful reading.

THOSE who are acquainted with Sir William Collins's writings must always feel regret that his onerous public duties prevent his contributing to medical literature more fully than he has done. Sir William Collins's occasional essays on medical subjects have a charm and distinction of their own; their originality of thought, philosophical breadth, and decisive expression strike cords that are left untouched by many of the present-day wares on the booksellers' stall. We have before us a pamphlet, "The Crystalline Lens in Health and in Cataract," which contains a reprint of the address given by the author at the Oxford University course on Ophthalmology last summer, and we venture to predict for those who read it—be they ophthalmic surgeons or general practitioners—half an hour's enjoyment in the region of pleasing ideas and stimulating thoughts.

"TIME and Tide" is the heading of a peculiarly attractive series of paragraphs which appear weekly in *The London Argus*, written by that versatile poet, novelist, and physician, Dr. G. R. H. Dabbs, whose most recent work is entitled "The Ladder of Pain."

THE first two sections of Dr. Turban's "Beiträge Zur Kenntnis der Lungen-Tuberculose" have been translated by Dr. E. C. Morland, and published under the title of "The Diagnosis of Tuberculosis of the Lung, with Special Reference to the early Stages."

MEDICAL NEWS IN BRIEF.

Liverpool Institute of Commercial Research in the Tropics.

SIR ALFRED JONES has secured the services of Mr. Malett, late Minister of Agriculture in the Congo Free State, to deliver lectures and addresses to the natives along the West Coast of Africa, in conjunction with Viscount Mountmorres and the other expert connected with the expedition who are going out from the Liverpool Institute of Commercial Research in the Tropics. It is considered that Mr. Malett's experience in the Congo, extending for a period of seven years, will prove valuable. He sails from Liverpool to-morrow.

The Cost of Small-pox.

If more than a hundred cases of small-pox occur in any district in a year they are treated as an epidemic. No fewer than nineteen such outbreaks occurred in the year ending March last. The worst case was that of Dewsbury, where 548 cases were reported, and the amount of expenditure in the twelve months came to about £12,397. It began in November, 1902, and ceased in March of last year, and involved an expense of nearly £14,000. Gateshead, Newcastle, Oldham, and Ravensthorpe each had more than three hundred cases of small-pox, and Leicester over two hundred. These outbreaks, of course, are very expensive, and teach the necessity of strict sanitary precautions and of vaccination.—*Western Morning News.*

Durham County Asylum—Dismissal of Two Officers.

An extraordinary occurrence has been reported at Durham County Asylum in the dismissal of two officers. If the details of the affair be authenticated strong action is demanded in the interests of the public no less than of the medical profession. It is stated that the only cause of offence alleged against the officers in question was that they had complained of the negligence of the stores department of the Asylum in not supplying articles of clothing requisitioned for the use of the patients. This neglect extended over a period of several months, and its existence appears not to have been disputed. The Committee of Visitors, nevertheless, called upon the medical officer and the matron to resign. It is to be hoped that the Local Government Board will order an immediate investigation into the matter. If the medical officer belongs to the Medical Defence Union or one of the kindred protection societies he will be able to enlist their powerful sympathy and help in frustrating what appears to be a gross injustice.

A Medical Man Censured for Neglect at Barnsley.

At an inquest held at Barnsley last week upon a colliery shunter, aged 27, who died from being crushed between a light engine and a wagon, it was stated that Dr. Ritchie, of Hoyland, failed to attend when called for immediately after the accident. A second messenger was despatched, and the doctor advised the removal of the wounded man to the hospital. It was stated that the man had by that time lost much blood, which prompt medical attendance would have avoided. Dr. Ritchie explained that he was suffering from an acute attack of lumbago when called. He requested that Dr. Wiggins, his partner, should be summoned, but when he found that Dr. Wiggins had another appointment he (Dr. Ritchie) started off. Meeting the second messenger on the way, he learnt that the injured man had been properly bandaged, and ordered his removal to the hospital. The jury, in returning a verdict of "Accidental Death," expressed their opinion "that Dr. Ritchie ought to be censured for his gross neglect in not attending to the deceased before his removal to Barnsley." The Coroner, addressing Dr. Ritchie, said it was his painful duty to censure him for the neglect he had shown, especially in view of the fact that he was paid to attend to these cases. Considering the man would be two hours before receiving medical attention, he (the coroner) confessed that he, to a great extent, agreed with the jury.

The Working of the Aliens Act.

THE Aliens Act is now in full swing. During the past week a number of aliens were excluded, including a sick Chinaman from a liner. On Thursday the sanitary authorities declined, on medical grounds, to allow three out of the eleven foreigners carried by the "Batavier IV.," from Rotterdam, to land. All the immigrants were Russians with the exception of a Portuguese sailor—one of the three detained—the party including two women and three children. The Portuguese sailor, who had been engaged on British ships for some time, in the course of his travels acquired a highly contagious disease, and with the object of curing it, he decided to book his passage to London, and get the best attention possible in hospital. The doctors at Gravesend, however, in the exercise of their duty, expressed a different opinion, and unless an appeal is speedily lodged, the sailor will be promptly sent back to Rotterdam. The other cases rejected were those of a woman suffering from dropsy and a man afflicted with cataract. So, whereas the fortunate eight were allowed to land at Gravesend, the remainder were detained on the "Batavier IV." in St. Katherine's Dock. A Syrian alien, suffering from cancer, who was detained at Dover on Wednesday, was eventually allowed to land, as he was proceeding to America. The Act, at this rate, will be speedily ridiculed and unworkable. Apart from medical grounds, the following case shows the inherent feebleness of the principles of this retrograde legislation. Twelve onion-sellers may be permitted to invade Devon, but not an army of seventeen. On the arrival at Plymouth on Thursday of seventeen Frenchmen from Roseoff, for onion-selling in South Devon, the Customs authorities prevented them from landing. Telegraphic instructions, however, were received from the Home Secretary to permit all of them to land after being duly warned that, in future, the Act would be strictly interpreted, and the number limited to twelve aliens, as the Act provides.

Important Pharmacy Prosecution in Liverpool.

At the Liverpool County Court on the 3rd inst., Judge Shand had before him a prosecution on behalf of the Pharmaceutical Society of Great Britain against John Thompson, unqualified assistant to Stephen Stephenson, chemist and druggist, for selling poison contrary to section 15 of the Pharmacy Act, 1868. Evidence was given by an official of the society that on October 23rd last he purchased from the defendant at Mr. Stephenson's shop, a penny package of white precipitate powder and a bottle of Mrs. Winslow's Soothing Syrup, both of which contained poison. Mr. Thomas Tickle, analytical chemist, deposed that the package of white precipitate powder contained enough poison to kill two or three people at least. It was a powder in common use by the public as a vermin killer applied to the human skin. The Judge.—Do you mean to say that anyone who goes into a chemist's shop and asks for it can get it, merely on stating that it is to kill vermin? The Witness.—I understand that the person who makes the sale is required to be a registered chemist or druggist. The Judge.—I know that, but can anyone get it on that representation? Mr. Nield.—Yes; they get it as a matter of course. The Judge.—Is that all the safeguard the public have, that if it is supplied by a registered chemist and druggist anyone can get it, and for a penny enough to poison at least two or three people? Mr. Nield.—That is so. There are two schedules of poison—one containing the more dangerous poisons, which can only be sold to a person known to the seller. The Judge.—Is white precipitate one of them? Mr. Nield.—No, it is not. The Judge.—Good gracious! What about the others; how many people would the more dangerous poisons kill? Mr. Nield.—I don't know, but they are mostly ten times as strong, or more.—The Judge.—Then the same quantity would

kill thirty people, but a poison that will only kill two or three does not matter apparently. (Laughter.) Mr. Niell.—There you must trust to the seller, and that shows the necessity for their being qualified. The Judge.—The real offender goes scot-free. Mr. Niell.—Yes; the real offender employs these persons because he gets them cheaper than qualified men. The Judge.—Is Thompson a boy or a man? Mr. Niell.—He is about 22 years of age. The Judge.—Of course, under section 15 he is liable, but I don't believe for a moment that he is the principal offender. Apparently, the Act is silent as to the more serious offender, but if there is any procedure possible against the principal offender the society should get at him, because this defendant is really only his tool. The defendant was then fined the full penalty of £5 and costs, to be paid forthwith.

Antwerp International Exhibition.

We are asked to announce that Medicine and Public Hygiene will form an important Section at this exhibition, which will be opened in April, and continued during May, 1906. Pharmacy, dietetics, wines, &c., will also be included, the enterprise being under official patronage.

Westminster Hospital Medical School.

A course of lectures on "Applied Physiology," will be delivered at the School, on Thursdays, commencing Jan. 18th, at 5 o'clock, 1906, by Bertram Abrahams, M.B., B.Sc., F.R.C.P., Assistant Physician, Westminster Hospital, and Examiner in Physiology to the Conjoint Board. They will be open, without fee, to graduates and students of the University of London, and to qualified practitioners.

Society for the Study of Disease in Children.

The Wightman Lecture of this Society will be delivered on Friday, May 18th, by M. le Docteur August Broca, *Professeur Agrégé* Surgeon to the Hôpital des Enfants-Malades and President of the Société de Pédiatrie of Paris upon "The Diagnosis and Treatment of Appendicitis in Children."

Royal Academy of Medicine in Ireland.

The Council of the Pathological Section of the Academy have decided to hold on Friday, February 16th, a general discussion on every aspect of "Abdominal and Pelvic Tuberculosis." Sir Thornley Stoker, President of the Academy, has kindly promised to preside. Papers and speeches will be limited to ten minutes each. The following Fellows of the Academy have kindly consented to open the discussion: Dr. James Little, Sir Arthur Chance, Sir William Smyly, Professor McWeeney. The Hon. Secretary of the Section (Professor White, Royal College of Surgeons) will be glad to receive the names of Fellows or Members anxious to join in the discussion.

London Post-Graduate Lectures.

DR. E. F. TREVELYAN, of the University of Leeds, has kindly consented to open the spring course of Post Graduate Lectures of the Mount Vernon Hospital held in the Central Out-Patients' Department, 7, Fitzroy Square, with an introductory address on Thursday, January 18th, at 5 p.m., his subject being "Modern Methods of Diagnosis and Treatment of Pulmonary Tuberculosis." Medical practitioners and senior students are invited to attend.

The Election of Direct Representative for Ireland.

SIR WILLIAM THOMSON has issued a second address to the medical profession in Ireland, at the end of which he publishes a list of supporters. The address refers at some length to his work on the Council, especially with regard to the Royal Army Medical Corps. It also refers to the circumstances under which he brought the grievances of the Irish Poor Law Medical Officers to the notice of the Council. We understand that the eleventh hour has produced a further candidate, and that in addition to Sir William Thomson and Dr. Kidd, Dr. Laffan of Cashel, pro-

poses to again stand. If the members of the medical profession throughout the provinces are really desirous of returning one of their own number instead of a Dublin representative, it seems unwise for more than one candidate to come forward.

Royal College of Surgeons, Ireland, School of Surgery.

We have received from the Registrar of the College a very complete syllabus of the Schools of Surgery connected with the College. These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College Buildings, and are specially subject to the supervision and control of the Council. The buildings have been re-constructed, the capacity of the Dissecting Room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with the most approved appliances, in order that students may have the advantage of the most modern methods of instruction. A refreshment room is now open, where students can have luncheon. There are special rooms set apart for lady students. All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College. In addition to full information regarding the various courses, a number of the questions set at recent preliminary examinations of the Conjoint Colleges are given as specimens of what the intending candidate may have to answer. To all students desiring information regarding their medical studies the pamphlet will be of much value.

Pencils as a Cause of Diphtheria

THE correspondent of the *Daily Telegraph* reports from New York that in Detroit school-pencils have caused an epidemic of diphtheria. The School Board buys pencils for the pupils, and these are gathered up each night and distributed in the morning. One child contracted diphtheria, and in a few days the disease was communicated to fifty pupils. The State Board of Health has now ordered the pencils to be destroyed and the system abolished. In the United Kingdom, the danger of slates as an agency for infection has long been recognised, but pencils seem to have hitherto escaped attention.

Society for Study of Inebriety.

THE last meeting of the above Society was held on Tuesday, January 9th, 1906, in the Rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W, when Dr. THEO. H. HYSLOP (Resident Physician and Medical Superintendent Bethlem Royal Hospital) opened a discussion on "The Vitality of a Nation," an abstract of which will be found in another column under the heading of "Original Papers."

OBITUARY.

MR. M. H. GREENER, M.B., C.M. GLAS.

WE regret to announce the death of Dr. Michael Hindmarsh Greener, on December 26th, 1905, at Cardiff. He succumbed to an acute attack of pneumonia after a short illness. Born in Alnwick in 1858, he graduated as M.B. and C.M. at the University of Glasgow in 1884 and shortly afterwards began to practise in Cardiff, where he held several honorary appointments. He leaves a widow, a son, and a daughter to mourn their loss.

DR. JOHN CAMPBELL, F.R.C.S. Eng., is to be nominated for the seat on the Royal University Senate, rendered vacant by the resignation of his Honour Judge Shaw. Dr. Campbell is President of the Graduates' Association, and takes a deep interest in educational matters.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for the MEDICAL PRESS AND CIRCULAR.

SURGICAL SUMMARY.

Remarks on Shock.—Malcolm (*Brit. Med. Journ.*, 1905, December 9th) points out that in shock, sleep, extreme lowering of the surrounding temperature associated with bodily exhaustion, death from old age, and death from certain complicated febrile conditions have many features in common. The functions of the central nervous system are partially in abeyance, owing to exhaustion, so that the patient loses consciousness and the power of sensation and motion, while the temperature tends to fall. Cardiac, respiratory, and nutritive changes necessary to life are, however, carried on with a lowered degree of activity. In shock in the case of an injury the exhaustion of energy seems to be due to an over-stimulation of the sensory nerves whether the stimulus is applied gradually during an operation, or suddenly as in the case of severe accident. Some years ago it was usually taught that the cause of shock was a paralytic dilatation of the vessels in the area supplied by the splanchnic nerves, followed by anæmia of the brain. In operating on the abdomen, however, there is no evidence of this condition, although a severe state of shock may exist. Malcolm considers that in shock, and in all cases where there is a loss of consciousness, without any discoverable brain lesion, unconsciousness is due to nerve exhaustion and brain anæmia, dependent, except in sleep, to an intense contraction of the arteries. When an artery contracts the change begins in the arterioles and gradually extends to the larger vessels, and relaxation takes place in the reverse order. Clinical symptoms agree with this statement. The alterations in the circulation can be more easily followed in the slowly progressing changes in the vessels, accompanying the febrile process. Thus in the commencement of a fever when the capillaries contract the pulse is full and bounding, then as the radial artery contracts the pulse becomes small, hard, later thready, and finally imperceptible. Again, in shock, the blanching of the skin, the complete or partial anuria, the beneficial effects following the administration of vaso-dilators, such as nitro-glycerine and alcohol, and the application of heat, are best explained by contraction not dilatation of the blood-vessels. In conclusion the author maintains that his views as regards the causation of brain anæmia in shock are founded on the well-known physiological fact, that stimulation of a sensory nerve causes vaso-constriction, whereas the view that a general paralysis of the arteries is caused by an injury has no such basis. S.

Quinine Treatment of Corneal Ulcers.—Lawson ("Transactions" of the Ophthalmological Society of the United Kingdom, Vol. XXV.) after several years experience of this treatment reports strongly in its favour. Although not wishing to recommend it as a panacea for all forms of ulcers he attaches the greatest value to it. Tweedy first introduced the treatment for membranous conjunctivitis and neuropathic ulceration of the cornea with good results. The ulcers Lawson found to be the most suitable for quinine treatment are: (1) large ulcers involving the true cornea and not very infective; (2) marginal, scalloped and ring ulcers; (3) all infiltrating and infective ulcerations which are not undermining the edges and which are not accompanied by rapid hypopyon formation; (4) neuropathic ulcers. The treatment has proved uncertain in acutely infective ulcers, the edges of which are undermined and in which rapidly forming hypopyon occurs, as also in those forms of ulcers known by the name of Mooren and dendritic. The author does not advise this treatment in small superficial ulcers which usually heal readily under simple and less irritating lotions and a bandage. As to the form of the quinine solution he recommends

4 grains of the sulphate of quinine in 1 ounce of water, the least possible amount of dilute sulphuric acid being used to dissolve the salt. The eye is thoroughly douched with this solution for five minutes by means of an ordinary eye bath. This is repeated four or five times a day. Atropin is instilled twice a day and a bandage applied. Many ulcers treated ineffectively by other popular lotions have healed rapidly, and with less subsequent opacity under the quinine lotion. M.

The Significance of Eye Symptoms in Sclerosis of the Brain.—Prof. Uthhoff of Breslau ("Ophthalmoscope," Vol. III. No. 9) gives a summary of his own experience of eye symptoms in disseminated sclerosis. In nearly half of his cases the ophthalmoscopic appearances were pathological and consisted of simple atrophic alteration in the colour of the papilla. Atrophic discolouration of the whole papilla was comparatively rare, forming only 3 to 4 per cent. of the total. Cases of incomplete atrophic pallor of the whole papilla, so that the inner parts still retained some slight pinkish tint, and cases in which there was partial limited atrophic pallor of the temporal part of the papilla formed 20 per cent. of all cases. Uthhoff has not observed typical congested papillæ, but he considers that the atrophic pallor of the disc is more often of an inflammatory neuritic nature than appears at first glance. In about another 5 per cent. of cases disturbances of vision occurred without any ophthalmological changes being visible. The clinical manifestations of visual trouble were very various, but for the most part the amblyopia of disseminated sclerosis resembled the visual disturbances one observes in retrobulbar neuritis. The defects in the visual fields were also very various—viz., (1) Central scotoma with full periphery, the scotoma being generally binocular and relative; (2) central scotoma with peripheral contraction in rare cases; (3) fairly frequently were found irregular contractions of the periphery; (4) in isolated cases regular concentric functional contractions of the fields can be found in multiple sclerosis, as well as when the disease is complicated by hysteria; (5) ring scotoma were rare as were also another form; (6) in which there was at the outset a certain anomaly—e.g., central scotoma—was present and it cleared up to be followed by another anomaly—e.g., concentric contraction. Uthhoff has comparatively often found sclerotic changes in the chiasma and optic tracts, yet he has very seldom found anomalies of a hemianopic form. In about half the cases the visual troubles set in rapidly and were followed by improvement in about half of these, a fact not suggesting simple degeneration of the optic nerve fibres. In the other half of the cases visual failure came on slowly. One or both eyes were affected and permanent bilateral blindness was a rarity. Recurrences were common. Transitory, complete blindness in one eye was fairly common. Defects in the colour vision are relatively insignificant and are liable to be overlooked. Paralysis of eye muscles occurred in 20 per cent. of Uthhoff's cases. The percentage would have been considerably increased had pareses of slighter shades been included. The paralyses are generally incomplete and transitory. A complete lasting paralysis was seldom seen. The sixth nerve was the one most commonly affected. In only two cases out of 150 did Uthhoff find complete paralysis of all extrinsic muscles of both eyes, and in one of these the autopsy showed extensive sclerotic changes in floor of the fourth ventricle and aqueduct of Sylvius. The author urges the importance of distinguishing between nystagmus and nystagmus-like twitchings. Both may be seen in the same patient at the same time. Nystagmus occurred in 12 per cent. of the cases and nystagmus-like twitchings in 46 per cent. The former owes its importance

to its relative rarity in the other cerebro-spinal diseases whereas the latter is fairly common, and moreover may be found in health. . . Papillary signs, including hippus, Uhthoff passes as infrequent and insignificant. M.

The Surgery of the Prostate Gland.—MR. M. R. BARKER (*New York Med. Journal*, Dec., 1905), in a communication on this subject, says that much time intervenes from the commencement of a prostatic hypertrophy, until without complications the prostate becomes so large as to occlude the urethra. During this slow enlargement the gland is very susceptible to cold and wet, which often produce acute congestive attacks; these recur again and again with increasing frequency until at last a physician has to be called in to pass a catheter. Having done so, he should recommend the immediate removal of the enlarged prostate. The operation of perineal prostaticectomy which Mr. Barker recommends has under these favourable circumstances almost no mortality. Whatever operation is done there are three important points to remember—minimise the loss of blood, let the operation be as short as possible, and avoid traumatism to the utmost extent. In Mr. Barker's operation a large curved perineal incision is made; the sphincter ani muscle is separated from the central tendon; and the latter is drawn forwards. In this way the membranous urethra is exposed, opened, and a tractor passed into the bladder. By drawing on and raising the handle of this instrument the capsule of the prostate is brought well into view, and is opened by two lateral incisions, and the gland separated by blunt dissection. Any bands are divided by a special combined cutting and crushing clamp devised by the author. Two drainage tubes with gauze packing are left in either side of the wound, and a catheter is tied into the bladder, the cut sphincter carefully re-united to the central tendon, and the wound closed. The catheter is changed daily, the drainage tubes are removed at the end of 48 hours, the patient is allowed to sit up on the second day, and to be out of bed for a short time on the fourth. The author has treated thirty cases with one death, an old man of 73, who had led a catheter life for over six years. The tractor is Mr. Barker's own design, he claims that it is less likely to tear the bladder wall than the instruments usually used in perineal prostaticectomy. G.

The Clinical and Pathological Importance of Chronic Pancreatitis.—MAYO ROBSON (*Edin. Med. Journ.*, Dec. 1905), in an address on this subject, lays stress on the importance of an early diagnosis, before glycosuria supervenes, in order by suitable treatment to prevent much suffering and a fatal termination. Histologically, chronic inflammation of the pancreas may be divided into three varieties:—(1) Chronic interstitial interlobular pancreatitis, in which the normally obscure lobules become distinctly defined; (2) chronic interstitial interacinar pancreatitis, in which the gland becomes tough rather than hard, and is not nodular; (3) cirrhosis of the pancreas the final stage of (1) and (2.) In (1) glycosuria is rare and not till the glandular tissue is destroyed. In (2), diabetes occurs early, and may be fatal before cirrhosis is well marked. The frequency with which an inflammatory enlargement of the head of the pancreas is found, when operating for gall-stones in the common duct, has led Mayo Robson to the conclusion that far the commonest cause of disease is obstruction of the pancreatic duct, with damming back and infection of the secretion. The reason why gall-stones in the common bile duct do not always produce pancreatic inflammation are:—(a) Large gall-stones may never reach the pancreatic portion of the duct. (b) The bile ducts and pancreatic ducts may have separate openings into the duodenum. (c) The duct of Santorini occasionally is the principal outlet for the pancreatic fluid.

In 62 per cent. of all cases the bile duct is completely embraced by the pancreas. A gall-stone passing through such a duct sets up chronic pancreatitis, which in its turn from obstruction to the bile flow will lead to the persistence of jaundice after the stone

has passed. This explains the so-called chronic catarrh of the bile ducts. Chronic pancreatitis may also be caused by (a) obstruction to the pancreatic duct by a growth in the ampulla of Vater, impacted pancreatic calculus, or stenosis after ulceration; (b) direct extension of duodenal catarrh; (c) the toxins of enteric, influenza, tubercle, syphilis, &c.; (d) direct extensions, as from chronic gastric ulcer, or malignant disease of the pylorus; (e) following the acute variety; (f) cystic disease of the pancreas. All the above causes produce interlobular changes in the fibrous tissue and are benefited by operative interference. The etiology of the interacinar variety of pancreatitis is obscure; it is probably due to an abnormal state of the blood. The onset of chronic pancreatitis varies with the cause. No single symptom can, however, be relied on as being diagnostic of the disease, but the author thinks that special stress can be laid upon the progressive wasting, the usual presence of jaundice, the dyspeptic disturbances, the pancreatic reaction of the urine, and the result of chemical examination of the fæces. Physical examination, especially under an anæsthetic, may reveal tumefaction of the head of the gland. The temperature is usually not raised. Glucose in the urine is not a common symptom except in advanced cases. In the differential diagnosis of chronic pancreatitis, the most important conditions to consider are cancer of the head of the pancreas, cancer of the common bile duct, cancer of the liver, gall-stones in the common duct, and chronic catarrh of the bile ducts. Chronic pancreatitis has also been mistaken for malaria, and pernicious anæmia. Preventive treatment aims at removing the usual causes of chronic pancreatitis. If the symptoms persist, the cause should be dealt with by operation. A thorough exploration of the whole length of the common bile duct and head of the pancreas is necessary. If no obvious removable cause can be found, drainage of the infected bile and pancreatic ducts should be secured by cholecystostomy, or cholecystenterostomy. When duodenal catarrh with ulceration is the cause, gastro-enterostomy is advisable. Results: Of 102 operations performed by the author on patients whose pancreatic trouble was the chief disease, 96·1 per cent. were followed by recovery. S.

On the Treatment of Venereal Ulcers and other Skin Affections by the Continuous Application of Heat.—DA ULLMAN (*Blatter f. Klin. Hydrotherapie*, November, 1905, No. 11) contributes a lengthy article on this subject. After review of the ordinary methods in vogue for the treatment of venereal sores and gummata, by means of powers, ointments, and strong antiseptics, he remarks that in many cases these fail owing to the necessity of the patient continuing active, and the consequent neglect of and disturbance in the treatment. Even under most favourable circumstances the cure of these affections may require a considerable time. He then deals with the treatment by means of the continuous application of heat. This method has been before the profession for many years, but has not met with general adoption owing to the complicated apparatus required. Ullman, however, states that comparatively simple forms of hydrothermic regulations can now be employed, and claims that by their use very favourable results will be obtained, many chronic ulcers that had resisted all former treatment healing up within a few days. He attributes the good result to the hyperæmia induced, and particularly recommends the treatment for deep-seated skin lesions. M.

NOTE.—A summary will appear each week in the following sequence:—

- 1.—"Recent Medical Literature."
- 2.—"Recent Surgical Literature."
- 3.—"Recent Gynecological and Obstetrical Literature."
- 4.—"The Recent Literature of Anatomy, Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

THE INTERNATIONAL CONGRESS OF MEDICAL ELECTROLOGY AND RADIOLOGY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I am requested by Prof. Doucer, the General Secretary, to ask you to kindly insert the following notice, if possible, in the next issue of your journal:—

"The Third International Congress of Medical Electrology and Radiology, which for certain reasons was not held at Amsterdam in 1905, will be held this year at Milan from the 5th to the 9th of September. Further particulars will be shortly announced. Information as to membership can be obtained from Dr. Herschell, 36 Harley Street (Correspondant du comité directeur pour la grande Bretagne)." 36 Harley Street, W. I am, Sir, yours truly,
GEORGE HERSCHELL.
January 6th, 1906.

LINCOLN'S INN.—There is as yet no established remedy for leprosy. The serum so confidently advanced some time back has failed to answer its purpose. Isolation is the only practical way known to us of dealing with this terrible malady. The definiteness of the causative bacillus, however, makes it more than probable that not many years will elapse before leprosy is brought within the control of scientific medicine.

A. B. REYNOLDS (Burton).—Sanatorium treatment will undoubtedly save a proportion of sufferers from tuberculosis, and restore them to the community as useful workers. It is practically useless, however, if broken-down and advanced cases. Then, it must be remembered, many of those who have benefited go back to an environment of poverty and other conditions unfavourable to a continuance of a high standard of health.

MEDICAL ATTENDANCE AT THE LAW COURTS.

M.D., M.R.C.P.—The dislocation of medical practice caused by the attendance of medical men at the Law Courts is well known to the judges and barristers; and the latter, in agreement with the solicitors of the case, generally do their best to minimise the inconvenience which may arise. Our correspondent, therefore, should place his position before the latter, and request the favour of being only summoned to attend at the last moment necessary for his evidence.

GENERAL PRACTITIONER.—Adenoids are very rare in late life. A case, however, has been recorded in an old man of 70 years. **JOHN B. TOPPS (Manchester).**—If your friend has the L.S.A. Lond., he is perfectly entitled to put "Physician" on his brass-plate, although he may not call himself Doctor. All this illustrates the absurdity of our many-ported system of qualification.

DR. CALDWELL is thanked for his communication, which we hope to utilise in an early number.

FIFTH YEAR'S STUDENT.—The small handbook, by Dr. Herbert French, of Guy's Hospital, entitled, "Medical Laboratory Methods and Tests," would, we think, answer your requirements.

MR. L. B. M.—You will find your enquiries answered on referring to our editorial columns, present number.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 10th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Mr. J. Cantile: Clinique. Surgical. 5.15 p.m. Lecture: Dr. G. H. Savage: Climacteric Insanities.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.). 5.15 p.m. Meeting.

THURSDAY, JANUARY 11th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Annual General Meeting. The President (Dr. W. Alexander): Valedictory Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Lecture: Mr. L. Mummery: Some Problems in Morbid Physiology.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.).—6 p.m. Chesterfield Lecture. Bullous and Vesicular Eruptions; I, Urticaria; II, Pemphigus; III, Pompholyx; IV, Varicella.

FRIDAY, JANUARY 12th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Mr. L. McGavin: Transverse c. Inguinal Colotomy. Mr. A. I. Pinches and Mr. E. M. Corner: Further Cases of Torsion of the Omentum. Dr. A. E. Garrod and Dr. Langmead: A Case of Associated Malformations including Transposition of Viscera.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelms Street, W.C.).—4 p.m. Clinique. (Eye.)

Vacancies.

Middlesex County Asylum, Napsbury, near St. Albans, Herts.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

York Dispensary.—Resident Medical Officer. Salary £120 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

County Borough of West Ham.—Plaistow and Dagenham Hospitals for Infectious Diseases.—Resident Assistant Medical Officer. Salary £200 per annum, with rooms and board at Plaistow Hospital. Applications to the Medical Superintendent, Plaistow Hospital.

Bristol Royal Infirmary.—Pathologist, Bacteriologist, and Director of Clinical Laboratories. Salary £250 per annum. Applications to W. E. Budgett, Secretary and House Governor.

National Hospital for the Paralysed and Epileptic, Queen Square, Bloomsbury, London, W.C.—Resident Medical Officer. Salary £100 a year, with board and residence. Applications to Godfrey H. Hamilton, Secretary.

County Borough of Burnley.—Medical Officer of Health. Salary £500 per annum. Applications to Peregrine Thomas, Town Clerk, Town Hall, Burnley.

University of Birmingham.—Demonstratorship in Anatomy. Salary £175 per annum. Applications to Geo. H. Morley, Secretary.

Chester General Infirmary.—House Surgeon. Salary £100 per annum, with residence and maintenance in the house. Applications to the Chairman of the Board of Management.

Appointments.

BOYLE, H. EDMUND G., M.R.C.S., L.R.C.P. Lond., Honorary Anaesthetist to the Paddington Green Children's Hospital.

DICKSON, FRANCIS HENRY, M.B., Ch.B. Edin., Junior Assistant House Surgeon at the Stockport Infirmary.

GAUNT, J. P., L.R.C.P. Edin., M.R.C.S., District Medical Officer to the King's Norton Union.

JAMES, WALTER TIMOTHY, M.B., Ch.B. Edin., District Medical Officer for the Aberayron (Cardiganshire) Union.

SMITH, H. WATSON, M.B., Ch.B. Aberd., Second Assistant Medical Officer to the Durham County Asylum, Winterton, Ferryhill.

THOMPSON, GEORGE WILLIAM, M.B. Edin., F.R.C.S. Eng., appointed Ophthalmic Surgeon in charge of Out-patients at the French Hospital, Shaftesbury Avenue.

WAUGH, GEORGE ERNEST, B.A. Cantab. M.D., B.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Hospital for Sick Children, Great Ormond Street.

Births.

MENNELL.—On Jan. 5th, at 57 Holland Park Avenue, London, the wife of Zebulon Mennell, M.B., of a daughter.

Marriages.

CHATTERTON-AITKEN.—On Jan. 4th, at St. Margaret's, Westminster, William Chatterton, M.D., of Penshurst, to Ethel Mary Aitken, daughter of the late Robert Aitken and of Mrs. Aitken, of Bromley, Kent.

POLLOCK-JAY.—On Jan. 5th, at Felixstowe. Major C. E. Pollock, R.A.M.C., son of the late A. R. Pollock, of Paisley, J.P. for the county of Renfrew, to Winifred Mabel, youngest daughter of C. E. H. Jay, late of the War Office, of Glenesk, Felixstowe.

Deaths.

CONDELL.—On Jan. 1st, at Guildford, Julia, widow of the late William Condeall, M.D. and F.R.C.S., formerly of Baslow, Derbyshire.

KINGDON.—On Jan. 5th, at 31 The Broadway, Westminster, during sleep, John Abernethy Kingdon, F.R.C.S., late 2 Bank Buildings, Lothbury, in his 78th year.

LUND.—On Jan. 8th, at Fern Hill, Pendleton, Manchester, Mary Crockett, aged 45, the dear wife of Herbert Lund, F.R.C.S.

PAINE.—On Jan. 6th, at Bournemouth, George Reuben Robins Paine, M.R.C.S., L.R.C.P., late of Lympstone Devon.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25 0s. 0d.; Half Page, 12 10s. 0d.; Quarter Page, 6 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXII.

WEDNESDAY, JANUARY 17, 1906.

No. 3.

NOTES AND COMMENTS.

The Election of 1906. As we go to press the nation is still in the throes of a great political struggle. The General Election of 1906 is likely to prove one of the most memorable in our modern history. Although the returns are not yet complete, it is abundantly clear that the balance of power will incline heavily in the direction of the democratic, as opposed to the conservative section of the community. One of the direct consequences of this change of governmental aim and principle will inevitably be a greater attention during the next few years to social legislation. It is with that aspect of the election that the medical profession is concerned. With politics pure and simple we are naturally not concerned. With the legislative handling of scientific medical knowledge, on the other hand, we are deeply and universally interested. For that affects the moral, the physical and to a great extent the economic well-being of the community.

Parliamentary Candidates and Temperance Legislation. WHAT, for instance, could go down deeper into our inner lives than the question of temperance legislation? But who would venture to say that Parliament during the past generation has been guided by the authority of medical science with regard to that vital matter? Apart from economic considerations, there is the purity of the alcoholic beverages sold to the public. Broadly speaking, good, pure and well-matured ale, wine and spirits do little harm to the consumer, whereas raw, adulterated and new drink spell organic disease, misery, crime and death in the largest of capital letters. If it be found impossible to make men temperate by Act of Parliament, it is nevertheless comparatively simple and easy to reduce the evils to a minimum by insisting upon the liability of the publican to supply a sound article to his customers. Meanwhile, a good start has been made by the legal decision that if a man asks for brandy he is entitled to receive grape brandy and not a distiller's substitute.

Candidates and Physical Deterioration. THE official Parliamentary report upon physical degeneration has furnished the basis of much future industrial and general hygienic legislation. In a sense, it covers the whole ground of the relation between

medical science and Parliament, inasmuch as it deals with the social product of pre-existing faulty conditions. The educated medical man studies symptoms in relation to their causes. When faced with a picture of national deterioration, of lessened stature, of shortened lives, of increasing lunacy, in a word, of a dwindling national standard, both moral and physical, he sets himself to consider the causes of so vast a malady. Will the Parliaments of our generation be wise enough to call in the medical profession to their Privy Council, or will they leave so obvious a step to our children or our grandchildren?

Parliamentary Candidates and Vaccination. YET it is well to recall the other side of the picture. We, the citizens of 1906, have at least one great heritage from our grandfathers. We no longer see every second or third person in the street seamed and pitted with small-pox; we no longer pay a vast annual toll of suffering, disease and death at the demand of that dread malady. Small-pox is preventable, and has been practically prevented—thanks to the immortal genius of Jenner and the common sense of the British Government. Yet there is probably hardly a parliamentary candidate at the present election who has not been heckled by the anti-vaccinationists, who would fain have their countrymen at the mercy of uncontrolled small-pox, rather than have the sacred liberty of the subject invaded. In this case the reasoned and deliberate verdict of medical science has been adopted by the legislature with magnificent results. Yet even here their views have been seriously flouted by the creation in recent years of that hybrid crank, the "conscientious objector." Clearly we want more representatives in Parliament to express current medical opinion whenever it may be necessary or desirable.

Acute Alcoholic Poisoning. FROM the *South African Medical Record* we learn of an interesting and tragic case of acute alcoholic poisoning. It appears that in a drinking saloon on the Rand a number of men were discussing the capabilities of a man with regard to the quantity of alcohol he could drink at a sitting, and one of the disputants wagered an opponent five shillings that he could not drink a bottle of gin straight off. Thus challenged, the

man took up the bottle and drank the contents in two draughts. Almost immediately he became unconscious, and within a few hours he died, in spite of all that could be done for him. It is hardly needful here to animadvert on the folly of these proceedings, both on the part of the challenger and the challenged, but such sudden unconsciousness and rapid death from imbibing a large quantity of spirit are rare, and, as the man seems to have been in good health, they appear to show the intensity with which alcohol can act as a poison on some constitutions.

LEADING ARTICLE.

CORONERS AND SPECIAL PATHOLOGISTS.

ON the 11th instant the long-expected decision of the Metropolitan District Auditor of the Local Government Board was published with regard to the legality of certain charges made upon rate-payers by Mr. Troutbeck, the Westminster Coroner. The question is one of great importance to the general practitioner, as that official's innovations not only deprive him of a legitimate source of professional income, but in addition brand him in the eyes of his neighbours as a man of inferior standing and unfitted to give trustworthy medical evidence in a court of law. Mr. F. B. Cockerton's decision affects the interests of a vast number of medical men in England, Wales and Ireland. As such, it will become a topic of universal discussion amongst practitioners in the countries mentioned, whose hopes were not unnaturally fixed upon the Auditor's appeal. Mr. Cockerton, however, seems compelled by some antic of fate to have the making of momentous decisions thrust into his hands. If we remember aright, it was his famous surcharge that ushered in the education struggles which for years past have vexed the legislature and convulsed the country. When compared with national education the question of the duties of coroners and the rights of medical men may seem somewhat small and parochial, but the fact of any such disproportion by no means does away with the necessity of close examination of the less as well as the greater decision. In a sense it is to be hoped that medical men will all become "passive resisters" if any serious attempt be made to enforce the letter of Mr. Cockerton's reading of the various Coroners Acts. But there is a long interval between the decision of a public official in chambers and the reversal of relations established by long usage between coroners' courts and the medical profession. The Government must indeed be strong that will deliberately rouse the hostility of a powerful profession by imposing upon it disabilities which are incapable of moral justification, even though they may be, as Mr. Cockerton thinks, strictly in accordance with the letter of the law. That the last word has been said in this matter we should be loth to believe. The right of appeal against the decision remains, and there is every reason to anticipate that it will be exercised to its utmost

capacity by the British Medical Association, the body that has been instrumental in bringing the whole matter within the range of practical politics. It was shown at the inquiry that some hundreds of medical men in South London were affected by Mr. Troutbeck's policy. Further, it was stated that during a period of twenty-two months, Dr. Freyberger, his favoured henchman, made *post mortem* examinations and gave evidence in no fewer than 862 cases, for which services he received fees amounting to £1,767. The main legal contention of the objectors was based on the Coroners Act of 1887, which said that if deceased had not been seen during life or immediately after death by a qualified practitioner "the Coroner may call in a medical man in actual practice in or near the place where the death occurred to make a *post mortem* examination, and to give evidence at the inquest." Dr. Freyberger lives near Regent's Park; that is to say, miles away from Battersea, Putney and Wandsworth, so he can hardly be said to practise "in or near" the Westminster Coroner's district, which includes those districts. Yet the opposite view was advanced by the counsel for the London County Council, which seems to have taken up the cudgels for Mr. Troutbeck, if not, indeed, to have initiated and supported consistently his obnoxious policy throughout. Fortunately Mr. Cockerton is obliged, under the provisions of the Public Health Act, 1875, if required to do so by any party interested in the inquiry, to make a written statement of the reasons for his decision. This fact he mentions in his published decision, which we give in another column, and for which we ask the earnest and careful consideration of every medical man in the kingdom, no matter what his professional position. The whole affair presents in miniature a faithful picture of the encroachments that have hitherto been allowed on all sides to sap the legitimate income of the medical man. Here the attack appears to have been instituted by certain medical members of the London County Council, that is to say, by public men to whom we should naturally look for protection and good guidance. Whether that surmise be firmly founded or otherwise, we have no hesitation in calling upon the Local Government Board to deal with this matter fairly and squarely, both in the interest of the public and of a not unimportant profession. The new President of the Local Government Board, Mr. John Burns, if called upon to decide this dispute will have an excellent opportunity of adjudicating upon a subject which must have become more or less familiar to him in his former experience as a member of the London County Council.

SIR GEORGE SCOTT-ROBERTSON, who has won a Conservative seat for Free Trade in Central Bradford, is famous for his heroic defence of Chitral, when he was besieged by Sher Afghal and Umra Khan's troops in 1895. Born in London in 1852, he was educated at Westminster Hospital Medical School, and entered the Indian Medical Service in 1878. He served throughout the Afghan campaign of 1879-80, including the siege of Sharpur, and afterwards became British Agent at Gilgit.

NOTES ON CURRENT TOPICS.

Puerperal Fever in Manchester.

MANCHESTER is one of the few—if not, indeed, the only—large city that provides accommodation at its isolation hospital for cases of puerperal fever. Although a fever hospital may not be an ideal place for the treatment of women soon after confinement, it is very much better that they should be received where proper nursing and medical facilities are to be had than left in their own homes without either, and it seems almost a corollary to the notification which the law demands and the increased employment of midwives which the law encourages that some such arrangement should be made. One good result likely to follow is that puerperal fever can now be studied under conditions that lend themselves to scientific accuracy, and from a paper by Dr. Gordon, of Manchester, published in *Public Health* this month we already learn a remarkable fact. Thirty-seven cases of puerperal fever admitted to the Isolation Hospital were examined with a view to causation and it was found that twenty-three had been under the care of midwives and fourteen under medical practitioners. In all the former there had been no operative interference, the first symptoms of the disease did not show themselves till four to eight days after delivery, and in practically all the cases the organism found was bacillus coli. On the other hand, in all the fourteen cases attended by doctors there had been operative interference, the incubation period was rarely over forty-eight hours, and the organism was a streptococcus, occasionally mixed with bacillus coli. If these observations can be taken as approximately typical of what occurs generally it would seem that puerperal fever without operative interference is very rare in medical practice, but very common in that of midwives, and also that the application of forceps and such obstetrical manipulations should be avoided as much as possible, and when performed should be accompanied by scrupulous antiseptic precautions.

Copper Sulphate and Water Supplies.

WE have had occasion in these columns to refer from time to time to the reputed value of copper sulphate in the purification of town water-supplies, and we are interested to notice that Dr. Howard Jones, medical officer of health for Newport (Mon.), has described in *Water* the first application of the treatment in this country. Three reservoirs supplying his town were treated with copper sulphate on the lines suggested by American experience, and the results are said to have been entirely satisfactory. There can be little doubt that the effect of this disinfectant varies largely according to place and circumstance. In Manilla, which is now, of course, under American administration, there was a scare of cholera in October owing to the occurrence of some cases in the area from which the town derives its water-

supply. The authorities experimented with copper sulphate solution in their reservoirs to see how far it would be possible to keep their water free from germs. It was found, however, that they could not kill the comma-bacillus with any strength under 1 in 150,000, and then it took four hours to do so. This being so, it was not deemed wise to employ the treatment as it certainly could not be pronounced safe to allow people habitually to drink the metal in so concentrated a solution. Another reason assigned was that copper sulphate might act as a disinfectant in the alimentary tract, and that by its means the evacuations might be passed in sterile condition, which, considering that the septic tank system of sewage disposal was used for the town, would hardly conduce to efficiency in working. We confess ourselves that we should need to be strongly persuaded of its necessity before we should consent to supplying the inhabitants of a town with a solution of a metal instead of pure water. At present we know little about chronic copper poisoning, but there is a good chance of our learning a great deal if the plan were widely adopted.

Women's Brains.

THE advocates of women's suffrage, who seem to be rendering themselves rather unpopular at political meetings just now, will find a scientific basis for the faith that is in them if they read a lecture given by Dr. Bernard Hollander last week. Discussing the relative sizes and shapes of the male and female brain, the lecturer showed that though a woman's brains was slightly lighter and smaller in circumference than man's, yet this did not show that her intellectual capacity was less, but merely that her capacity for all the energies was not equal to man's. The portions of male brain most markedly different from those of the female were the ones representing force, energy and animal passion, while woman's brain was better developed as regards the parts concerned in the feelings and emotions. Woman, in fact, was not mentally inferior to man; she was only dissimilar. Comforting, however, as this view may be to the fair sex who seek to battle in the same field as man, it is sad to reflect that those persons who exhibit most force and energy, and, perhaps, sad to relate, even animal passion, are the ones who are most likely to win in the long run.

Telephones and Medical Practice.

THE relation of the telephone to medical practice is forcing itself upon the attention of practitioners of all ranks. This modern system of communication places the medical man at the mercy—so to speak—of mankind at large, in addition to the vagaries and semi-official appeals of his patients. A consultation in the daytime is followed up by a question through the telephone at night, as to how to meet this, that, or the other symptom, and the time imperatively necessary to the medical man for rest, refreshment and

recreation is remorselessly taken up by the chatter of gratuitous business. The patient receiving advice through the medium of the telephone exchange as a rule does not expect to pay any fee in return. The only way out of the wood will be for the medical man to draw up strict rules to meet the situation. He will not undertake, for instance, to answer telephonic communications personally. Any professional advice given by telephone will be charged for as an ordinary consultation. Unless a strong stand be taken at the outset of what will undoubtedly become an almost universal means of social communication, the medical profession will find themselves one day placed in a false and invidious position in the matter.

Formalin Sole.

THE bad French which usually figures on the menus of public dinners and restaurant suppers is likely to be seriously threatened as the orthodox terminology of those invisible artists—the chefs. If this were the only danger apprehension would not run high, for the French menu is perhaps the most exotic form of snobbery that was ever planted on British soil. It is certainly a reproach to the insularity and good sense of John Bull that he has given way to the Parisian innovator so far as to consent to eat kickshaws for his steaks, and *bœuf à la mode* for his native roast. The solid resistance which the bullock's rump presents to the jaws and digestive juices not only gives a sensation of elation to the hearty diner of Anglo-Saxon stock, but—together with the playing-fields of Eton—may be classed with the factors that overthrew the Corsican at Waterloo. But *nous avons change tout cela*, and, unfortunately the late Committee on Physical Degeneration missed an important link in their chain of evidence by not regarding this *voilà face*. This time the change in dietetic parlance is to come from the scientific quarter, and chemistry is to take its rightful place in the ordering of gastronomy. It appears from the report of a trial for adulteration held at Worship Street Police Court recently, in which a firm was fined the exorbitant sum of 20s. for adding 41 grains of boric acid to each pound of its sausages, that when the pot is called black it considers it a defence to refer to the sable character of the kettle. Not only are 41 grains of boric acid added to a pound of sausages by one firm, but meat is by another washed with formalin, and the same chemical is used to preserve the dainty flavour of the sole. A medical witness referred to the last as a matter of common experience, but admitted that the sole should be so classified that the purchaser might be made aware of the fact. He suggested "Formalin Sole," as an appropriate designation. Are we in future to find ourselves set down to eat Borated Beef, Cupric Peas, and Condied Chops? Or will the enterprising dairy-

man advertise "Are you rheumatic? Try our Salicylic Milk?" These matters are in the lap of the gods.

Horse-Flesh Sausages: a Humour of the Election.

NOT long ago a London sanitary inspector seized some sausages and obtained a conviction on the ground that they were made of horse-flesh. The sequel now comes in the proposal that the Public Health Committee of the Paddington Borough Council shall consider and report on the action of the local sanitary inspector who seized certain German sausages, exhibited at a committee-room for political purposes, after being told they were not for sale, which sausages were ultimately rescued, with the consent of Mr. Plowden, magistrate, by their owner, Mr. Chiozza Money, the Liberal candidate for North Paddington. This novel kind of election ammunition, it appears, was intended to appeal to the reason of electors, by furnishing an object-lesson in the food of protected countries. It was not of the same category with electoral eggs.

"Optology" and the General Election.

MR. ARTHUR GREENE, of Norwich, has done a service to the profession in drawing attention in a letter to a contemporary, to the necessity of medical men impressing on candidates for Parliament their views with regard to the Bill which the British Optical Association is endeavouring to pass into law. We understand that there are two Bills being promoted of almost identical import, one by the British Optical Association, and the other by the Society of Chemist-Opticians, with the support of the Spectacle-Makers' Company. The latter Bill is to be introduced into the House of Lords next session by no less a person than Lord Goschen. The object of both Bills is to give a legal status to sight-testing by opticians. There is no need to tell medical men of the dangers of allowing even the most expert "sight-tester," ignorant of everything relating to the anatomy, physiology, and pathology of the eye, to prescribe lenses. It is necessary, however, to impress a sense of these dangers on all possible members of Parliament, and to explain to them, as Mr. Greene puts it, that the seller of spectacles has just the same claim to be protected in his practice of ophthalmology as the dealer in trusses to be established as a specialist in the treatment of hernia.

The International Medical Congress, 1906.

THE Congress is to be held in Lisbon in April next, and already medical men in these countries are beginning to discuss the question of attending it. It is said that the Organising Committee is sparing no pains to render the Congress free from those faults which gave rise to complaints on previous occasions, and that the Portuguese Govern-

ment is giving all the aid in its power. There is no doubt that the inherent difficulties in the way of an international congress are very great, and the question arises whether they are such as can be surmounted. In the first place there is the difficulty due to difference of language, which necessarily interferes with the interest of the discussions. There are few, if any, medical men who can intelligently follow the spoken word in more than two or three languages, but in an international congress the languages are as many as there are nationalities represented. It would hardly make matters easier to insist on all communications being couched in one of a limited number of "official" tongues, since such a regulation would shut out from all participation many of the most competent contributors. A lesser difficulty, but one which has caused much annoyance in the past, is that of arranging the specialties of study which shall be represented by independent sections. We learn from a contemporary, for instance, that "the most prominent representatives of laryngology in Great Britain and Germany have declared their intention of taking no part in the Congress," since laryngology is not to be dignified by a separate section! This is an example of the difficulties which lie in wait for an organising committee, difficulties which, moreover, are much more formidable in the absence of any permanent executive.

Indian Native Women and British Troops.

It is curious to note the want of perspective shown by sentimentalists who seek to reform our morals in so many directions. The practice which they condemn in one profession they condone under other guises in various sections of society. Vivisection, for instance, is a crime in the scientific laboratory, but is right and proper when practised for purposes of sport, personal adornment or mere food and clothing. The Contagious Diseases Acts were crushed out of existence in the United Kingdom by a knot of noisy faddists who preferred the hidden cancer of syphilis to the express and official control of prostitution. What have these worthy persons to say to the treatment of female natives by our Army authorities in India? Is it or is it not a fact that the British military authorities connive at a system which keeps native women practically enslaved to the vices of our soldiers? The British troops in Asia are riddled with venereal disease, the tax for which falls upon the taxpayer at home. If official control be necessary for native women in or near barracks or camps in India, let it be, at any rate, of a nature that will bear the full light of inquiry and afford public information.

School-Children of Tender Age.

THE question as to what age school is desirable for children lies at the very foundation of a rational system of education on hygienic principles. It is with pleasure, therefore, we learn that the Board of Education have had under consideration the

attendance at public elementary schools of children under five years of age. It has been, wisely, as we think, decided to reconsider the advisability of laying before Parliament the Minute which has been proposed for modifying the system of grants in respect both of children under five and of the other scholars in public elementary schools. It is of importance to note that this decision involves a reconsideration by the Board of the way in which a certain amount of relief can best be afforded to those areas where the burden of the education rate is especially heavy. Our views upon this matter have been clearly and emphatically stated. Briefly, we regard the attempt to instil book knowledge into infants as fallacious in theory and dangerous in practice. The brain of the infant has quite enough to do in acquiring the concrete facts of its environment without wandering into a topsyturvy region of abstractions.

PERSONAL.

MR. A. W. MAYO ROBSON, F.R.C.S., has been appointed to represent the Royal College of Surgeons of England at the International Medical Congress, to be held at Lisbon in April next.

MR. JOSEPH MANSENGH PALMER, F.R.C.S.I., has been sworn in as High Sheriff for Armagh.

DR. EDWARD THOMPSON, late member for North Monaghan, informed his former constituents that he would not be a candidate for the representation of the county at the present Parliamentary election.

DR. C. F. HUTCHINSON, who was elected representative of the Rye division at the by-election in 1903, is standing again in the Liberal interest. As a member of the House of Commons, he steadily supported the interests of the medical profession. He rendered special service by introducing the Public Health Bill to provide security of tenure for medical officers of health.

THE first lecture of the course of military instruction for civilian medical practitioners (with a view to the formation of a reserve force) will be delivered at the West London Hospital on January 20th by Surgeon-General Keogh, Director-General of the Army Medical Department.

DR. V. H. RUTHERFORD, who is a Liberal candidate for the Brentford Division of Middlesex, was formerly Medical Officer of the Newcastle School Board. He stood for a Yorkshire constituency recently.

ST. GEORGE'S HOSPITAL, London, will suffer a great loss in the forthcoming resignation of Sir William Bennett, K.C.V.O., who in one capacity or the other has been connected with that Institution for more than thirty years.

SIR WM. JOB COLLINS, M.D., Lond., F.R.C.S., formerly chairman of the London County Council, has been elected by the constituency of St. Pancras, West, London, as a Liberal member of Parliament for that Borough.

MR. F. BOWERMAN JESSETT F.R.C.S., was elected President of the British Gynæcological Society at the annual General Meeting on Thursday last. He occupied the Presidential Chair of the Society during the year 1893.

A CLINICAL LECTURE

ON THE

ESSENTIAL NEPHRITIC HÆMORRHAGE.

BY
Professor SCHÜLLER,
Vienna.

[SPECIALLY REPORTED FOR "THE MEDICAL PRESS."]

THE following cases may be selected to illustrate the difficulty of diagnosing essential hæmorrhage. Whilst there are many among us who are greatly concerned about this difficulty, another section maintains that the disease is only a modification of nephritis, which may be unilateral as well as bilateral. Whichever of these opinions may finally prove to be correct, the evidence at the present time is in favour of an inflammatory change of some kind in the kidneys, with the resulting "essential hæmaturia." The more closely these complex symptoms are watched the conviction grows that the morbid changes are, *sui generis*, of a badly differentiated disease from nephritis.

Each individual observer has a similar complaint that so few accurate descriptions are given that no true judgment can be formed as to whether operative or expectant treatment should be adopted. Suffering from this painful conviction of our lack of knowledge, Schüller expressed his belief that the following cases would be of interest to the profession in forming an opinion on the subject.

CASE I.—M. T., æt. 21, shoemaker, with a good family history, enjoyed perfect health up till August in 1903, when a cough commenced with an exhausted state of the body; no appetite, but sometimes pain and smarting on micturition. The urine was sometimes cloudy and tinged with blood at this time. Three days after this invasion he was received into hospital where he remained for three months. In spite of every care in the analysis of the urine nothing but erythrocytes and a corresponding number of leucocytes could be found—never casts or cylinders—only the proportion of albumin corresponding to the amount of blood present; neither could the tuberculous bacilli be detected though carefully explored.

With perfectly clear and healthy urine and the patient expressing himself as perfectly well, he was discharged on November 5th, 1903, as cured. For five weeks he performed his duties as shoemaker, when suddenly without any cause the hæmaturia recommenced without any other phenomenon than general weakness.

He was again received into hospital on January 1st, 1904, with the following report of his condition at the time:—Medium height, small boned, muscles fairly well developed, with moderate panniculus adiposus; face pale, but no œdema. Arteria radialis soft, pulse 84, rhythmical tension and fulness rather below normal, but cardiac area and sounds normal. Thorax flat; no pathological change to note, and no undue tenderness anywhere about the lower part of the thorax and commencement of abdomen. The right kidney is distinctly enlarged to the size of a man's fist, smooth surface, movable on respiration and easily palpated. The quantity of urine 1400 cubic cm., reddish colour, and reaction, sp. grav. 1018, albumin 0.4 per cent., but no sugar. The sediment contained numerous red blood corpuscles, epithelial cells, granular and hyaline cylinders, comprising 6 to 8 in the microscopic field. In all the preparations no tuberculous bacilli could be discovered. Sterile urine contained no bacterial germs, though many crystals of oxalate of lime were present.

The cystoscope was applied five days after admission with great difficulty, as the patient was irritable and very restless. With this instrument the bladder was found to be healthy and no abnormal condition could be observed at the entrance of the ureters into the organ. An effort was subsequently made to examine

the ureters, but this was found to be impracticable from the sensitive condition of the patient. On January 5th, at 11.58 a.m. 4 grains of indigo carmin were injected into the region of the gluteal muscle under aseptic conditions. At 12.6 the urine drawn off by catheter was slightly blue, a minute later it was darker blue; at this period the cystoscope was inserted to observe the colour of the urine entering the bladder from both ureters, which had a dark blue stream entering from each alike, about 12.17. From this date till January 14th, the urine was periodically examined without discovering anything abnormal; but the hæmorrhage still persisted, notwithstanding careful dieting and confinement to bed.

On January 15th, the temperature rose to 37.8. Over the site of one of the subcutaneous injections he complained of severe pain, where an intra-muscular infiltration had been induced by the fluid. On the 16th this was freely laid open with the discharge of pus. After this the temperature fell to 36.7, but the hæmaturia still persisted. Bed and diet with the administration of styptics were still persevered with, though disappointing in effect. The urine still contained cylindrical and was examined every day for tuberculous bacilli, but none could be found.

The radiograph gave no assistance—no stone or altered condition could be discovered in either of the kidneys.

On the 18th the patient was sponged over with ether, and the cystoscope again applied under this form of semi-narcosis. The mucous membrane of the bladder was observed to be abraded in parts, but not bleeding. The right ureter on this occasion was discharging blood into the bladder, but the left was emitting clear urine. The blood when compared with freezing point of blood taken from the vena mediana of the arm was 0.55. The excessive anæmia demanded some operative interference although no exact diagnosis could be arrived at, as no calculi were present, as proved from X-ray examination. Nothing now remained in the diagnosis for elimination but tumour, tuberculosis, or inflammation of the right kidney.

On January 30th, Zucker-Kandl determined to operate. Ether narcosis was performed, and an inclined incision made over the region of the right kidney, which was easily reached by the small amount of fat present in the capsula propria and the absence of any other thickening. The kidney was then carefully dislocated and found to be increased in all its dimensions, both poles greatly thickened, but no really active morbid condition could be observed. The surface was somewhat irregular, of a livid colour, and intensely injected. Tubercle or abscess was not present. On incising the capsule at the convex edge it could be easily separated from the cortical structure, which was granular on the surface and livid at the poles where the tissue was soft and friable. After resecting the entire capsule, the kidney was returned to the abdomen and the wound closed with three series of stitches, supplied with proper drainage, and finally suitably bandaged.

Next day, January 31st, no fever, though dull and heavy; neither was there any vomiting.

February 1st, no abnormal temperature, pulse 94, urine 450 grammes, cloudy, containing blood, but neutral in character. The albumin was slight with a few cylinders present and a large quantity of epithelium.

On the 2nd, still afebrile, takes milk freely, and drainage tube removed; urine passed 1,100 grammes

of a hæmorrhagic colour, cloudy, acid and sp. gr. 1012; the albumin was small in quantity with a sediment of cylinders and epithelium, and the freezing Δ , when compared with the median artery = -0.90° Centigrade.

February 3rd.—Afebrile, pulse 96, wound healing by first intention, milk diet, "Preblaner" water, quantity of urine, 1,200 grammes, and slightly hæmorrhagic.

February 5th.—Urine 1,400 grammes, of a golden colour, slight sediment, very little blood with here and there granular and hyaline cylinders.

February 6th.—Stitches removed, milk and farinaceous diet, egg and "Preblaner" water. Urine 1,400 grammes, with a small quantity of blood and cylinders as seen by the microscope. Albumin is almost negligible, urea in 1000 parts equal to 14.560 grammes, and $\Delta = -0.92^{\circ}$ C.

February 7th.—Urine 1,600 grammes, still clear, and patient convalescent.

February 8th.—Urine 1,000 grammes, and wound almost healed.

February 9th.—Urine 1,300 cubic centimetres.

February 10th.—Urine 1,000 c.c.m.

February 11th.—Urine 1,700 c.c.m.

February 12th.—Urine, 1,700 c.c.m.

February 13th.—Urine 1,950 c.c.m.

During the latter dates no blood could be detected by the microscope although cylinders still existed with a quantity of amorphous uric acid. By the 15th the patient was able to take his ordinary food, walk about, and felt well.

March 6th.—Urine clear, sp. gr. 1014, no albumin or sugar present, acid reaction, slight sediment, no erythrocytes or cylinders, but a few squamous epithelial cells with amorphous uric acid were present. No tuberculous bacilli could be found at any time. He was dismissed from hospital on the 9th.

Living far from town, the patient sent urine for analysis, which invariably gave the same result.

On July 5th he returned for examination.—Urine straw colour, slightly cloudy, neutral reaction, sp. gr. 1016, no albumin, no sugar, slight sediment, with a few squamous cells, amorphous urates, but a large number of bacteria for the first time made their appearance. This is an interesting case of unilateral hæmaturia, which had existed for a long time without any symptom beyond the periodic attacks of hæmorrhage, and a few cylindrical cells without albumin to guide the clinician in his diagnosis of the disease. The operation, however, demonstrates that a severe chronic condition of the parenchyma of the organ was present. In the literature on essential renal hæmorrhage recurring, protracted bleeding has been described by many writers on the subject. Wagner, who had a wide experience, affirms that the cause is due to chronic nephritis, which Naunyn and Israel confirm by obtaining a shrinking of the kidneys after long continued bleeding. We may, therefore, take it as proved beyond doubt that the so-called essential hæmaturia is nothing more than chronic nephritis. It was of the utmost importance to discover whether the preceding case suffered from unilateral or bilateral inflammation of the kidneys. On this point we have not the operation on the second kidney for ocular demonstration, but we may assume from the rapid convalescence and non-recurrence of hæmorrhage that the other kidney was unaffected.

Israel, in his clinical work on the subject, confirms the unilateral opinion advanced in this case, as the speedy recovery after the operation was proof to him that the second kidney was not affected. The principal question still remains to be answered: Was this a case of Bright's disease? If only one side were affected it could not be according to earlier diagnosis, but Edebohls tells us that he met with unilateral morbus Brightii nine times out of 29 cases. On the other hand, Kimmel found, after sounding the ureters of 100 cases, and examining the secretion from each, that Bright's disease was always bilateral.

From these contradictory opinions it would be

unwise to dogmatise. The correct diagnosis is not an easy matter, as may be seen from the following.

CASE 2.—A. K., was examined on October 6th, 1903. According to his own history he was *æt.* 35, engaged in the Customs and was always healthy till one and a half years ago, when he noticed his urine dark and bloody-looking, but this soon cleared up. He noticed pain occasionally in the right side that radiated up to the right shoulder. He consulted several medical men, who examined him with the cystoscope, and concluded that nothing less than an operation would cure him.

On his reception at hospital his kidneys could not be palpated, the right being very tender. The cystoscope was applied and the bladder found in a normal condition, but a plug of blood closed the orifice of the right ureter. The ureters were catheterised; the left had clear urine with traces of albumin, but no nephritic elements. Floridizin reaction was negative, although 0.005 grm. was injected. The right emitted no urine as it was stopped by a coagulum that could not be removed. The albumin in the left ureter and the clot in the right demanded another examination, but the patient left town and was not seen again for seven months.

On his return he was feeble, weak and bloodless from the constant loss; also complained of loss of sight. The muscles were weak, but had a large quantity of panniculus adiposus, temp. 36.7° pulse 68, respirations 24. The radial artery was well filled and tension high. The face and mucous membrane of the mouth were pale; lungs normal and heart tones clear, with second sound distinctly accentuated. Spleen and liver were not enlarged. Kidneys could not be palpated, the right being still very tender. The urine had a flesh colour, sp. gr. 1024; albumin $1\frac{1}{2}$ per cent., sediment, red blood corpuscles, some resembling leucocytes with hyaline casts.

Notwithstanding careful dieting the bleeding still continued. Quantity of urine 1,200 cubic centimetres. Seven days after admission the cystoscope was inserted and bladder found normal. The Segregator revealed bloody urine from both kidneys, both sides gave $1\frac{1}{2}$ per cent. of albumin, and both sides had casts in the fluid. Besides these morbid changes, retinitis albuminuria was present.

He was confined to bed, put on strict diet, with suitable drugs, but left hospital after a few weeks' residence and died a few weeks later of uræmia.

Here we had at first unilateral hæmaturia and colic without albuminuria or casts, which appears to have existed for $1\frac{1}{2}$ years according to history. After this period the disease becomes progressive and both kidneys become involved with a chronic nephritis, albuminuria, casts, and finally uræmia, two years after the first appearance.

CASE 3.—The next case teaches how careful we must be in determining which side the blood is coming from, as it was first found on the one side and then on the other. Another peculiarity is that the bleeding commenced in the twenty-second week of the last five pregnancies, but persisted in the last.

The patient was *æt.* 31, had had four children without any bad symptoms; but with the next five hæmorrhagic urine was observed about the 22nd week of pregnancy. During the intervals the urine appears to have been normal, and no pain or discomfort about kidneys. After the ninth pregnancy the hæmorrhage and the urine persisted. The cystoscope was applied and located the hæmorrhage to the right kidney. Before this Prof. Israel diagnosed the blood to be coming from the left kidney during pregnancy, with hypertrophy of the left ventricle and lung affection, for which he recommended baths, &c. The hæmorrhagic urine persisted for a year and three-fourths after the ninth pregnancy, as post-partum hæmorrhage with varying intensity. The private attendant discovered wandering kidney on left side, but radiology was negative. She went to Carlsbad for a few months, but without benefit to herself.

On her return two eminent surgeons examined her

with the Luy's instrument, and the segregator gave the following results:—

RIGHT URETER.
Urine clear or slightly yellow; reaction acid.

$\Delta = -1.49$
Albumin, 2 per cent.
Quantity per hour 15 c.c.
Sediment after centrifuging Nil.

LEFT URETER.
Urine cloudy, flesh colour. Reaction acid.

$\Delta = -1.57$
Albumin 1 per cent.
Quantity per hour 45 c.c.
Sediment after centrifuging. A large number of red corpuscles, epithelium from the canaliculi, pelvis of kidney, but no tubercle bacilli.

The orifice of the right ureter was normal, but there was a red area around the left orifice.

Two months later she consulted Zucker-Kandl, who describes her as anæmic, moderately nourished, both lungs moist rales, cardiac area increased, second pulmonary sound accentuated, radial artery, full tension normal, pulse 94, no glandular swellings, abdomen fuller than thorax, but flabby, fatty and having many old striæ. Right kidney greatly enlarged, soft and tender with irregular surface. Left kidney not palpable. A litre of water drawn from the bladder was flesh coloured, cloudy, sp. gr. 1009, reaction acid, $\Delta = -0.74$, small quantity of albumin, no sugar, and total urea 1,131 grms.

With the cystoscope the bladder and orifices of ureters were normal; Luy's segregator gave the following:—

LEFT URETER.

Quantity in 35 minutes—
35 cubic centimetres,
flesh-coloured, cloudy,
and highly acid.

Albumin, small quantity,
but not exactly measured.

$\Delta = -0.54$
Sediment, a large quantity
of blood, no casts, no
tubercle bacilli.

Urea, 0.738 per cent.

RIGHT URETER.

Quantity in 25 minutes—
35 cubic centimetres,
clear or slightly yellow,
feebly acid.

Albumin only a trace,
could be detected.

$\Delta = -0.48$
Sediment, no blood except
a few erythrocytes;
much epithelium, but
no bacilli.

Urea, 0.891 per cent.

Here is a case that controverts the theory of a unilateral inflammation. It commences with the left side after a period of bleeding, but the right kidney soon enlarges and becomes hæmorrhagic, while the left appears to recover or a sort of alternating state is established with every variety of modification.

CASE 4.—Here is another case that recently came under notice. A male, æt. 33, always healthy till 14 months before reception into hospital. Early in the hæmorrhagic attack he was examined carefully, and the blood found to be coming from the left kidney. After a course of treatment he went to Carlsbad to undertake the "Kur" where he improved. About ten months after he returned to hospital with hæmorrhagic urine. He looked well, of a strong build, no excessive panniculus adiposus, although the mucous membrane was pale; but otherwise no outward signs of any internal disease. Neither of the kidneys could be palpated, nor were they tender on pressure.

The urine was flesh-coloured, daily quantity 1,500 cubic centimetres, sp. gr., 1014, reaction acid, centrifuged, traces of albumin, many red corpuscles as well as white ones, epithelium from the bladder, but no casts or tuberculous bacilli, though often examined.

The cystoscope revealed no morbid changes in canal, prostate, or bladder. Hæmorrhagic, urine was slowly running out of the left ureter, flesh-coloured and $\Delta = -0.68$, by segregation polyuric albumin in sediment, and red blood corpuscles. He was again advised to go to Carlsbad, where he improved, but the cure was only temporary, as the hæmorrhage recurred shortly after his return home.

In all these cases we have no evidence of inflammations to adduce as the cause of the hæmorrhage; neither albumin nor casts. Yet we assume in the absence of tubercle that some inflammatory process is present as the exciting cause. The hypothesis is borne out in

some of the cases where albumin and casts have both appeared before the exitus. The intervals or pauses that occur stand in the way of a dogma in this direction, although this difficulty is relieved by assuming that there is a variation in the condition of the nephritic tissue itself. Israel assumes that congestion is the governing cause of the hæmorrhage, or possibly a diffuse nephritis without albumin or casts in the secretion due to the altered condition of the tissue. We may therefore conclude that essential hæmaturia, in the absence of all pathological demonstration, is a symptomatic form of nephritis occurring in one or other of the kidneys alternately, although it may sometimes be bilateral without albumin or casts. If essential hæmaturia be inflammatory as suggested, should operative means cure it? Zucker-Kandl has put a few cases on record disproving this theory. For example, a young man, æt. 17, consulted him for hæmaturia. He had enjoyed good health, had had scarlet fever when ten years of age, and had nothing to account for the hæmaturia. He was confined to bed for two months and was prescribed suitable medicines, but still the hæmaturia persisted. Cystoscope and separation by segregation proved the blood to be coming from the left kidney, although there was a slight trace of albumin coming from the right ureter.

He resolved to decapsule the left kidney, and, strange to say, two days after the operation the urine was quite clear! the bleeding ceased and has not returned again, but albumin has taken its place and constantly appears in the urine. Here the operation cured the bleeding, but has aggravated the albumin. Is the albumin interchangeable? We cannot say the operation has cured the patient, but it has changed the secretion. It is therefore doubtful if the nephritis still exists or is merely modified.

There is another important point in this case that should not be passed over without notice.

While Zucker-Kandl was decapsulating the kidney he excised a portion of the cortex for microscopical examination. Störk, who examined the section, found glomerulitis, proliferous and nephritic hæmorrhagic. This only confirms the assumption that the morbid phenomena are the result of inflammation, but how this inflammatory change is brought about no reasonable cause is forthcoming, as its progress is strange and unusual.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's number will be by Charles B. Maunsell, M.B., B.Ch., F.R.C.S., entitled "Indications for Operation in Appendicitis."

ORIGINAL PAPERS.

RESPONSIBILITY OF CRIMINAL INEBRIATES: MEDICO-LEGAL PROBLEMS OF INEBRIETY.

By T. D. CROTHERS, M.D.,
Editor, *Journal of Inebriety*, &c., &c.

THE startling revelations in the scientific world are repeated in some degree in the sudden opening up of a new territory of medico-legal science, the jurisprudence of Inebriety. Within five years the question of the mental soundness of the inebriate and his capacity to act or reason normally has been raised with increasing frequency in a great variety of criminal and civil cases.

To-day there are hundreds of persons awaiting trial or sentence for crime committed when poisoned by alcohol. There are hundreds of business contracts disputed and contested by law made when the parties were intoxicated. There are hundreds of wills whose validity is questioned for the same reason. There are hundreds of divorce suits where the inebriety of

the parties is the vital question on which the issue of the case turns. Grave questions of social science concerning pauperism, idiocy, and criminality turn on an exact knowledge of inebriety.

Although these topics have so recently come into medico-legal notice, and are so complicated with theories and superstitions, yet they are already divided into three distinct theories or points of view.

1st.—The *ethical* and *moral* view, which seeks an explanation of inebriety from the teaching of Scripture and the opinions of theologians and metaphysicians. This view asserts that inebriety is only a phase of moral depravity innate in every life, and one that is susceptible of great growth and development by wilful neglect and gratification of all the animal instincts. Medico-legally, the remedy is severe punishment, increased responsibility, prayer, conversion, and the application of moral suasion. A man holding these views on the witness-stand believes the inebriate, in all cases, fully conscious and doubly responsible for all his acts.

The *second* is the *legal* view, which is practically an outcome or result of the moral theory. It assumes that inebriety is a phase of savagery or the inborn tendency to lawlessness, and giving up of all control and restraint; or the indulgence of the lower passions regardless of society, law, and order. The legal remedy is severe punishment, increased penalties, and suffering. The theory is to develop the higher nature of man by causing pain and suffering in the lower nature. In this way to rouse up the brain and will power to regain control of the animal part. Three hundred years ago Lord Coke held that inebriety always aggravated the offence, and the punishment should rather be increased. This has been the cornerstone of the legal view of inebriety up to very recent times.

The *third theory* is the *scientific and medical* view. This affirms inebriety to be a physical condition, the tendency of which is often inherited and also acquired. That this physical condition is always a disease, a modified or pronounced form of insanity. In other cases it is a positive symptom of insanity, and also that insanity is often a symptom of inebriety. It is a form of brain degeneration that, like other diseases, has distinct causes, development, progress, and decline. It is also urged that the continuous use of alcohol always causes disturbances of brain circulation, and is followed by brain congestion, brain paralysis, and impaired senses. The result of which is incapacity to realise the nature and character of acts, the judgment is defective, and the control is lessened and is not normal. Medico-legally this theory regards the inebriate as diseased and incapacitated to act sanely, to be treated as a sick man and placed under medical and legal care and control until recovery, or for life.

The two first theories assume perfect sanity in all cases of inebriety, and assert that the remedy is to be more severe punishment and accountability to law and society.

The third theory recognises a physical condition, and demands a scientific study of each case before the remedy or treatment can be determined.

Another theory has been asserted, that in some cases inebriety was a vice at first, then later a disease. That in some cases punishment is the remedy, and in others medical care and treatment.

Practically and medico-legally this view assumes a degree of psychological knowledge and power of discernment as to where vice and disease join that is absurd and impossible from any present knowledge. Such a theory defended on the witness-stand is a sad reflection on the intelligence of the witness. Such are some of the theories and standpoints from which the subject of inebriety is approached medico-legally. The urgency and pressing character of these cases bring these different views into greater prominence daily.

While the confusion and doubt of the exact nature of inebriety is evident to every new advance of thought, it is obvious that it is due in a large part to the failure

of physicians to study these cases independently. The dictum of judges, the teachings of theologians, newspaper views, and public opinions are too often the sources from which medical men derive their views. This was very apparent in a contested will case at Trenton, New Jersey, where five medical men testified to the mental capacity of a chronic inebriate who willed his property to a mistress. The judge declared he should act on his own judgment and decide the man unsound and incapable. In a recent case at Scranton, Pa., a man set fire to a church without apparent motive. Three physicians swore to his sanity, although he had delirium tremens repeatedly and was a chronic inebriate. The jury decided otherwise.

The general problems which are presented in these medico-legal cases are, first: Was the person an inebriate, or one who drank spirits to excess at all times or at intervals? If this fact is established beyond question, his sanity and mental capacity may be most reasonably and naturally doubted.

Second.—What was the mental condition and the circumstances of the person at the time of the commission of the act in question? Was he sane? Was the act reasonable and just in its effects and consequences? If not, the first suspicion is strengthened and the insanity of the person must be assumed, and the legal theory must be reversed; the sanity must be proven, not the insanity.

Third.—The medical man has only to gather the facts, and have the reasonable assurance of their accuracy. The limits of scientific study will not sustain any theories of the exact degree of health and disease, and will not support assumptions of boundary lines of responsibility and irresponsibility.

Recently a notable case has illustrated this mediæval spirit of public opinion which insists on judging every inebriate as fully sane and competent to determine the nature of his thoughts and acts. The following is an outline of the case. :—

John H. Swift shot his wife, July 7th, 1887, at Hartford, Conn. In December of the same year he was tried and sentenced to be hung. A year later, April 5th, 1889, the judiciary committee made an exhaustive examination of all evidence and new testimony offered, and reported in favour of commutation. Both houses of the legislature voted to sustain the report, and commute the sentence to life imprisonment. An adverse wave of public sentiment caused the Governor to veto the action of the legislature, which so influenced the members of one body that they failed to sustain their former vote. Hence Swift was hung April 18th, 1889. Swift was a chronic inebriate and had been drinking to great excess for weeks before the murder. The defence claimed that Swift was incapable of deliberation and premeditation at the time of the crime, from the effects of continuous intoxication. No medical testimony was called. The prosecution claimed premeditation, malice, and full comprehension of what he was doing. The judge reiterated the legal fiction that an unsound or insane mind is always one that cannot determine between right and wrong. Popular opinion voiced by the press insisted on sharp accountability, irrespective of every fact and circumstance, and clamoured for Swift's death in the same unreasonable spirit that urged the execution of witches less than two centuries ago.

A review of the facts in this case will show the judicial blunder and injustice in the execution of Swift.

The hereditary history showed that Swift's grandfather was an inebriate, his father was mentally defective, and his mother suffered from nervous shock for months before he was born.

John H., the prisoner, was a weakly child, and when one year of age fell out of a chair, striking his head, and became unconscious. He was under a doctor's care for brain fever for some time, then recovered. When about three years of age he began to suffer from nasal hæmorrhages, which came on at irregular periods. At six years of age he had an attack

of scarlatina, and these hæmorrhages greatly increased from this period. At times they were so severe as to require the aid of a physician, the attacks lasting from an hour or more to half a day. When eight years of age they grew less frequent and of shorter duration, and finally disappeared. After puberty, they returned and came on at intervals until death. While in gaol two severe attacks occurred. Somewhere about five years of age he suffered from severe night sweats, which continued up to puberty; frequently they followed the nasal hæmorrhages, and generally they appeared after any excitement or special exhaustion. At puberty they disappeared, and severe headaches came on. He complained of the latter all his life, but the excessive use of spirits for the last two years seems to have covered up this symptom. These headaches often preceded the nasal hæmorrhages, and in many instances followed them.

For a period of three years, ending in the murder of his wife, Swift led a life of great irregularity; working from time to time and being discharged for intoxication and incompetence; then spending his time at low saloons, playing the piano for spirits. He grew more and more incompetent and was unable to keep any place long. For four months before the murder he drank to great excess, and was discharged as crazy and on the borders of delirium tremens. He spent several nights in the woods drinking with boon companions. During the year before the murder, the drink paroxysms were followed by three distinct suicidal attempts; one a few days before the murder, in which he swallowed laudanum. After these drink paroxysms he suffered from acute headache, for the relief of which medical aid was called. When stupid from intoxication he would strike his head violently against the floor and show signs of brain pain and distress. Sometimes he came home at night, but always intoxicated. Then he would not be seen for weeks. During the three weeks immediately preceding the crime he was stupidly intoxicated, going from one concert saloon to another, and occasionally coming home at night and going away early in the morning. On the night before and day of the murder he was wildly excited from drink, and seemed suicidal and on the borders of delirium tremens. The evening of the murder he watched for his wife to pass a certain point in the street where he could see her. From her ante-mortem statement Swift met her and inquired if she would forgive and live with him, to this she replied, "No." He then said, "You must die," and shot her fatally. He then ran up an alley and tried to shoot himself, without success, the lock of the revolver failing to work. He was arrested, and later denied all recollection of the event. He reiterated this statement up to death, and claimed he could not realise why he had killed the woman of all others he loved so dearly. Exactly what he did or said before the crime is disputed. The prosecution claimed that Swift bought a pistol and affirmed that he was going to kill his wife if she did not live with him. The defence showed that he was wild and suicidal, also intensely excited for days before, and acted and talked like an insane man. When arrested he was suffering from well-marked syphilitic eruptions, and for a long time his mind was like one recovering from alcoholic excess. From this time to the execution he was cool and indifferent, expressed no fear of death and showed no special interest in the efforts made to save him. In gaol and at the gallows he manifested a strange unconsciousness of his situation and surroundings, and although his health greatly improved he remained stolidly indifferent to the last.

A summary of the facts would indicate the following:—

1.—Swift inherited a degree of mental degeneration and tendency to neurotic disease that would naturally develop from the slightest exciting causes. An alcoholic diathesis was present, and nerve and brain enfeeblement that would find in alcohol a most seductive relief. His ancestral history showed the impos-

sibility of Swift's having a sound mind in a sound body.

I conclude with a summary of the facts which seem supported by the strongest evidence presented up to this time.

1.—In all cases of inebriate criminals there is literally mental defect and more or less incapacity to reason sanely or control their acts. An inebriate who does criminal acts cannot be of sound mind. No criminal who is an inebriate is sane, and no inebriate is fully sane, and no criminal can be of sound mind long.

2.—The question for the medical witness to decide is, How far was the prisoner conscious of the nature of his acts; and how far did he have control over his acts in a certain condition when crime was committed?

3.—In a case where crime was committed under the influence of alcohol, the law asks what was the prisoner's mental condition at this time and insists on fixing the boundaries of responsibility and accountability. The law demands that science should go into this penumbra region of sanity and insanity and point out where vice and disease join, and where human justice should punish and where it should excuse as irresponsible.

4.—The scientific man demands that this question of mental condition at the time of the crime should be studied independent of all theories or legal rulings, seeking the facts and their meaning with no hesitation as to effects of such conclusions on the court or public. The scientific man refuses to draw boundary lines of disease and accountability, but insists on minute study and general conclusions based on the probable facts.

5.—Finally, in all these cases the medical witness is called to determine the physiological, pathological, and psychological facts and their meaning. The application of these facts must be made by the court, jury and law.

The medical expert and student of to-day must go beyond the theories of yesterday for the acts on which yesterday's views were based. A newer, larger field opens up to-day, and the facts are more numerous and indicate a clearer, wider view to-morrow.

DIETARY IN DIABETES AND GOUT.

By S. A. ARANY, M.D.,
of Carlsbad.

THE literature of diabetes and gout has, in the last two decades, been enriched by many a valuable treatise dealing with the etiology and symptoms of these two morbi-assimilations. Although symptoms, complications, and the course of both diseases are only too well known to the [profession, and many invaluable investigations and studies have been made to find a cure for these ailments, therapy has not, or at least very little, advanced in the last twenty years. These investigations resulted in the invention of many invaluable medical agents (antipyryn, aspirin, heroin, glycogen), which, however important they may be in other maladies, only mitigate the course of diabetes and gout, so that the only recourse left to the practitioner is to treat these ailments by means of dietary. It is, therefore, of utmost importance to the general practitioner to know what diet will best suit each individual case, and I beg to be permitted briefly to discuss the usual regimen adopted by myself in both kinds of ailments. True, it is a subject on which much has been written and to different effect, so that my way lies of necessity to a great extent over a well-beaten track; yet a man in my line of practice has ample opportunity to observe to what extent these well-known dietary principles are ignored, and the serious consequences the ignorance of them sometimes produces.

The Diet of Diabetic Patients.—I have in this paper no intention to discuss the etiology of diabetes, and I may be permitted to state that I do not make a distinction between chronic glycosuria and real diabetes,

considering them to be different stages of one and the same disease. What is generally called glycosuria is, in my opinion, the early stage of the disease which may and may not develop into the secondary stage, or what is usually called grave or real diabetes. The fact that some cases which come under the practitioner's observation are of a distinctly mild nature, whereas other cases of greater severity show almost different symptoms to the former is no proof to the contrary, as there is just as little, or even less, similarity between the different stages of syphilis, and I do not think anyone will deny that they are stages of one and the same disease. The fact that certain cases coming under observation have a very short course and soon prove fatal cannot be regarded as a proof against this view, it only proves that the primary stage of the disease has been unobserved and thus not attended to, which circumstance has accelerated the development of the disease into the secondary stage. I considered it necessary to make these introductory remarks, as the diet I am advocating varies according to the stage of the disease.

When prescribing a diet to a diabetic patient we must take two facts into consideration, viz., that the diet must be neither too greeneous nor too severe, as the former may prove just as detrimental as the latter. This aim can only be attained if the diet is controlled by frequent urinary analyses and by comparing the patient's bodily weight. The principle of the diet is to prevent the patient from eliminating sugar, and therefore, at the beginning of the treatment, it will be necessary to put the patient on a diet which is entirely free from carbohydrates. In cases belonging to the primary stage such regimen is usually followed by a most striking result: as the tormenting symptoms become alleviated in the first or second day of the treatment the amount of glucose rapidly diminishes, and in the course of two or three weeks the urine becomes free from sugar. This is usually followed by increase of the bodily weight, and patients do extremely well for a certain time to come. However, after a more or less protracted period has elapsed the patient again calls on us complaining of loss of flesh and strength, and general nervousness. On analysing the urine we find it to be free from sugar, which speaks in favour of the fact that the foregoing symptoms are not due to elimination of sugar but to the too great severity of diet. For the diet which has freed the patient from sugar has been also instrumental in restoring his assimilative power of carbohydrates to a certain extent, and in possession of this regained power the patient's system requires a certain amount of carbohydrates. In such cases it will, therefore, be advisable to enrich the patient's diet in this direction. This, however, must be done by gradually increasing the amount of carbohydrates so long as the limit of the patient's assimilative power is reached. Up to this point he will increase in weight and strength, and the urine will be free from sugar; if, however, the limit of the assimilative powers is being exceeded, diabetic symptoms set in.

In cases belonging to the secondary stage the diet is not always followed by so favourable result as in the former cases, as at this stage of the disease sugar is also drawn from the bodily tissue. It will therefore be our duty to keep the patient on a perfectly restricted diet as long as the urine does not contain acetone and diacetic acid. However, as soon as these products appear in the urine a further withdrawal of carbohydrates may easily give rise to diabetic coma, and it becomes eminently advisable to make some dietary allowances in the shape of a small amount of carbohydrates. This should be continued until the urine becomes free from acetone and diacetic acid. When this stage is reached reduce the carbohydrates, and I have found that some patients can better stand 1 or 2 per cent. sugar than traces of diacetic acid.

Having dealt with the diabetic diet in general, I shall now proceed to discuss the principal food stuffs in general. At the beginning of treatment we must

exclude carbohydrates from the patient's diet. To do this entirely is, of course, beyond possibility, as even animal food contains a certain amount; this is, however, of trifling percentage in comparison with vegetables. The patient's diet therefore must chiefly consist of animal food, viz., meat, fish, eggs, milk, butter and cheese.

(a) Meat of any kind with the exception of liver may be indulged in. Preference may be given to fat kinds of meat, *i.e.*, beef, pork, lamb, goose, whereas veal, fowl, and venison are supposed to be less nutritious in diabetic cases.

(b) Fish of any kind, fresh or tinned, may form part of the diet; moreover salmon and eel as well as sardines are generally looked upon as very valuable food stuffs for diabetics.

(c) Eggs play a prominent part in the diabetic diet, first on account of their great nutritive value, and secondly, there are so many ways of preparing eggs that patients do not get so easily tired of this kind of food. Eggs mix most readily with different fat stuffs—as butter, bacon and oil, which in their turn seem to be very well assimilated by most patients and are supposed to be a nutritious food in diabetes.

(d) Milk in smaller quantities as an addition to the tea and coffee may be indulged in even in the severest cases, whereas greater quantities of milk may only in the primary stage of the disease be prescribed. In cases belonging to the secondary stage sour milk, butter milk, as well as milks which have been freed from sugar, may be well recommended.

(e) Butter and fat stuffs in general are as a rule well tolerated, even in excessive amounts, and are apt to increase the patient's bodily weight. The same applies to cheese, and especially to the fat kinds, as cream cheese, Gorgonzola, Rochfort.

A purely animal diet, however advantageous it may be otherwise, is apt to give rise to digestive troubles of various kinds, and it is therefore advisable to add some vegetables to the former. In spite of the advice of the practitioners in olden days that greens in general may be prescribed to diabetics, modern investigations have shown that even green vegetables contain varying amounts of carbohydrates. It will therefore be advisable to prescribe in mild cases greens in general, whereas in cases of greater severity only greens containing the least amount of carbohydrates are to be recommended. Such are: Spinach, cucumber, sorrel, cauliflower, asparagus, salad, cabbage, tomatoes, and mushrooms. Peas, beans, celery and radish, should not be recommended in the secondary stage, whereas fresh or stewed raspberries, morello-cherries, currants, sour apples, and sour oranges may be indulged in.

The article the patient lacks most is bread, which, in a successful diet must, unfortunately, be withdrawn. Latterly many substitutes for bread have been manufactured by British and Continental firms, the reliability of which, however, is more than doubtful, as most of these preparations, in spite of the re-assuring advertisements of their manufacturers, and also in spite of some medical testimonials, contain a varying amount of starch. In my search for a thoroughly reliable substitute for bread I have been kindly assisted by Dr. Pavy, who called my attention to Messrs. Callard and Co.'s preparations, among which their gluten biscuits may be recommended in the severest cases, as they are perfectly free from starch and are not unpleasant to the palate either. These biscuits, which may be taken with or without butter, I usually prescribe to the patient as long as his urine contains sugar. When free from sugar for some time I replace the biscuits by small quantities of toast, which I increase as long as the urine continues to be free, but as soon as the limit has been reached no further increase must take place. A trial of similar kind may be ventured with other kinds of carbohydrates, *i.e.*, potatoes or rice, rather favourites with diabetics (stolen waters are sweet), but it is very important to start with very small quantities

and stop increasing them as soon as glucose re-appears.

As far as drinks are concerned mineral waters rank highest, and among them the aerated alkaline waters seemed to be liked most by patients, as the carbonic acid contained therein alleviates the excessive thirst and drying of the mouth. These waters may be well taken with lemon juice and sweetened with Saxein, which preparation is by far the most harmless and most palatable substitute for sugar. Among alcoholic drinks wine seems to have a beneficial and stimulating effect in most cases, but special care should be taken to ascertain that the wine be free from sugar. Light Moselle or a mature claret taken with meals and in moderation improve both digestion and strength of the patient. Brandy and whisky are, as a rule, not so well tolerated as wine; in cases of habitual drinkers, however, one is bound to permit a small quantity of these liquors, and my experience has taught me that Martel's or Hennessy's liqueur brandy and one or two whiskies of known reputation are the least detrimental of their kinds. As to the general treatment of diabetes, I would refer your readers to my article of March 29th, 1905, in the MEDICAL PRESS AND CIRCULAR.

The Diet of Gouty Patients.—Ere entering into the discussion of the diet proper, I beg to remark that the diet in question does not refer to typical cases of gout only but is also intended for the various complaints comprised in the collective name of "Uric Acid Diathesis." It is not my intention to discuss the etiology of these complaints, as it is my aim to strictly confine myself to the title of this paper. The comprehension of the dietary principles, however, requires a few explanatory remarks, which I will now briefly give:—The general view held by the majority of the profession is that gouty ailments are due to accumulation of uric acid in the system, the only difference of opinion being, whether there is a faulty elimination or an excessive formation of uric acid in gout? Which ever of the two may be the case, the practitioner's duty will be to prescribe his patient a diet containing as little uric acid as possible. The xanthins are regarded to be the chief producers of uric acid, and therefore it will be necessary to avoid all the food stuffs which contain those substances; such are, first of all, meats of any kind and description containing varying amounts of xanthin bodies, which food stuffs, however, cannot possibly be avoided altogether if we are anxious to maintain the patient's strength. To advise the patient to abstain from meat altogether would be just as great a mistake as not to restrict this article of food at all. Our teeth and digestive organs in general are an unmistakable proof of our being omnivorous creatures, or, in other words, our digestion and assimilation could not possibly manage the additional labour imposed upon them by a purely vegetarian diet, which it goes without saying must be a good deal more voluminous if it is expected to replace the calories of a meat diet. The only thing we can do is to restrict the patient's consumption of meat and to give the preference to those kinds of meat which contain the least amount of xanthins. The meat of the larger animals is as a rule richer in those substances than that of the smaller ones, viz., beef contains more xanthins than veal, mutton more than lamb's meat, and the meat of a hen more than that of a spring chicken. Boiled meat is, according to German authors, less detrimental than roast meat, as the xanthins are supposed to be soluble in hot water, which thus deprives the meat of its noxious ingredients. My own experience has taught me that it is quite sufficient to advise the patient to abstain from butcher's meat and to take fowl and fish in moderation. Besides these, eggs, milk, butter, cheese, vegetables and fruits may be indulged in, whereas broths, sweets and pastry are to be avoided. Weak coffee and tea sweetened with Saxein may be allowed in moderation and the free use of mineral waters ought to be strongly recommended. Alcoholic drinks are best avoided. In cases in which total abstinence cannot be insisted upon, a

very light Moselle or Voelau Rauhenek may be allowed in very small quantities. Under no circumstances should whisky, brandy, port or liqueurs be allowed.

The usual *regimé* I prescribe in gouty cases runs as follows:—

Breakfast.—Porridge, 2 eggs, biscuits or toast and butter, weak tea, coffee or milk.

Luncheon.—Fish, green vegetables, pudding. Bilin or Neudorfer water ($\frac{1}{4}$ bottle of light Moselle or Rauhenek).

Five o'clock.—Milk and toast.

Dinner.—Vegetable soup, fish, fowl, once or twice a week, veal or mutton, greens, stewed fruits without sugar, or sweetened with Saxein, puddings, cheese, fruit, the above-named mineral waters (same quantity of wine).

On this diet the majority of patients do fairly well, although I must admit that a good few of my patients who were total abstainers from meat on their own account were also subject to slight attacks of gout at certain intervals.

From what source the uric acid producing these attacks came, I am at loss to account. This, however, does not prevent me believing that a restricted meat diet is instrumental in producing a great deal of good in gout.

During an acute attack of gout I put the patient upon a purely milk diet, and usually obtain very satisfactory results.

CLINICAL RECORDS.

A CASE OF

RECKLINGHAUSEN'S DISEASE.*

By P. H. PARSONS, L.R.C.S., L.R.C.P.ED.

THE case is one of Recklinghausen's disease—a congenital and multiple fibro-neuromata. J. H., a male, æt. 39, working as a licensed messenger; he is small, thin, poorly developed, with scanty coarse hair. You notice that his voice is rough and hoarse, and that his hearing is defective; that his sight is also failing; he also suffers from what he terms "piles," but what is probably another manifestation of the disease with which he is afflicted. This disease began before birth, that his mother apparently suffered from it and died at the age of 59 from "chest trouble," probably similar to his own; also that his brother, æt. 38, has the same kind of skin affection. He can give no further family history. When he is stripped it will be seen that he is covered with outgrowths of various sizes, some right on the skin surface, some only to be felt under the surface; some large, some small, some painful—exceedingly so—others quite painless to touch, over some of these the skin is red and tender, some are freely movable, others not. There are also patches of colour on the skin, some light, others, chiefly the smaller ones, dark, a large patch may be noticed in the right hypochondriac region. These tumours are fibro-neuromata, and are benign, except for their mechanical action in causing paralyses, &c. There is no treatment of any avail except where possible to remove a growth causing discomfort.

The illustration on page 69 shows very well the site and the varying shapes and sizes of these multiple tumours. There are many more to be seen on the front aspect of the body.

Some Notes on v. Recklinghausen's Disease.

In 1882, v. Recklinghausen described and drew attention to a condition of generalised neuro-fibromatosis or multiple fibroma, which has since been called after him. The disease is congenital, or, at any rate, shows a hereditary predisposition, it having even been found in the fœtus. As the name implies, it consists of a variable and indefinite number of fibromata arising

(* Clinical case shown at the Association of Diplomates of Scotland Meeting, 11, Chandos Street, London, W., December 12th, 1905.

in the sheathes of the nerves in any part of their course, either deep or superficial. Clifford Allbutt mentions a case where he found the visceral nerves affected. The tumours which arise on the nerve trunks may give rise to paralyses, pains, cramps, contractures, or weakness of muscles with all their varied symptoms. The tumours sometimes grow very quickly, and so may vary greatly in size. Amongst them we usually find some of the nature of plexiform neuromata. Coincident with the tumours may be found pigmentation, most frequently as spots chiefly on the trunk and upper parts of the limbs not on the face, hands, or feet, and as patches of a brownish white colour and of very variable size. The spots are not permanent, while the patches usually are. V. Recklinghausen, in his description outlined the following four essential points:

1. Soft fibrous nodules, some sessile, some pedunculated, varying greatly in size and number, scattered over the surface of the body. They may be diffuse and reach enormous size, producing a condition called "elephantiasis neuromatosa."

2. Tumours resembling those of plexiform neuromata may be present on any part of the nerve trunks from their central origin to the periphery. Their variable situation may lead to a variety of symptoms, more especially as they may arise from the nerve roots within the spinal cord or cranium. Superficial painful nodules may be present.

3. Patches of brownish pigmentation of the skin either as small spots or large areas are always present; congenital naevi are frequently present also.

4. There are many variable sensory and motor phenomena resulting from the presence of the nerve tumours, but peculiar mental changes, with loss of intellectual power and sometimes difficulty in speaking are especially characteristic of the disease. The prognosis depends on the possibility of successful removal.

THE OUT-PATIENTS' ROOM.

WESTMINSTER HOSPITAL.

Case of Hysterical Ptosis.

DR. PURVES STEWART demonstrated a case of a young woman, a domestic servant, æt. 25, who had been sent to the hospital with the following history: Two years ago she had anæmia, her eyes then became inflamed, and for several weeks she could not open either of them. The right eye recovered, but she had been unable to open the left eye since. In addition she had occasional paroxysms of difficulty in swallowing. She screamed in her sleep, and had occasional so-called fainting attacks. On examination, the girl had a somewhat preoccupied expression. On elevation of the left eyelid passively, it was found that both visual fields were contracted, more so on the left side, and that the pupils and external ocular movements were normal. The optic discs were healthy. The question arises, Dr. Stewart said, as to the genuineness of the apparent ptosis. On careful examination, it was observed that the orbicularis was habitually contracted on that side, and more particularly that there was no compensatory over action of the frontalis muscle, such as is always present in organic ptosis. In further support of the functional nature of the case, it was found that smell and taste were completely lost, and also that hearing was markedly impaired on the left side. This combination of loss of the special senses—smell, vision, taste, and hearing—Dr. Stewart pointed out, was pathognomonic of hysteria. In addition, the girl showed a characteristic area of cutaneous anæsthesia, implicating the left side of the face, head and neck, trunk, and shoulder, sharply marked off by diagrammatic lines from the remaining normal area. The motor and reflex functions were normal. The chief interest of the case, Dr. Stewart pointed out, lay in the diagnosis between functional and organic disease. It was proposed to treat the woman by a course of isolation, massage, and electricity, according to Weir Mitchell's well-known regime. The prognosis as to ultimate recovery, Dr. Stewart thought, was good, but it was impossible to foretell the exact time necessary for such recovery. An important point to bear in mind, he considered, was that hysteria, contrary to popular opinion among laymen, is not synonymous with shamming; it is a disease as real as cancer or small-pox.

Another Case of Hysteria.

A girl, æt. 17, complained of trembling of the legs and arms of six weeks' duration, and of inability to walk in the normal fashion. On examination, she was a healthy-looking girl, who, when unaware of being observed, showed no obvious abnormality; on the approach of the physician, however, an irregular jerking movement at once started affecting the right arm and both the legs. At the commencement, it consisted of a series of short jerks at the wrist, elbow, knee, and hip, culminating in a violent antero-posterior jerk of the pelvis. These jerkings were paroxysmal with intermissions of complete freedom. On most careful physical examination no abnormality was detected in any of the functions of the body. The application of a Paquelin's cautery to the spine produced immediate cessation of the spasms of the limbs, but the pelvic jerking still persisted when the girl walked, but this, too, was ultimately overcome by holding the point of the cautery half-an-inch from the patient's umbilicus; the inhibitory effect of this prospective new stimulus succeeded in checking the pelvic jerks, inasmuch as had the latter persisted the patient would, as it were, have impaled herself on the cautery. Further treatment, Dr. Stewart said, would consist in segregation

from her old surroundings, preferably by admission to the hospital, in repetition of the local treatment by means of the cautery, and in general mental supervision of the girl. The prognosis, he thought, was excellent, more especially as there was absence of other hysterical stigmata such as the previous case showed.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

FRACTURE OF THE FEMUR WITH MUCH DISPLACEMENT.—Mr. MAYO COLLIER operated on a woman, *æt.* 56, who had been admitted with a fracture of the left femur. The patient had been mounted on a chair engaged in hanging clothes out to dry in a back garden, when, losing her balance, she fell and was found to be unable to rise. She was brought to the hospital and the house-surgeon made a diagnosis of fracture of the left femur. A long outside extension splint was applied. On Mr. Collier's visit to the hospital the case was thoroughly examined and found to be somewhat unusual. A fracture apparently existed below the small trochanter, obliquely upwards and outwards; the upper end of the lower fragment was drawn upwards and backwards below the tuberosity of the ischium, whereas the lower end of the upper fragment was tilted upwards and forwards, and pointed immediately beneath the skin in Scarpa's triangle, threatening to protrude at any moment. Mr. Collier said this was a very unusual condition of things, and demanded immediate operation so as to adjust the fragments with wire. The space between the two fragments was between three or four inches, and no hope of union could be entertained unless the parts were properly adjusted. A large incision was made, commencing immediately below the anterior superior spine, downwards for about eight inches. The tensor *vaginæ femoris* and the *vastus externus* were incised, and the site of the fracture reached. By means of considerable extension and counter-extension the fractured surfaces were adjusted. The bones were drilled so as to carry a thick silver wire, and after this had been securely fixed so as to maintain the bones in firm apposition, the wound was closed, dressed, and the patient returned to bed after the application of a long outside splint with extension. Mr. Collier said that this was a case of extreme gravity, and quite unusual in his experience of fractured thigh. The separation of the parts was much greater than was found in the great majority of cases, and demanded immediate surgical interference; but at the same time, there was some doubt as to recovery. An extensive wound such as had been necessitated, together with a fracture of the thigh in a patient, *æt.* 56, naturally was associated with grave anxiety as to the result.

Happily, in this case the patient bore the operation extremely well, and convalesced uninterruptedly. She is now, within six weeks of the operation, walking about the wards with the aid of a crutch. The limb is little short of its fellow, and promises to be as useful as ever.

PARA-SACRAL EXCISION OF THE RECTUM.—Mr. TEMPLETON operated on a man, *æt.* 66, who had been sent to him by Dr. John Brunton. The history was the following: For several months the patient had complained of pain and feeling of weight in the rectum, especially after the prolonged standing which was necessitated by his occupation—that of a tram driver. Occasional hæmorrhage took place and frequent attacks of diarrhœa, alternating with constipation. The man himself was rather broken down in health,

partly on account of his habits and partly on account of the malady. The circulation was, however, in a satisfactory condition. On examination of the rectum an extensive growth was readily made out extending from an inch and a half above the anus to a strictured point through which the finger could not be passed, this being about three inches from the lower end of the growth. There was considerable ulceration. The sigmoid flexure was pretty well loaded with fæces. No nodules were detected in the liver, though the organ was somewhat enlarged. There was no albumin in the urine. During the week preceding the operation means were taken to completely empty the sigmoid, and for the last two days 10 grains of salol had been administered morning and evening, the diet being restricted so as to produce as little residue as possible. The lower part of the rectum was thoroughly washed out immediately before operation. The patient having been anæsthetised with chloride of ethyl (the anæsthetic being continued during the operation with ether and afterwards with chloroform) was placed on the right side with the buttocks turned over and resting on a pillow. The usual antiseptic preparation of the skin having been performed, an incision was carried from the left posterior inferior spine downwards and inwards, till it reached the middle line an inch and a half behind the anus, this incision was deepened and a few small vessels caught up; the coccyx was then defined and removed. Next the various muscular structures attached to the coccyx and sacrum were freely divided till the space in the hollow of the sacrum was entered. Several enlarged glands were felt here. The rectum was now carefully defined, beginning from above downwards, and the growth was found to extend some four inches in vertical measurement, the posterior wall of the gut being more involved than the anterior. The peritoneal cavity was opened in separating the upper portion of the rectum, and, in order to facilitate the separation from the prostate, the finger of an assistant was retained in the rectum; in this way the rectum from its first portion to the anus was isolated. The upper part of the gut was now drawn down, and brought right outside the wound, and being then completely encircled with a double ligature in two places, was cut across. The remaining portion of the rectum was now completely pulled out of the wound, detached right down to the external sphincter, where it was divided. The hollow of the sacrum was next cleared of all glands. The rent in the peritoneum was closed with fine silk sutures. The ligatured proximal end was next brought out and fixed with fine silk in the upper angle of the wound; the skin being brought together below it. A large drain tube was left at the lower angle of the wound and another passed through the anal aperture. The ligature on the portion of bowel which had been stitched to the upper part of the wound was next removed and a large rubber tube passed well into the gut, so as to permit of the escape of flatus and bowel contents. Iodoform was dusted on pretty freely, and the usual aseptic dressings applied and fixed with strapping. The operation occupied a period of one hour. The patient lost very little blood and his pulse was in a very good condition at the end of the procedure.

Mr. Templeton said that the operation he had performed was justifiable when the general condition of the patient and the extent of the growth rendered it possible. Colotomy, he remarked, was a more or less unsatisfactory proceeding, as the growth is not removed and a very unpleasant condition of the patient is established by the presence of the artificial anus;

this, he thought, applied with great aptness to this particular case as the symptoms were not a source of great annoyance to the patient, and he would have suffered more from a colotomy than from an untouched malignant rectum, though, of course, the latter would have ultimately destroyed his life. Mr. Templeton laid stress on the importance of free removal of the glands and adipose tissues in the hollow of the sacrum. Great attention, he said, was also given to avoid any soiling of the wound by any bowel contents. It would also be noticed that care was taken in closing the rent in the peritoneum, this opening having been an essential accompaniment of the free necessary removal of the bowel. It should be noticed, he said, that before fixing the bowel he had given the gut part of a turn so as to obviate as far as possible subsequent incontinence (Gersuny's principle). He pointed out that sometimes in this operation it was possible to bring the bowel down to the anus, but this was not practicable in the present case, owing to the amount of the gut that had to be removed, and further, the growth was so low down that it was impossible to conserve any of the lower end of the bowel. The object in having the large drain tube in the bowel, he remarked, was to avoid as far as possible the immediate contamination of the wound.

The subsequent progress of the case was satisfactory, and four weeks after operation the patient was convalescent. The bowels now cause him very slight inconvenience, as they act spontaneously each morning

SPECIAL ARTICLE.

THE REPORT OF THE INSPECTORS OF LUNATICS IN IRELAND.—II.

(Concluded from our last Issue.)

THE number of patients discharged from the Irish Asylums during the year 1904 numbered 1,940, of whom only 1,402 are classed as recoveries; 35.9 of the male admissions, and 36.8 of the female; the lowest ratio of recoveries, 12.0, occurring in an asylum, which we learn from Appendix E, is in the opinion of the inspectors "disgracefully overcrowded," and the highest recovery rate, 50.7, was in Killarney, where the inspectors report that the recently provided "accommodation should meet the requirements of the district for some time to come." The moral seems perfectly obvious that recoveries cannot be hoped for under unhygienic conditions, and, to put it on the lowest grounds, it would pay much better to treat the patients under circumstances which would give them a chance of recovery rather than keep them to slide into terminal dementia, from which death only opens a gate of escape from the asylum—and from a charge on the rates. The recovery rate for the two quinquennial periods, 1898 to 1902 and 1893 to 1897 was for the former, 36.4, and for the latter, 38.4, and this drop in the recovery-rate is co-incidental with a gradually increasing condition of ochlesis. The recovery-rate in England in 1904 was 36.6 per 100 admissions, of whom over 6 were general paralytics, who never recover; and the average for the ten years ending 1904 was 37.7.

The deaths during the year were 1,449, an increase of 60—50 more males and 10 more females—on the previous year; the rate being 7.5 on the males and 8.2 on the females, calculated on the daily average number resident. Four of these were by suicide, four by misadventure, and two were killed by fellow patients. The highest death-rate occurred in Sligo, and the lowest in Kilkenny. With this mass of pathological material by which so much might be done to elucidate the condition of morbid brains, it is to be regretted that only 286 *Post-mortem* examinations were held; but the medical staff in most asylums is kept so low it is difficult for men to find time for these examinations, and the want of any laboratory, available for all asylums as in Scotland, where histological research could be carried on, robs us in Ireland of the chief incentive in this

matter. The number of deaths from consumption is returned as 418, or over 28 per cent. of the total; 56 persons died of general paralysis, and 30 from dysentery, colitis, or diarrhoea. Since the year 1890, 16,885 have died in Irish asylums; of these 4,671 were due to consumption, 569 to general paralysis, and 846 to epilepsy. In view of this appalling mortality from consumption, it is really time that some efforts were made to cope with the disease in Irish asylums. The inspectors draw attention to the fact that "the question of the treatment of cases of this disease in isolation hospitals has of late occupied much attention. In dealing with the insane in asylums it is not possible to follow the course adopted with ordinary patients in a hospital."

We heartily re-echo this pious opinion, and wish we had some more tangible evidence of its realization than the mildly expressed view of its desirability. With whom does the initiative lie, and how long are we to be sickened with the record of a holocaust of victims of this preventable and curable disease? It may be as well to draw attention to the fact that of the 9,334 deaths recorded by the English Lunacy Commissioners in 1904, only 1,442 are returned as due to "phthisis." Making every allowance for the higher national death-rate from consumption in Ireland, some explanation is called for as to why the death-rate in Irish asylums should be nearly twice that in English ones. The deaths by violence include one from alcoholic poisoning, and one in which a patient in Cork Asylum, one of six in a room only intended for four, was found dead on the floor from head injuries and a chamber vessel smeared with blood beside him. The coroner's jury quaintly recommended that indiarubber utensils only should be used. The inspectors quite seriously combat the suggestion on the obvious grounds, but fail to clinch it with what would probably have been, to the Committee of Management, the absolutely convincing argument of increased expense.

The record of zymotic diseases is bad during the year, the most serious being a severe epidemic of enteric in Cork Asylum, which attacked over 100 people, of whom 18 died. Dysentery is still unfortunately prevalent in the comparatively modern asylum at Downpatrick, and 50 cases occurred, of whom 11 died. In Richmond, 99 cases of phthisis occurred, and 67 deaths. There were 23 cases of pneumonia with 17 deaths.

The total expenditure during the year amounted to £52,128, odd shillings, and the net expenditure on maintenance to £459,542. Of this the Government paid £181,691 as capitation grant, and £5,110 for maintenance of criminal lunatics in district asylums. This is exclusive of the Youghal Auxiliary Asylum, the accounts of which are published "subject to revision hereafter, as an authoritative copy thereof could not be obtained up to the date of this report." The maintenance in this latter would seem to be somewhat lower than in the District asylums, which seem to be effected by a reduction of the wages bill and the cost of provisions and groceries. The attendants in Irish asylums are, as a rule, poorly paid, and the diet is not over generous as a rule. It does not seem to us that the cost under either heading can be reduced with advantage to the patients, and we search in vain in the Appendix for the minute and elaborate criticism of the administration which the inspectors are wont to furnish local Committees of Management with, and the gently insinuating recommendations for improvement. Have the inspectors, as well as the Resident Medical Superintendent of Cork, been refused access to the Youghal Auxiliary Asylum?

The average cost of maintenance, including repayment of loans, calculated on gross expenditure, was £29 17s. 4d. per head, while the cost, less loan repayments, receipts from miscellaneous sources, and receipts from paying patients, was £23 12s. 10d. The average cost of the Dundrum (Criminal) Asylum patients was £45 9s. 9d. per head.

On the whole the most we can say for the management of Irish asylums during the year is that they have been content to mark time—without any definite progress in any direction.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD JANUARY 12TH, 1906.

The President, Mr. CLUTTON, in the Chair.

MR. LAWRIE MCGAVIN read a paper on
TRANSVERSE *versus* INGUINAL COLOTOMY.

Attention was drawn on the one hand, to the danger of assuming too early that the time had arrived for the performance of colotomy, and on the other to that of its performance too late. Much more might be done than was generally supposed in non-ulcerative stenoses of the rectum by the palliative means, even in cases of severe obstruction, which fact was supported by the report of a case recently under the care of the writer. After discussing the disadvantages of the lumbar and iliac operations, Mr. McGavin gave his reasons for advocating the adoption of transverse colotomy as the routine method; the most important of these being: the firmer support for the belt and plug afforded by the subcostal space, the immunity of the transverse colon to prolapse, the greater simplicity of the operation owing to the mobility of this portion of the bowel, the greater ease with which a sphincter can be obtained, the adaptability of the position of the new anus to the easy and comfortable evacuation of the bowel and the greater facility with which the transverse colon can be reconstituted should occasion arise. Out of four cases of colotomy done by the iliac route, some difficulty of control of the motions and considerable prolapse had been complained of in three, in spite of the belt and pad. Notes of three cases done by the transverse method were read. Two of these cases had been done for fæcal fistulae, and one for dysenteric ulceration of the rectum. In all the colotomy had answered admirably, control being good, prolapse absent, and the general comfort much in excess of that usually gained by the iliac method. The writer considered that an improvement in the operation might be effected by dividing the bowel, closing the distal and drawing the proximal stroma through a broad band of fibres derived from the rectus muscle and permanently suturing it there.

The PRESIDENT said that nowadays he never saw prolapse after inguinal colotomy; he did not even find it necessary to employ any apparatus. As regards the utilisation of the rectus that of course was now the rule in iliac operations.

Mr. HARRISON CRIPPS said that he had performed over 600 inguinal colotomies, but only about a dozen transverse ones. He agreed that lumbar colotomy was now obsolete. There were three difficulties to be contended with after a colotomy. First was the question of prolapse. This was a very rare occurrence at the present day, as it could be prevented by not making the wound too low, by ensuring that no slack bowel was left above the wound, and by taking care to make the opening the right size. Secondly, there was the difficulty of retaining the fæcal matter. An important point here was to obtain a due degree of solidity of the intestinal contents, and in this connection was to be remembered the difference between the contents of the transverse colon and of the sigmoid. Thirdly, 20 to 30 per cent. of the cases were troubled by decomposing mucoid secretion in the distal part of the gut. This secretion could be treated in inguinal colotomies by syringing through, but with a transverse colotomy the distance between the opening and the anus made this treatment impracticable. In conclusion he thought that inguinal colotomy was the operation of choice, and that transverse colotomy should only be done when the obstruction is too high to permit the former operation.

Mr. T. OPENSHAW endorsed Mr. Cripps' remarks.

He would only perform transverse colotomy when the obstruction was in the splenic flexure.

Dr. BROOKS, of Lincoln, asked whether in the latter case short circuiting would not be the better treatment?

Mr. MCGAVIN, in reply, pointed out that anastomosis was out of the question in his cases as the sigmoid was no longer patent.

Messrs. H. IRVING PINCHES AND EDRED M. CORNER read a paper on

FURTHER CASES OF TORSION OF THE OMENTUM.

Case I. was a male, æt. 48. He had a right inguinal hernia for thirty-seven years; a truss had been worn for thirty-three years. The hernia came down whenever the truss was removed; it was easily reduced and never caused any pain. Onset of symptoms with slight pain in the inguinal region, the hernia could not be reduced. The pain increased in severity and the tumour became larger. There was no vomiting, the bowels were opened two days after onset. On the third day the temperature was 99, pulse 102. The tumour was extremely tender, soft and doughy to the touch, irreducible, no impulse on coughing. The lower part of the abdomen and the inguinal region were extremely tender, and the skin was reddened over this area. The tissues felt thickened over the tumour, as if there was some inflammatory lesion present. The diagnosis was torsion of the omentum in a hernia sac. Over the inguinal canal the tissues were found at the operation to be in a subacute inflammatory condition; the hernial sac was thickened. In the sac was a small mass of dark friable omentum twisted upon itself three times. The omentum was not nipped at the internal ring. The tumour was removed. Recovery took place.

Case II. was a male, æt. 45. A left inguinal hernia was present which had only been noticed a few days. A small, tender, hard, irreducible rounded lump of omentum was felt just outside the external ring. The diagnosis was left, direct inguinal epiplocele. A direct hernia was found at operation, but owing to the large amount of subperitoneal fat, the sac was difficult to identify; the omentum was adherent to the sac. The contained omentum was about the size of a walnut and had a stalk. There was a hæmorrhagic cyst within it. It was not strangulated. Although a twist of the pedicle was not seen, there was every physical and symptomatic reason to suggest its presence. This is the only example of possible torsion of the omentum in a direct inguinal hernia.

Two more published cases were quoted, which brings the number of known cases of torsion of the omentum to 57. Clinically the omentum may be in the abdomen above, a hernia alone, or more commonly in both. Two-thirds of the cases were in males, usually of middle age. The hernia was usually an inguinal one, there being no instance on record of the condition occurring in a femoral one.

The PRESIDENT discussed the significance of the words strangulation and torsion and also commented on torsion in its occurrence elsewhere in the abdomen.

Mr. FORBES ROSS asked wherein lay the interest of distinguishing clinically the condition from appendicitis, seeing that the diagnosis could in both instances be decided by operation.

Mr. W. C. SPENCER asked how the diagnosis had been arrived at in the case reported. As to the non-occurrence of the condition in femoral hernias there was no *a priori* reason why this should be so, and in fact he had seen very similar conditions in such hernias.

Mr. PINCHES, in reply, distinguished between torsion and strangulation in that the latter involved constriction by the neck of the hernia. The diagnosis in his case was arrived at by finding an inflamed hernia with extensive tenderness of the abdominal wall in a patient previously suffering from a freely moving hernia.

BRITISH GYNÆCOLOGICAL SOCIETY.

THE Annual General Meeting of this Society was held on Thursday last, January 11th, Dr. Wm. Alexander, President, in the chair.

Dr. SLIMON, Hon. Treasurer, submitted his report and balance sheet for the past year, which showed the Society to be in its usual flourishing condition. A cordial vote of thanks was accorded to Dr. Slimon for the immense amount of labour and care expended during his year of office.

Dr. MACAN, editor of the *Journal and Transactions* of the Society, then read his annual report.

In proposing that a hearty vote of thanks be accorded to the Editor, Mr. JESSETT remarked that under Dr. Macan's charge the *Transactions* had become quite a classical work, not only by virtue of the original papers and record of the doings of the Society, but also because of the abstracts and reviews of Gynæcological work on the Continent and America, and the contributions from foreign gynæcologists he had secured.

Dr. CARTER having seconded the resolution, a vote of thanks for his services was unanimously passed to Dr. Macan.

Hearty votes of thanks were also accorded to the honorary Auditors and to the honorary Secretaries, and the meeting was asked to vote on the election of officers for the year ensuing. The following is the result of the ballot:—

Hon. President: R. Barnes, M.D., F.R.C.P., F.R.C.S. *President*: F. Bowreman Jessett, F.R.C.S. (London). *Vice-Presidents*: T. Gelston Atkins, B.A., M.D., M.Ch. (Cork); William Duncan, M.D., F.R.C.P., F.R.C.S. (London); Bedford Fenwick, M.D., M.R.C.P. (London); H. Jellett, M.D., F.R.C.P.I. (Dublin); R. P. Ranken Lyle, B.A., M.D., B.Ch. (Newcastle-on-Tyne); Sir A. V. Macan, M.A., M.B., M.Ch., M.A.O., F.R.C.P.I. (Dublin); J. Jameson Macan, M.A., M.D., (London); W. H. C. Newnham, M.A., M.B., M.R.C.S. (Clifton); Thomas Oliver, M.A., LL.D., M.D., F.R.C.P. (Newcastle-on-Tyne); Heywood Smith, M.A., M.D., M.R.C.P. (London); R. T. Smith, M.D., M.R.C.P. (London); W. Dunnett Spanton, F.R.C.S. (Hanley). *Hon. Treasurer*: W. H. Slimon, M.D., F.F.P.S. (London). *Council*: S. Jervois Aarons, M.D., M.R.C.P. (London); W. Alexander, M.D., M.Ch., F.R.C.S. (Liverpool); N. T. Brewis, M.B., C.M., F.R.C.P., F.R.C.S.E. (Edinburgh); A. Donald, M.A., M.D., M.R.C.P. (Manchester); T. J. English, M.D. (London); J. H. Ferguson, M.D., F.R.C.P.E., F.R.C.S.E. (Edinburgh); Clement Godson, M.D., M.R.C.P. (London); R. J. Kinkead, A.B., M.D. (Galway); J. Macpherson Lawrie, M.D. (Weymouth); Samuel Lloyd, M.D. (London); J. A. Mansell-Moullin, M.A., M.B., M.R.C.P. (London); F. R. Mutch, M.D., C.M. (Nottingham); John Padman, M.R.C.S. (London); Ernesto Pestalozza, M.D. (Florence); J. J. Redfern, M.A., M.D., M.Ch., M.A.O. (Croydon); Mary Anne Dacomb Scharlieb, M.D., M.S. (London); H. J. F. Simson, M.B., C.M., M.R.C.P., F.R.C.S.E.; J. H. Swanton, M.A., M.D., M.Ch., M.R.C.P. (London); J. W. Taylor, M.Sc., M.D., F.R.C.S. (Birmingham); W. Travers, M.D., F.R.C.S. (London); E. H. Tweedy, F.R.C.P.I. (Dublin); H. F. Vaughan-Jackson, M.R.C.S., L.R.C.P. (Potter's Bar); Hugh Woods, B.A., M.D., B.Ch., M.A.O. (London). *Editor of the Journal*: J. J. Macan, M.A., M.D. (London). *Assistant Editor*: J. H. Swanton, M.D., M.R.C.P. (London). *Hon. Secretaries*: Smallwood Savage, M.A., M.B., B.Ch., F.R.C.S. (Birmingham); Harry Overy, M.B., F.R.C.S. (London). *Auditors*: C. H. Bennett, M.D. (London); F. A. Purcell, M.D. (London). *Trustees of the Property of the Society*: G. Granville Bantock, M.D., F.R.C.S.; R. S. Fancourt Barnes, M.D., F.R.S.E.; Clement Godson, M.D., M.R.C.P.

The retiring President then delivered his valedictory address, an abstract of which we hope to publish in our next.

FRANCE.

Paris, January 14th, 1906.

ASCITES IN WOMEN.

ASCITES in women does not always present very distinctive features. In cases of cirrhosis of the liver, ascites is the same in woman as in man. However, the frequency of the malady is not the same in the two sexes, cirrhosis being observed much more frequently in men. In cardiac affections the difference is slight, but the characters which are special to women, says Dr. Chauffard, are those connected with the Fallopian tubes and the ovaries, and the two great causes of ascites thus derived are:—Tuberculosis and neoplasms. Essential ascites of young girls is an affection which develops without pain in subjects whose general condition is ordinarily satisfactory. There exists also a kind of free and indolent ascites, accompanied by a slight pleural effusion. This ascites is of tuberculous origin, due to tuberculous lesions of the tubes or the ovaries.

It is of importance to recognise the real cause of ascites, as it sometimes indicates the existence of a local lesion which might be removed and the patient cured.

Where the cause is not discovered at the beginning the malady progresses, and when a correct diagnosis is made it is generally too late.

A woman, æt. 40, entered the hospital for ascites. Some time before, the apex of the right lung showed signs of tuberculous softening, and at the same time she suffered from mitral disease. On account of the existence of the pulmonary lesion the medical attendant considered the case to be one of tuberculous peritonitis, and tapped the patient several times. When she went into the hospital Dr. Chauffard, in order to clear up all doubt as to the nature of the liquid, injected a few drms. into a guinea pig. The animal exhibited no signs of tuberculosis. When the uterus and the accessories were examined, a polykystic tumour of the ovary was discovered. The diseased organ was removed, but the woman, already weakened by the malady, succumbed a few weeks afterwards. A fatal issue might have been avoided if a correct diagnosis had been made at the beginning.

In cases of ascites in women, the ovaries and Fallopian tubes should always be carefully examined. However, sometimes by reason of its volume and progressive development a serious error might result. Considered to be a case of pregnancy, the malady is allowed to take its course.

A woman, æt. 22, without any personal antecedents, commenced to feel unwell in the early part of 1904. She lost her appetite, got thin and was constipated, the menses became less abundant, and finally ceased altogether. A doctor called in by the young woman declared that she was pregnant. The patient, continuing to suffer, asked the advice of a second doctor, who gave the same opinion. She entered the maternity hospital in consequence, but there it was discovered that it was a case of ascites and she was handed over to Dr. Chauffard. At this point not only was the liquid found to be very abundant, but also a considerable effusion into the right pleura, which necessitated thoracentesis. The abdomen was also tapped and eight quarts of dark yellow liquid removed. Examination of the uterus showed the os closed, but on each side of the womb two hard and uneven tumours could be felt. Gradually the condition of the patient became aggravated, and phlebitis set in in the left leg, and she succumbed ten months after the first symptoms of her malady. At the autopsy two large tumours of the total weight of three pounds were found connected with each ovary. Microscopic examination revealed the nature of the tumour, which was that of a mixed form of sarcoma and epithelioma.

Malignant tumours of the ovaries, says Dr. Chauffard, offer in general the following characters:—Transverse position, hardness and absence of adhesions; ascites is always present.

The patient should have been operated on at the commencement when she was thought to be in the first months of pregnancy. However, it is not certain that the operation would have been successful, as cancer of the ovaries is a very grave affection, especially so in a young woman, as the malignity of epithelioma in young subjects is well known.

GERMANY.

Berlin, January 14th, 1906.

INJURIES AND DISEASES OF THE HEART FROM BLOWS, ETC.

A PAPER on this subject appears in the *Vierteljahrsch f. gerichtl. Med.*, 4, 1905, from the pen of Dr. Bernstein. The work covers a very large field, the literature of the subject has been gone into thoroughly, and the author has made a collection of ninety-eight cases from which the following conclusions have been drawn:—

1. The heart may be injured by blows on the thorax, with subsequent disease of the heart as a consequence.
2. Why and when this will happen cannot be predicted in any given case, as the accompanying circumstances cannot be predicted.
3. Diseases of the heart may be traced back to preceding blows or other forms of injuries over the thorax.
4. These can rarely be decided on with certainty, mostly with more or less probability. The decision depends mostly on the answer to the question whether a certain form of disease could develop within a certain time.
5. On the whole such occurrences were rare.

THYROID AND THYMUS IN BASEDOW'S DISEASE.

Dr. v. Hausemann has a paper on this subject in the *Berliner Kl. Wochens.* 44, 1905. Although recovery had followed operation on the thyroid in cases of Basedow's disease as early as 1882 (Bénard), it was Möbius who claimed that the disease in question was one of the thyroid gland. This view was arrived at mainly by microscopic examination of the gland. By this it was seen that the stroma of the body differed from that in health, that it was characterised by growth of the parenchyma and increase of the secretory surfaces. The growth of the parenchyma was so excessive that papillary elevation took place in the follicles, and completely filled them. Cystic struma might combine with the parenchymatous struma. The colloid substance in the follicles disappeared completely or was barely visible. In its place a fluid, readily resorbable and occasionally containing mucine, appeared. From this property of the thyroid it was undoubtedly capable of increased activity.

It was incorrect, however, to speak of hypertroidism, as the secretion from such glandular tissue was a changed and abnormal one. Feeding with thyroid had always given bad results in Basedow's disease. Toxic symptoms set up in healthy people by overfeeding with thyroid substance resembled in many particulars those of Basedow's disease. Ehrlich, on the other hand, believed Basedow's disease to be a neurosis, and the change in the thyroid to be secondary.

In all hypertrophic conditions of organs, and so with the thyroid, there was always the possibility that the change was a degeneration. This explained how Basedow's disease could be associated with myxœdema, i.e., hyperthyroidism, with athyroidism. A case of Basedow's disease was treated by mistake with thymus substance instead of thyroid, and with a good result. Similar observations had been made by others, Cunningham, Mickulicz, &c. This led to a more careful study of the thymus in Basedow's disease, and a series of cases was observed in which, along with the struma, the thymus was also enlarged, although during development the thymus gland was near to the thyroid, or later on completely changed its character. The few remaining, the Harsal bodies, showed such degenera-

tive form that there could be no question of functional activity. All known diseases of the thymus of later life were those of the lymphatic system. In the majority of cases the thymus was unchanged in Basedow's disease, i.e., it was met with in its normal atrophic condition. In eight cases that had been examined since 1897 there was enlargement of the thymus in four. The characteristic of these cases was that the thymus was always found in reginary proximity with thyroid. Either the thymus touched the thyroid, or a group of enlarged lymphatic glands lay between the two. All this indicates that a connection can well exist between an enlarged thyroid and the lymphatic system, and especially the thymus gland. The writer is of opinion that the enlargement of the thymus in Basedow's disease is not accidental, but that it is caused by the increased functional activity of the thyroid.

THE HEART IN FRIEDREICH'S DISEASE.

The *Deutsche Med. Zeitung*, 2, 1906, has a reference to the subject. In a girl who died at fifteen, the first disturbance in walking took place when she was nine, and at the same time she had convulsions with loss of consciousness. She was seen when ten years of age; there was then distinct ataxy of the lower extremities, less marked in the upper; Romberg's sign very pronounced, loss of patella reflexes, &c. A year later the epileptiform attacks had become very frequent. Gait and carriage showed the tabeto-cerebellar type. No disturbance of the sphincters. At the heart there was a prolonged first sound, but no murmur. The patient showed sudden signs of pulmonary congestion, and died.

The autopsy confirmed the diagnosis of Friedreich's disease. The most striking feature was the size of the dilated and hypertrophied heart (weight, 480 grammes). The myocardium was pale, the walls of the ventricles were 28 to 30mm. thick. No valvular disease. The microscope showed extensive and advanced myocarditis. The case led to certain conclusions, the first of which was that cases of Friedreich's disease often died of cardiac mischief, chiefly over the myocardium, which developed insidiously. In many cases the heart affection was caused by the same infective mischief that set up the nerve disease, that they were two simultaneous expressions of an infectious or toxic-infection process.

AUSTRIA.

Vienna, Jan. 14th, 1906.

PSEUDO-HYPERTROPHIA MUSCULARIS.

At the Gesellschaft für Innere Medizin, Schlesinger showed a case of pseudo-hypertrophia muscularis complicated with myxœdema which yielded to the thyroid treatment, but the hypertrophia remained much about the same. He related the history of another similar case which was acted on in the same way; it was therefore concluded that two separate causes were fundamentally the origin of the diseases, although a singular coincidence of their concurrence. The body temperature of the children was perfectly normal after two months' close observation. The myxœdema seems to have been the secondary invasion and not of so long a standing as the hypertrophy, there were no changes in the bones and the thyroid treatment acted in a few days after application.

DYSENTERY AND SERUM.

Jehle showed two cases that had suffered from dysentery, whom he had treated successfully with the "Krusse Serum." In both cases one subcutaneous injection of 25 c.cm. obtained from the Vienna state Institute was sufficient to neutralise the dysenteric virus. In describing his method of demonstration on cultures he preferred to use a mixture of serum and the physiological salt solution with a one per cent. of mannit and litmus. The latter should be used till the coloration has assumed a decided blue and the whole sterilised. To determine the flora in a suspected substance about 1 ctm. is poured into the sterilised culture and streak tests taken on agar plates. Within a few

hours the reaction can be decided when bacteria coli are present, as the red transformation, by their acid-forming product as well as the gas bubbles, can be easily determined. "Shiga-Krusa" bodies fail to produce this reaction which allows the culture to retain the blue colour. The great advantage of this method is its rapidity and easily ocular proof by reason of the number of colonies where the morphology stand in striking contrast.

RHEUMATISM Nodosium.

Horn showed a case of nodular rheumatism associated with chorea following endocarditis. Nodular rheumatism is acknowledged as a symptom following rheumatic attacks but never admitted as a primary cause. In many cases of rheumatism we have no fever, no prodroma, and only a vague feeling of pain in the limbs, particularly around joints or sinews, where it is known as periarticular and ligamentus, which are usually symmetrical on both sides of the body. In a similar manner those nodules occur as hard peas, which at first are tender and sensitive but ultimately lose that property and become normal, while they are easily movable under the skin. These nodules are evidently the product of the rheumatic poison deposited in the tendons and ligaments. It seems to be a non-inflammatory product containing fibrillary tissue when examined by the microscope, which subsequently becomes hard and boney in appearance. Therapy has no effect on these nodules, which after four or five weeks undergo a degenerative change in which the boney substance becomes fatty and finally is absorbed.

HUNGARY.

Budapest, Jan 14th, 1906.

At the recent meeting of the Budapest Interhospital Association, Dr. Heller exhibited an unusually interesting case of

AORTIC ANEURISM OF TRAUMATIC ORIGIN.

Though by far the greater majority of aortic aneurisms have their origin in a syphilitic process within the walls of the artery there is little room for doubt that trauma was the sole etiological factor in this case. A labourer was suddenly obliged to carry a very heavy weight, resulting in an acute dilatation of the beginning of the aorta with the tearing off of a portion of the wall. At the same time two aortic valves were torn, leading to an acute insufficiency with dilatation of the left ventricle. The resulting fall in pressure permitted the tear in the aorta to cover itself with intima, but the rest of the wall slowly developed into an aneurism. Microscopically, the picture can be clearly differentiated from a specific process; in the one the elastic fibres of the media are everywhere pushed apart and torn, while in the other, a small-celled infiltration with giant-cells accompanied the nutrient vessels through the media and adventitia, while later portions of the media become necrotic.

Dr. Szajfers discussed the question of

LUMBAR PUNCTURE IN URÆMIA.

The astonishing statement is made by Szajfers, that most cases of uræmia complicating scarlet fever can be cured if treated by lumbar puncture. The technique is very simple. The patient is simply placed in the lateral position and punctured between the twelfth dorsal and the first lumbar vertebra; as soon as the fluid disappears, 5 to 30 grains are aspirated by means of a syringe. The initial and oft-time fatal convulsions of scarlet fever and measles also yield readily to lumbar puncture and a trial in purely renal conditions and in eclampsia is certainly indicated.

Dr. Györi related his experience on the subject of

SUBCUTANEOUS INTRODUCTION OF FOOD.

Hitherto sterilised oil only had he said, proved suitable in the cases under his care. Kalodal, a proteid obtained from meat, had been extensively tried by Györi, and it appeared to be suitable before and after operations in weakened individuals, as it can be readily sterilised and is not followed by pain or albuminuria. Instead of giving a simple infusion of saline solution,

Dr. Györi said he now invariably adds five grains of kalodal in 500 grains of fluid, which he introduces under the skin at two different sites. This can be repeated every six hours, so that the patient receives twenty grains of albumin or 82 calories subcutaneously every day. Since a cachetic individual requires only about 22 grains, the advantages are evident. If an attempt is made to concentrate the solution, small amounts of albumin will appear in the urine, but the amount can be considerably increased by adding kalodal to nutritive enemas, as it is very rapidly absorbed from the rectum. The drug is on the market in sterile solution in glass tubes.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

UNIVERSITY OF EDINBURGH.—ANNUAL REPORT FOR 1905.—During the year the total number of matriculated students (including 385 women) was 3,165, being the highest number reached for twelve years. Of these, 1,500 belonged to the faculty of medicine, 45 per cent. being Scottish, 22 per cent. English, 18 per cent. Colonial, and about 12 per cent. and 5 per cent. from Ireland and India respectively. The number of non-Scottish students of medicine is somewhat higher than in recent years. Among the degrees conferred during 1905 were M.B., C.M., 5; M.B., Ch.B., 192; (including 9 women); M.D., 76 (including 2 women); and Ch.M., 1; while the special certificates in Diseases in Tropical Climates was granted to 77 candidates (including 6 women). Substantial progress has been made during the year with the scheme for the "Improvement and Expansion of the University," in the conversion of the old High School buildings (lately the Fever Hospital) into an engineering and physical laboratory, in doing which it has been found possible to preserve to a large extent the external fabric of the structure. Building operations will be begun early this year on an adjacent site for the erection of the Natural Philosophy department. Although the Carnegie Foundation has so far had little appreciable effect in increasing the number of students, it continues to be noticeable that many who avail themselves of its benefit take out a larger number of classes than they would probably otherwise have done. Among new Lectureships founded may be mentioned those on Disease-Carrying Insects and Venomous Animals, and on Tropical Hygiene, by which instruction is to be given in connection with the newly-instituted Diploma in Tropical Medicine. Extended provision has also been made for the teaching of clinical surgery by the assignment to Professor Chiene of definite duties in that department. Among the changes in the Professorate are the replacement of Professor A. R. Simpson by Sir J. Halliday Croom; the office of Dean of the Faculty of Medicine held by the former is now filled by Professor D. J. Cunningham. The death of Professor Copeland causes the Chair of Astronomy to become vacant; the post is now filled by Mr. Frank Watson Dyson, F.R.S., lately assistant astronomer at Greenwich Observatory. The re-cataloguing of the Library is now practically complete; in the general library 210,000 volumes have been dealt with, and, in addition, several departmental libraries, including that in the reading-room of the Medical Buildings, have also been catalogued. The printing of the whole catalogue will have to be considered as soon as the alphabetical arrangement and cross-entries are completed; meanwhile the printing of an abridged catalogue of some 25,000 volumes, for the use of students, is being proceeded with. Great progress has been made with the extension of the University Union, and it is expected that October, 1906, will see the whole building fit for occupation. A large library, reading and writing rooms, new committee-rooms, new kitchen, and two five courts have been provided. Funds to the amount of £15,000 are still needed to meet current expenditure, and to clear off existing debt.

BELFAST.

PARLIAMENTARY AND MUNICIPAL ELECTIONS.—Medical men, like other mortals, are much taken up at present with electioneering in both higher and lower spheres. Considerable disappointment is felt that we are not to have the promised entertainment of seeing Dr. Henry O'Neill contest the Parliamentary constituency of South Belfast. He had planned to do so, and those who knew his vigorous and outspoken style of debate were assured of a lively campaign, but, unfortunately, the General Election has come too soon for him. He is High Sheriff for the City, and is debarred from standing for Parliament during his year of office. He is, however, standing again for the representation of St. George's Ward in the city corporation, and at a meeting of his supporters last week he gave an account of his stewardship in the past, specially as regarded the health of the city. The death-rate has been reduced 3 in 1,000 in the past five years, he said, thanks chiefly to the efforts of the Public Health Committee. The meat and milk supply had been greatly improved, and the terrible epidemics which had swept over the city in past years were not, he thought, likely to be seen again.

Dr. J. D. Williamson has been returned unopposed to the corporation, and has refused the request of a number of his friends and neighbours to contest East Belfast with the late member, Mr. Wolff.

In South Belfast the two candidates, Mr. Sloan and Lord Arthur Hill, are both Orangemen and Protectionists, and, broadly viewed, there is little to choose between them, so some of the medical men in the division are taking the opportunity of pressing the importance of satisfactory answers to the questions put to all candidates by the local division of the British Medical Association, dealing with such matters as the reform of the General Medical Council, the Poor-law Service, Vaccination Laws, &c.

LETTERS TO THE EDITOR.

THE PROSPECTS OF MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When the immense amount of harm done by illegitimate practice is considered, the desire of the reformer naturally is to seek legislation to make such practice impossible. The same reflection occurs, too, with regard to quack medicines. Unfortunately, it is quite impossible to expect, with a reasonable degree of confidence that any House of Commons within the next few years is likely to pass any provisions of the kind."

It seems to me impossible that anyone with adequate knowledge of the history of medical legislation during the past fifty years can dispute the above statement, which I quote from your editorial "Notes" of January 10th. If this is the case, how can we account for the fact that the British Medical Association and the British Dental Association are apparently proceeding under the assumption that their Bill will be taken up and presented to Parliament without much delay? Do they expect the Bill will be adopted by the Government; do they believe that any Member of Parliament has the power to introduce and carry such a measure unsupported by the Cabinet? Not five per cent. of the members of either House ever know anything about medical affairs, or appreciate the truth about quackery. Introduction of the Bill by a medical member would aggravate existing prejudice, and would confirm the opinion of those who look upon such legislation as always devised solely for the advantage of the profession. The case against quackery needs to be stated fully and publicly. It is an enormously strong case. The medical quack, and the concoctor and the vendor of fraudulent quack medicines rank with the worst class of malefactors parasitic upon modern society. Their cruelty, their cowardice, their cynicism,

exceed by far that of the City shark, who merely robs his victims of their money. Many of them are fully aware that their trade is really murderous; that suffering wretches, who might be cured, or have their lives prolonged by medical science, are doomed to death through reliance upon worthless panaceas. Quackery and the trade in quack medicines inflict an enormous amount of injury upon the public, and especially upon the weak and suffering, who have more claim upon the guardianship of the State. Quackery manufactures disease, and converts simple maladies into chronic or incurable diseases. These facts are capable of demonstration, whilst it is doubtful whether, from the sordid point of view, the abolition of quackery would not cause loss rather than gain to legitimate practitioners, owing to the diminution in the number of invalids which the change would in time surely bring about. To bring the whole story fully and effectively into public view seems to me the essential step preliminary to legislation; and the only practical way to accomplish this lies through the medium of a Royal Commission. Such a Commission, as I have already pointed out in the *British Medical Journal* and in your columns, would have power to call witnesses, to examine them on oath, and to guard them against penalties for statements alleged to be libellous. Commissions on questions of much less importance have been appointed within late years, and the profession acting together ought to be able in time to gain this comparatively simple point. That efforts beyond this at the present time will represent an almost complete waste of force I am, for one, convinced; that my conviction is based upon sufficient experience to warrant me at least in having a strong opinion of my own I have, I trust, made plain to your readers in various letters.

I am, Sir, yours truly,

HENRY SEWILL.

January 10th, 1906.

DISCIPLINARY SINGING AND HEART DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your last issue, Dr. G. W. F. MacNaughton refers to a case in which he believes the enlargement of the heart to be due to "early disciplinary singing," on the grounds that "the rules of voice production and their frequent practice at an early age of life, when the organs are sensitive and growing, imply great nervous and physical strain."

It is in no spirit of contradiction that I venture to point out that Dr. MacNaughton probably refers to *brainless disciplined teaching*, as voice production from the earliest age with proper control of the respiratory mechanism is one of the best possible things, and any one trained to use correctly *the true motive power* in voice production, could not injure the heart and would be in the same position as children reared in the Colonies, where, from early age, they live mostly in the open air and shout and sing from morn till night. It is undoubtedly for this reason that Australia can supply so many fine singers and still retains many superior to those on this side of the world.

The description Dr. MacNaughton gives proves conclusively that the chest poise was and had been wrong for years. If at the beginning of the vocal studies the *true motive power* had been employed it would have been impossible for the vocal use to have entailed "the veins of the upper extremity being engorged; a left-sided appearance of the thorax, and a slight sulcus or shallow depression corresponding to the attachment of the diaphragm in front." The heart could hardly be affected if proper use had been made of the respiratory process, as has been proved practically by the result of my treatment in children, not only patients sent by medical men, but the sons and daughters of these latter.

I am, Sir, yours truly,

F. MATTHIAS ALEXANDER.

109, Victoria Street, S.W., January 12th, 1906.

OBITUARY.

SURGEON-GENERAL SIR J. EDWARD, M.D., J.P.

WE regret to announce the death at Brighton of Sir Joseph Edward, retired Deputy-Surgeon-General of the Indian Army, at the age of 75. Born in Cumberland in 1831, he went to school at Carlisle, and after a year spent in the Medical School at Glasgow, entered Guy's Hospital. He graduated M.D. of St. Andrews, and took the qualifications M.R.C.S.Eng. and M.R.C.P. London. In 1853 he gained a commission in the East India Company's Medical Service, and joined the Bengal Army a year later. He served through the mutiny, and during the rest of his career in India, was promoted to many important posts, including those of Professor of Anatomy, Physiology, and Medicine, Principal of the Medical College, and Surgeon of the European Hospital. Among many administrative achievements he found time to help Miss May Carpenter in advancing the education of native women. In 1876, Sir Joseph left India in broken health, which did not improve sufficiently to permit him to return to that country. He retired in 1879 with the rank of Deputy-Surgeon-General, and settled at Brighton, where he took an active interest in local affairs, and was thrice elected Mayor of the Borough. He unsuccessfully contested Brighton in the Liberal interest in 1895, and in that year, on the recommendation of Mr. Gladstone, Queen Victoria conferred on him the dignity of knighthood. He was formerly proprietor of *Indian Annals of Medical Science*, and the author of many treatises and books relating to Indian and to general pathological subjects. His many-sided interests present an ideal picture of a strenuous and distinguished life devoted to the service of humanity.

HARRY CAMPBELL POPE, M.D., B.S.LOND., F.R.C.S.ENG.

WE regret to record the sudden death of Dr. H. Campbell Pope, on January 2nd, at his residence in the West of London. He was the only son of the late Edward Pope, M.R.C.S., of Tring, and was born there in 1849. He was educated at Haileybury College, and at the Liverpool School of Medicine, and later at University College, London, where he obtained the diplomas of M.R.C.S. and L.S.A. in 1871. He graduated M.B.Lond. (with honours) in 1873, B.S. in 1874, and M.D. in 1878. He also became F.R.C.S. in 1876. In 1876 he settled in practice at Shepherd's Bush, where he took an active part in the foundation of the West London Medico-Chirurgical Society, of which he was President, and also Editor of its *Proceedings* in the year 1885-6. His contribution "The Beginnings of Disease" formed his inaugural Presidential address to the Society in 1889. In 1894, he read an important memoir on diphtheria, its causes, diagnosis, symptoms, complications and treatment, and the precautions to be followed for its prevention, especially in times of epidemic prevalence. He also read papers on inguinal colotomy, diseases of the pancreas, and the feeding of infants in health and sickness. Death was due to heart failure at the early age of 56. He has left a widow and several children.

WILLIAM GRAHAM, M.D., R.U.I., J.P., MIDDLETON, CHESHIRE.

WE regret to announce the death, on January 4th, of Dr. Graham, of Middleton, at the age of 51. Dr. Graham was born in the North of Ireland, and in 1874 obtained the degree of M.D. of the R.U.I. at Dublin, and the M.Ch. in 1883. He also studied in Edinburgh and at Owens College, Manchester, obtaining the D.P.H. of Victoria University in 1890. Dr. Graham settled in Middleton, where he built up a successful practice. He published papers on "Smoke Abatement," "Pauperism in Relation to Public Health," and on "Small-pox," and was medical officer of health to the borough for nearly twenty-five years. Dr. Graham took a great interest in education, and was a keen Liberal. He leaves a widow and two children to mourn his loss.

NEW SURGICAL APPLIANCES.

AN IMPROVED ASEPTIC SYRINGE.

By WYATT WINGRAVE, M.D., Physician to the Central London Throat and Ear Hospital.

THE defect of most piston and other syringes which are filled through the nozzle is the great difficulty of keeping them "surgically" clean. This instrument, however, since its parts are made entirely of metal and readily separated, can be easily sterilised. Further, its makers have, at my suggestion, added a nozzle which; being detachable, not only enables the syringe to be filled without risk of contaminating its interior through an infected aperture, but also facilitates the cleaning of the nozzle itself, precautions of the utmost importance in aural treatment. This syringe is made by the Medical Supply Association, of 228, Gray's Inn Road, London, with nozzles of various sizes.

LABORATORY NOTES.

ANDOUARD'S BEEF POWDER.

ANDOUARD'S BEEF POWDER (E. J. Reid and Co., Dunedin House, Basinghall Avenue, London) is well known in France and has recently been introduced into this country. It is prepared from the finest selected beef by depriving it of its water and indigestible parts, and then reducing it to powder by Andouard's process. The appended analysis shows what an extremely valuable food we have in this preparation, particularly in respect of its nitrogenous constituents, from a food point of view. It is a grey powder with an agreeable taste and can be taken in hot water, milk, tea, &c., according to taste. Not only in the sick room will it be a welcome addition to preparations already existing, but also in tropical climates where it is necessary to carry food in as small a bulk as possible, for which purpose it is supplied in hermetically sealed 60 gramme boxes. The following are the analytical data obtained by us from a sample of the Beef Powder:—

- Moisture, 6.18 per cent.
- Mineral matter, 4.14 per cent.
- Nitrogenous matter, 81.53 per cent.
- Fat, 8.15 per cent.

London Hospital Saturday Fund.

THAT most excellent institution, the Hospital Saturday Fund of London, has this year beat all previous records in the amount of its collections. In their report they note the growing interdependence of the three great Metropolitan Funds. The proposed amalgamation of throat and of orthopædic hospitals is given as an instance. Another point touched upon is the ever-green subject of hospital abuse, which the Fund considered over-rated, and we look in vain for any practical policy towards investigation or remedy. The proposal of the Hospital Central Board is mentioned with approval, and it is suggested that the Funds might form the basis of such a body. Lastly, the Saturday Fund justly congratulate themselves on their step in the establishment of sanatoria for workers suffering from tuberculosis.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

A QUARTERLY Meeting of the Council was held at the College on Thursday last, the 11th inst. Mr. John Tweedy, President, in the Chair. Mr. Bruce Clarke, F.R.C.S., was admitted a Member of the Court of Examiners. A Diploma of Membership was issued to William Arthur Bruce Young, of Bolton Infirmary, and a Diploma of the Licence in Dental Surgery was issued to Charles Magee Craig, of Belfast. Upon the recommendation of the Court of Examiners it was resolved that the list of Universities, whose Graduates in Medicine and Surgery may present themselves for examination for the Fellowship, without first becoming Members of the College, under the conditions of paragraph II., Section IV., of the Regulations for the Fellowship, be amended by the substitution of "Victoria University of Manchester" for "Victoria University," and by the addition of the Universities of Liverpool, Leeds, and Sheffield. Mr. G. H. Makins, C.B. was elected a member of the Board of Examiners in Dental Surgery (Surgical Section). Mr. Henry T. Butlin, Vice-President, was appointed Hunterian Orator for the year 1907. Mr. A. W. Mayo Robson, F.R.C.S., was appointed to represent the College at the Fifteenth International Medical Congress to be held at Lisbon next April. The following are the arrangements for the Annual Course of Lectures to be delivered at the College.

Hunterian Lectures.—Professor C. G. Seligmann, F.Z.S., "The Physical Anthropology and Ethnology of British New Guinea," February 12th, 14th, and 16th. Professor H. J. Paterson, "Gastric Surgery," February 19th, 21st, and 23rd. Professor Arthur H. Cheate, "Some Points in the Surgical Anatomy of the Temporal Bone from Birth to Adult Life," February 26, 28th, and March 2nd. Professor Warrington Haward, "Phlebitis and Thrombosis," March 5th, 7th, and 9th.

Erasmus Wilson Lectures.—Mr. James Sherren, F.R.C.S., "The Distribution and Recovery of Peripheral Nerves Studied from Instances of Division in Man," March 12th, 14th, and 16th.

Arvis and Gale Lectures.—Professor J. H. Watson, F.R.C.S., "The Viscosity of the Blood," March 19th and 21st, and Mr. Sydney W. Curl, M.R.C.S., "The Arterial Pulse; its Physiology and Pathology," March 23rd.

Richmond Asylum, Dublin, and the Local Government Board.

IN the King's Bench Division last week, counsel applied on behalf of the Local Government Board for Ireland for an order of mandamus compelling the Joint Committee of Management and the Resident Medical Superintendent (Dr. Conolly Norman) of the Richmond District Lunatic Asylum to keep their abstracts of accounts and prepare their half-yearly statements in accordance with the provisions of Article 110 of the Public Bodies Order, 1904, for a similar order directed to the County Councils of the County of Dublin, the County of Wicklow, and the County of Louth, and the Council of the Borough of Dublin, representatives of which together form the Joint Committee of Management of the Asylum, requesting them to cause to be prepared the abstracts of the accounts of the Joint Committee and the medical superintendent's half-yearly statement in the manner prescribed by the Order mentioned; and also for a similar order directed to Dr. Conolly Norman, requesting him to prepare the half-yearly statements of the Committee in accordance with the form prescribed by the Board. It appears that recently the Board came to the conclusion that it would be better to codify and harmonise all various orders, and accordingly they passed the Public Bodies Order, 1904. Several of the public bodies throughout the country were strongly opposed to this new Order, but he was glad to say they had all practically come

into line now. Some, of them, however, still held out, and would not comply with this Order, and amongst them were some of the asylums in Ireland, including the Richmond Asylum, which had point blank refused to comply with it. The Court granted the applications, directing conditional orders to issue against the Committee of Management and Dr. Conolly Norman.

Society for Relief of Widows and Orphans of Medical Men.

AT a Quarterly Court of Directors of the above Society held on Wednesday last, Sir Thos. Smith, Bart, Vice-President in the Chair, sixteen members were present. One new member was elected and one resignation was accepted. The Secretary reported that he had paid the sum of £603 to the annuitants of the charity as a Christmas present. The sum of £1,376, was voted to be distributed as half-yearly grants among the 54 widows and 19 orphans in receipt of grants. Seven letters had been received during the past quarter, from widows asking for relief, but this had to be refused owing to the fact that their late husbands had not been members of the Society. Full particulars of the Society and Proposal forms for membership may be obtained from the Secretary at the offices of the Society. Membership is restricted to registered medical practitioners, who at the time of their election are living within a radius of twenty miles from Charing Cross.

Coroners and the Local Government Board.—Report of the Auditor, Mr. Cockerton.

Local Government Board, Whitehall,

January 11th, 1906.

SIR,—I have to inform you that I have carefully considered the objections of the British Medical Association and other ratepayers, to certain payments made by the London County Council to Mr. John Troutbeck, one of the coroners of the county of London.

These payments were made to the coroner to reimburse him for fees paid to Dr. Ludwig Freyberger in respect of *post-mortem* examinations performed by direction of the coroner.

The charges to which objection has been made have been classed under the following heads:—

(a) Cases in which the medical man in attendance on the deceased before his death gave evidence before the coroner, but was not directed to make any *post-mortem* examination.

(b) Cases in which the medical man in attendance on the deceased during lifetime was neither summoned as a witness, nor gave any evidence at all.

(c) Cases in which no medical man was engaged in attendance on the deceased either before, or at, or immediately after his death, and in which the coroner did not summon a medical practitioner in actual practice in or near the place where the death happened.

(d) Cases in which a medical man was requested to make a *post-mortem* examination, and to give evidence, but although the jury made no application under Sec. 21 of the Coroners' Act, 1887, Dr. Freyberger was engaged to assist at the *post-mortem* examination.

The arguments on behalf of the objectors, together with those in support of the payments by the London County Council, were heard by me on two separate occasions, and after reviewing the whole of the facts of the case, and carefully considering the contentions on each side, I have come to the conclusion that I am bound to allow the whole of the payments in question in the accounts of the London County Council, and I hereby decide and determine accordingly.

Whilst arriving at this decision, I desire to express my sympathy with those members of the medical profession who are affected by Mr. Troutbeck's general mode of procedure, and I propose to refer to the matter in the report which I shall make to the Council at the close of the audit.

If requested to do so by any party interested in the matter, I shall be, of course, quite ready to enter a statement in writing of the reasons for my decision in the proper book of account, in conformity with the requirements of the Public Health Act, 1875, which is made applicable by the Local Government Act, 1888.

I am, Sir, yours faithfully,
(Signed) T. BARCLAY-COCKERTON,
District Auditor.

Metropolitan Asylums Board.

AN ordinary meeting of the managers of the Metropolitan Asylum District was held on Saturday at the offices on the Embankment, Mr. A. C. Scovell, the chairman, presiding. Mr. T. Duncombe Mann, the clerk, reported that during the fortnight ended Thursday last, 813 patients had been admitted to the Board's fever hospitals, 55 had died in those institutions, and 863 had been discharged recovered, the total number remaining under treatment being 4,150, as compared with 4,255 a fortnight previously—a decrease of 105. Of that number, 3,335 were sufferers from scarlet fever, 734 from diphtheria, and 81 from enteric. There were no small-pox patients under treatment. The Ambulance Committee reported that their experience of motor-omnibuses had confirmed them in the opinion expressed in their report to the Board last February, as to the suitability of motor traction for the purposes of the Board's ambulance service. The patients were in the vehicles much shorter times, and, consequently, suffered far less fatigue than in horse-drawn vehicles, and as much more work could be performed in a day by motors than by horses, the committee believed that the general adoption of motor traction would result in considerable economy. They recommended the provision of a motor workshop at the south-western ambulance station, and the employment, as a tentative arrangement, of a foreman and storekeeper, who should be a thoroughly qualified motor mechanic and driver. The recommendations were adopted. The Children's Committee reported that the Local Government Board had assented to the continuance of the use for a further period of twelve months of part of High Wood School for the accommodation of feeble-minded persons, but stated that they were advised that the temporary accommodation thus afforded should as far as possible be restricted to females. With regard to the setting up of a working colony for the feeble-minded, the Board stated that they sympathized with the object which the managers had in view, but that as the whole question is under the consideration of a Royal Commission, it appeared to them that any extended scheme should be deferred until that Commission has reported. In the meantime, the Board suggested that the managers should make arrangements as far as possible for the accommodation of the class in question by the utilization of one or more of their existing establishments. On the recommendation of the committee it was resolved to apply to the Local Government Board for their sanction to the use of Bridge School as a working colony for male feeble-minded cases when it is no longer required for ringworm cases.

Dustbins and the Daily Collection of Refuse.

In the King's Bench Division on January 11th, the case of the "Mayor, &c., of Wandsworth, v. Baines," relating to a contest between an occupier in Putney and the borough council as to the removal of refuse, was heard. The respondent, Mr. Baines, who resides in a house about 40 ft. from the highway, refused to comply with the requirement of the appellants to have his removable sanitary dustbin placed on the kerbstone in order to facilitate a daily, instead of a weekly, removal, under a bye-law of the London County Council, of refuse. Thereupon the Council declined to remove the refuse, although Mr. Baines had served them with a notice to do so, and was willing to place the dustbin outside his house in a position which was conveniently accessible to the appellants' servants. The respondent, therefore, laid an information against

the borough council for refusing to comply with his notice, and the magistrate fined them 20s. and 25 guineas costs. Against this conviction the appellants appealed. The appeal was dismissed with costs.

Dividing Hungarian Twins by Operation.

It is announced that Professor Kukula, of Prague University, has performed the operation of separating the sisters Rosa and Josefa Blazek, who have grown up united like the celebrated Siamese twins. A minor operation was first submitted to by Rosa, with the result that, while her temperature increased by six degrees, that of her sister remained stationary. This led to the conclusion that the twins enjoyed independent constitutions, and—so the correspondents state—it was found on inquiry that a few years ago Rosa had had scarlet fever and typhoid without her sister suffering in health (!) The operation, which has thus made two individuals out of one, appears so far to have succeeded perfectly, as no vital organs were involved.

The Apothecaries Hall of Ireland.

At the Gresham Hotel on Saturday evening the Governor of the Apothecaries Hall—Col. Adye Curran, F.R.C.S.I.—presided at a dinner of the members of that body and their friends. After dinner, and the toast of "The King," the chairman proposed the "Royal Universities and Royal Colleges." The Provost of Trinity, responding, thanked the Governor for his references to the good feeling which had existed among Irish educational institutions. For some years there had been a decline in the number of Trinity's students until less than 1,000 names were on the roll, but this had now been increased to more than 1,100. Sir W. J. Smyly responded on behalf of the College of Physicians. Sir Arthur Chance, in responding for the College of Surgeons referred to the question of medical reform, and said he had been opposed to the "one portal" examining system, because he thought it would be destructive to the Irish examining bodies. Sir Christopher Nixon, in replying on behalf of the Royal University, said he reciprocated what had fallen from the Provost of Trinity College, and that the two great Universities were animated by one feeling in common—to work for the good of the country. He should protest against the observation of the President of the College of Surgeons, who said that the introduction of the "one portal" system would be destructive to the Universities and Royal Colleges of Ireland. Sir Charles Cameron, C.B., in proposing "The Apothecaries Hall," said it was the oldest medical incorporation in the British Empire. The Governor responded, and, after other toasts, the dinner came to an end.

The Forthcoming Lisbon Congress.

CONSIDERABLE progress has been made with the arrangements for the holding of the fifteenth International Congress of Medicine at Lisbon in Easter week. It is announced that the national committee of Great Britain and Ireland has taken every possible precaution to secure the comfort of British visitors. The well-known steamship *Ophir* is to leave Tilbury on April 12th, and to return by April 20th. Whilst the *Ophir* lies in the Tagus the authorities will allot it the berth given to the Royal yacht when the Queen and Princess Victoria visited Lisbon recently, and passengers will be able to make the vessel their home during the Congress, their cabins being reserved, and meals served at regular hours. In this way it is intended to avoid the discomfort and confusion that were conspicuous some years ago at Madrid.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London W.C., on the 29th ult. The chair was taken by Dr J. Brindley James, and there were also present Dr Walter Smith, Dr. F. J. Allan, Mr. Edward Bartlett, Dr. Fredk. S. Palmer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts presented showed that

the business of the Society was in a very sound condition. The claims during the summer and autumn have been so light that the heavy expenditure incurred in the spring of the year has been more than balanced, and the whole year's working will once more show a margin in favour of the Society in the sickness account. As, in addition, a large saving is effected in the management fund and the investments earned considerably more than the rate of interest assumed in the valuation, a large sum will be found added to the financial reserves of the Society at the end of the year. Prospects and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London.

Instruction in Military Surgery for Civilians.

The first lecture of the course on Army Medical Duties, to which we referred in our last issue, will be given by the Director-General on Saturday next, Jan. 20th, at 4 p.m., at the West London Hospital, Hammersmith. It will be on the Constitution of the Army, its Organisation, Government, and Staff; on the Constitution and General Scope of Duties of the Army Medical Service, and on its relation to other branches, its status, and powers of command. This course has no connection with any particular Hospital or College. Other of the lectures will also be given at the West London Hospital for the convenience of, and at the request of, the gentlemen (about 30 in number) who initiated the movement.

Society of Apothecaries.

A MEETING of the assistants of the Society of Apothecaries will be held on January 23rd, at 8 p.m., in the Court Room of the society's hall, Water Lane, Blackfriars, to discuss the advisability of forming an Association. Ladies and gentlemen holding the assistant's certificate are cordially invited. Those unable to attend, but in agreement with the suggested Association, should communicate their views to Mr. Albert Howell, Hackney Union Dispensary, Rosebery Place, Dalston, London.

Prize for Essay on Epilepsy.

AN important prize has been offered by the National Association for the Study of Epilepsy for the best essay dealing with the etiology of that disease. The value of the prize is \$300, and all competitive. All essays must be sent in to the examining committee by September 1st, 1906, and the award will be made in the following November. Physicians from any part of the world may compete for the prize. Full information may be obtained from the president of the association, Dr. W. P. Spratling, Superintendent of the Craig Colony for Epileptics, Sonyea, Livingston County, New York.

Fire at a London Hospital.

IN the midst of a heavy gale on the 3rd inst., and during the bustle of the dinner hour, a fire broke out at Adenbrooke's Hospital, South London. Shortly after 12 o'clock, flames were observed to be issuing from the roof of the main block adjoining the women's wing at about the spot where the progress of the disastrous fire of two years ago was arrested. The patients were promptly removed from the wards to the men's side of the building, and the firemen, who were quickly on the spot, attacked the flames with such energy that in two hours the fire was completely extinguished. Happily, no loss of life resulted from this alarming occurrence.

Medicine v. Religion.

At a meeting of the Glasgow College Conservatives the other evening, Dr. R. Cowan Lees related a pithy anecdote. A doctor in a remote part of Ireland had a large parish practice. Tickets for medical attendance were distributed by the parish priest. One class of ticket demanded the doctor's attendance on the patient, while the other provided for the patient visiting the doctor. For some reason the priest took umbrage at

the doctor and issued tickets to remote parts calling for attendance. When the medical man saw through the little game, he took to declaring the patients to be so ill as to necessitate a visit from the clergyman. The doctor by this means made things so lively for the priest that a compromise was speedily brought about.

A Case for Public Warning.

OUR contemporary, *Truth*, calls attention to a new firm of American quacks, under the title of the "Theo. Noel Co., Ltd." It announces that a "master remedy," called "Vita-Ore," at four-and-sixpence a package, sufficient for a month's treatment or more, will be sent to every reader of the advertisement, on the condition that he sends the 4s. 6d. at the end of the month if he finds himself better; otherwise he is to pay nothing. An individual who applied for a bottle of the stuff the other day was naturally surprised when he received the following answer:—

"DEAR SIR,—We do not care to send trial packets to men suffering from the class of complaints to which you refer. We have abundant evidence that Vita-Ore is remarkably well adapted to the cure of such cases, but we also know that men suffering thus are very often utterly lacking in the spirit of fair play and honesty. We have therefore decided not to risk the loss of more money over such like. You may be an exception to the rule, and perfectly honourable, but we do not intend to take any risks in the matter." This refusal to fulfil a proffered contract surely deserves the notice of the Public Prosecutor. Under the new regime at the Home Office, the medical profession and the public may possibly hope for some protection from brazen and fraudulent quackery.

Conjoint Examinations in Ireland.

CANDIDATES have passed the third professional examination as undernoted:—C. J. B. Dunlop, G. A. Francis, M. J. Glancy, D. J. Hanafin, A. Hipwell, W. E. Hitchins, J. Holmes, P. Holmes, W. S. Moorhead, A. A. Murphy, J. McGreal, H. V. McKeogh, M. H. O'Sullivan, E. P. Punch, D. P. Walsh.

WE learn that the Cork branch of the Irish Medical Association has decided to support the candidature of Dr. Leonard Kidd for the post of Direct Representative for Ireland on the General Medical Council.

MR. HV. HUTCHINSON, F.R.C.S., surgeon to the London and India Docks Company, has been appointed surgeon to the Millwall Docks.

MR. CHARLES J. SYMONDS, F.R.C.S., President of the Laryngological Society of London, was, at the annual general meeting on Friday last, unanimously re-elected to the chair for the year ensuing.

REVIEWS OF BOOKS.

DONALD ON MIDWIFERY (a).

THE present edition of Dr. Donald's work has been revised, "in the light of the Midwives Act," and every care has been taken to make clear the conditions under which the midwife must call in a medical man. How far such directions are compatible with the value of the book to medical students the author does not explain. To our mind, they are incompatible. The fact that the work has reached a sixth edition shows that it is of value, but for ourselves we confess we are not favourably impressed by it. How much this is the fault of the style and general appearance of the book is, however, another matter. The illustrations are of the poorest quality, the type and paper is unpleasing, the system of leaded headings is bad, since the same type is used to commence sections and sub-sections, and the pages are

(a) "An Introduction to Midwifery: A Handbook for Medical Students and Midwives." By Archibald Donald, M.D., C.M., M.B.O.P., Gynaecological Surgeon to the Manchester Royal Infirmary, Surgeon to St. Mary's Hospital for Women and Children, Manchester. With numerous illustrations. Sixth Edition. London: Charles Griffin and Co., 1905. Pp. xii. and 192.

uncut. Why the author or his publishers should inflict uncut pages on a busy nurse or student is a mystery best known to whoever is responsible. We have, however, little doubt that it affects prejudicially the sale of the book.

THE PREVENTION OF SENILITY (a).

SIR JAMES CRICHTON-BROWNE'S writings remind us not a little of those of another medical knight of the same cognomen—Sir Thomas, to wit. Both love to stray a little off the beaten path of orthodox medical literature; both show a penchant for the curious and fanciful; and both have a weakness for rather pedantic terms of classical derivation. It is the fashion at the moment to raise Sir Thomas Browne to almost celestial heights, and there is therefore reason to hope that some reflected glory may fall on his namesake. Certainly Sir James's article on "Education and the Nervous System," published over twenty years ago in Cassell's Book of Health, deserves to rank as a classic in medical literature; it is more than a pity—especially at the present moment—that it should not be more easily accessible to school doctors and medical officers to Education authorities. The volume before us, containing two inaugural addresses delivered before Congresses last summer, cannot compare with that masterly performance either in substance or form, but nothing that the author writes is without a distinct interest of its own, and a critical mind can find much matter to sift when dealing with such subjects as the Prevention of Senility and the present Sanitary Outlook. Perhaps the most valuable part of the essay on the former subject is where it throws cold water on the wild hypotheses of Metchnikoff and Allchin, and the least valuable where it sets forth the author's equally unsubstantiated view that man's natural span of life is a hundred years. We can hardly admit that the author carries us much further forward in the quest of a golden old age, but the subject holds itself to fanciful treatment and gives many an occasion for *obiter dicta* such as he delights in. These we can cordially recommend to our readers. We are not sure that he is quite fair to Cicero, the Roman orator drew many types of old men in the *De Senectute*, but self-sacrifice was certainly a virtue he lauded highly. Nor are we at all prepared to admit that Shakespeare was suffering from bodily infirmity in 1611, and Sir James Crichton-Browne is certainly wrong about the poet's age at death. It gave us quite a "turn"—as the vernacular has it—to read that the *Lives of the Poets* was Johnson's greatest work; we almost heard the great lexicographer turn in his grave at the suggestion. Readers will find other thoughts of an equally suggestive and stimulating character in the rest of the little essay.

HYGIENE AND PUBLIC HEALTH. (b)

IN no department of medical knowledge, perhaps, does "the process of the suns" supersede current views and render them quasi-obsolete than in the branch of prevention. Discoveries in physical science and added familiarity with the natural history of pathogenic micro-organisms modify our conceptions of disease production and prevention, and oblige us every now and then to shift our points of view. We are therefore entitled to expect every succeeding edition of text-books and manuals of public health to be "revised, enlarged, and in a great part re-written," as in the present instance.

This is certainly an admirable compendium of public health data, principles and practice, and in the 600 pages, or thereabouts, the authors have managed to compress a working *precis* of the practical and legal aspects of the subject. The task of making

(a) "The Prevention of Senility, and a Sanitary Outlook." By Sir James Crichton-Browne, M.D., LL.D., F.R.S. London: Macmillan and Co., Ltd. 1905. 2s. 6d. net.

(b) "Hygiene and Public Health." By B. Arthur Whitelegg, C.B., M.D., B.Sc., F.R.C.P., D.P.H., Medical Officer of Health for Nottingham, and George Newman, M.D., D.P.H., F.R.S.E., Medical Officer of Health for Finsbury. London: Cassell and Co., Ltd. Price 7s. 6d.

such a synopsis is one of no small difficulty, but we have satisfied ourselves that brevity has not been purchased at the cost of accuracy or comprehensiveness.

It is worthy of note that the authors are very guarded in affirming the value of hospital isolation in such diseases as scarlet fever. While logically it may be assumed that the removal of patients from crowded dwellings "cannot have failed to limit infection," the fact remains that scarlet fever has not only not been stamped out, but, on the contrary, its prevalence has not been tangibly reduced. The conditions under which alone hospital isolation is desirable and likely to prove of benefit are numerous and onerous, and, it is to be feared, not generally fulfilled.

The volume will be found useful by students and medical officers of health for ready reference.

LITERARY NOTES.

IN "Medicine and the Public," Dr. Squire Sprigge's suggestive and informing new work, a gallant attempt has been made to explain to the intelligent layman the relationship of the medical man to public life and national well-being. The average man seems to consider that what he calls "medical etiquette" is an unknowable and entirely secret means for maintaining a kind of trade unionism, and he neither knows nor cares to know the means and measures taken for the education, safeguarding and advancement of those on whom at any moment he may depend for the protection and retention of life itself.

WE are of opinion that this unfortunate lack of sympathy between the profession and the public, while due in great measure to the apathy, ignorance and neglect of the latter, has been maintained and possibly aggravated by prejudice, superciliousness, and perhaps distrust on the part of the former. We should be glad to see the companion volume to that to which we have referred, which might be well entitled "The Public and Medicine."

"MEDICAL Electricity and Light Treatment," by Kate Neale, is a little handbook written by the sister-in-charge of the Actino-therapeutic department of Guy's Hospital for Nurses, who wish to gain some knowledge of the therapeutical applications of light and electricity by means of modern instruments and apparatus. It is pleasantly written, and is free from that pomposity and dogmatism which disfigure so many books written by nurses for nurses. The different forms of electrical apparatus are described, and their appropriate applications indicated. X-rays are dealt with in rather cavalier fashion, but Finsen Light gets two chapters to itself. We can recommend the book without hesitation for the purposes and for the readers it aims at.

THE Apsley Cookery Book is a tribute to the ingenuity of Mrs. John J. Webster and Mrs. F. W. Jessop, who inscribe themselves "two grateful patients" to the Originator (with a big O) of the uric-acid-free diet. The book is simply a cookery book for the diet formulated by Dr. Haig, and when one considers that meat, fish, peas, beans, and many other popular articles of food are rigorously excluded, one is agreeably surprised to find that it is possible to devise some two hundred recipes for *plats* made with substances reported to be incapable of importing the evil acid. We can certify that such of them as we have tried are palatable enough, and if the worst comes to the worst we begin to think life might still be worth living though restricted to a *regimen* drawn exclusively from this volume. Of course, all the alimentary substances described herein are old friends, but the merit of the book is to enable the cook to "go ahead" without reference to standard treatises or to what may and what may not be eaten by the elect. It is published by Messrs. J. and A. Churchill, price 3s. 6d.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for the MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

The Complications of Vesico-Vaginal Fistula.—An interesting case of vesico-vaginal fistula followed by hæmatometra and pyonephrosis is recorded by John Phillips (*Lancet*, Nov. 18th, 1905). The patient, æt. 29, was delivered of a still-born child after labour had been established four days, by means of "forceps or cephalotripsy," the date of the operation being Feb. 1896. Subsequently she suffered from a continual dribbling away of urine for which she was operated on in the May following. The condition of affairs met with on bimanual examination were remarkable, but a diagnosis was made of "vesico-vaginal fistula with complete atresia in the upper part of the vagina from union of the upper vesico-vaginal wall with the recto-vaginal wall, cutting off the cervix. The method of closing the fistula was that of flap-splitting or dedoublement, as the amount of tissue was very limited, and the result was satisfactory save for a small pinhole opening. Fourteen months later she was admitted suffering from severe pelvic pain and a soft phosphatic calculus was removed from the bladder. It was noted that the patient menstruated regularly through her bladder, without marked discomfort. In January, 1904, she returned to hospital and exploratory laparotomy was performed, which ended in the removal of the uterus, which proved to be filled with fluid of the same composition as that found in hæmatocolpos. The convalescence was easy. Six months later patient was again admitted to hospital and operated on by Mr. Carless for a tumour on right side, which was accounted for by renal calculi with a collection of pus. The result was very satisfactory. Dr. Phillips states that at the operation of hysterectomy the lower opening of cervix could not be found even by searching carefully with a probe, and suggests that a phosphatic secretion might have formed over the surface presenting into the bladder.

H.

Icterus Neonatorum.—BUSFIELD reports (*B.M.J.*, Jan. 6th, 1906) a series of cases of Icterus Neonatorum which he considers unique as regards both the number of deaths and the rapidity with which death ensued. The case recorded by Ashby and Wright in "Diseases of Infancy and Childhood," is, he considers, the only one which nearly corresponds. The mother had borne ten children, the first did not suffer from jaundice but died of bronchitis. The second child was jaundiced but recovered. The third, fourth, and fifth all became jaundiced and died. The sixth child on the second day became icteric and the colour deepened into almost a copper colour, and death occurred on the eighth day. The next two children also were affected severely, but recovered. The ninth child died from jaundice on the fourth day, likewise the tenth, which was markedly jaundiced six hours after birth. The children have all been born at full term between the mother's eighteenth and thirty-fourth year. No constitutional disease is manifested by either parent. A *post-mortem* examination was made in one instance and negatived any suspicion of syphilis, no morbid condition being found. The treatment consisted in a small dose of calomel followed by repeated doses of castor oil, together with soda and rhubarb mixture. As the woman has not reached the end of child-bearing years any suggestions for treatment are solicited.

H.

Fibroid Tumours of Uterus in Patients, æt. 40 years and over.—Bedford Fenwick (*British Gynecol. Journ.* Nov., 1905), when reviewing Four Years' Hospital Abdominal Surgery before the British Gynecological Society, enunciates the following principles in the treatment of fibroids of the uterus in women over 40 years of age. First, that a fibroid tumour of the uterus in a patient, æt. 40 and over, which fills the pelvis, in the great majority of cases exercises dangerous pressure on the rectum, bladder,

or ureter and should therefore be removed. Secondly, that in such a patient a fibroid tumour which extends centrally half way to the umbilicus and is nodular on the surface and hard should also be removed as soon as possible, because in the great majority of cases it will sooner or later undergo degenerative changes dangerous to the life of the patient. Thirdly, that where the patient suffers from frequent and prolonged losses, unchecked by rest or medicine, where the uterus is enlarged and nodular to level of pelvic brim, hysterectomy should be performed as the safest and most certain cure of the condition. By adopting the above rules, the patient escapes the dangers of (a) fatty degeneration of the muscle of the heart wall; (a cause of sudden death) from long-continued pressure of large abdominal tumour; (b) the increasing tendency after fifty years of age to the occurrence of degenerative changes in fibroid tumours of the uterus; (c) general septic infection of tumours fixed in the pelvis. Having lost the full blood supply they received during active menstrual life, these tumours almost invariably degenerate and often become infected from the rectum. Lastly, he maintains that an ordinary healthy fibroid is never painful, and where pain in such a growth occurs and persists in ninety-nine cases out of a hundred degeneration of the growth has commenced, and the sooner the patient is operated upon the safer it will be for her.

F.

Floating Kidney.—Longyear (*American Journal of Obstetrics*, Nov., 1905) submits as results of observations on the living subject and dissections on the cadaver, new views as to the causation of floating kidney. He describes a tendinous band formed by the gathering together of fine longitudinal fibres from the fibrous network forming the framework of the fatty capsule of the kidney, and extending down, attached to the posterior surface of the ascending colon till close to the junction of the ileum, and to a less extent on the posterior surface of descending colon on left side. This ligamentous union of kidney and bowel he claims as the most important factor in the etiology of nephroptosis. The full cæcum in its efforts to push its contents upwards is making traction downwards, which pulls the kidney with it by reason of this attachment, while on the other hand the descending colon makes its counter extension upward with its fixed point below. This will explain the greater relative frequency of the displacement of the right kidney over the left (15 to 1). The pulling down of the right kidney would also account for the symptoms of a "digestive" and "nervous" character, which so frequently accompany the displacement, because the fibrous band is adherent to the descending portion of the duodenum and pulling on it by a loaded cæcum causes sinking of the bowel. He advocates as an accompaniment of this contention that an operation, to be successful, must have for its aim the attachment of both kidney and bowel, and the one which meets these indications is the fixation of this "nephrocolic" ligament into the upper angle of an incision in the loin and the fastening of the redundant mesentery, if present, into the lower angle.

F.

Gastric Disorders of the Stomach.—Reder (*Amer. Journ. of Obstet.*, Nov. 1905.) cites cases of gastric disturbances—nausea, vomiting, epigastric pain, and symptoms of hysteria and neurasthenia, without any appreciable organic disorder of the stomach or any of the abdominal organs above the umbilical line, and wholly unrelieved by gastric medication, &c. A large number of these cases on pelvic examination revealed retro displacements of the uterus, lacerations of the cervix, or adnexal disease, and 75 per cent. recovered after complete removal of the disorder by operation. He traces the reflex symptoms through

the sympathetic nerves supplying the posterior wall of the uterus to the solar plexus, and through it to the plexus gastricus anterior of the stomach. The plexus gastricus anterior is formed by the left vagus, and in its cervical portion gives origin to the various meninges—irritation of this nerve causes vomiting. F.

Insanity Precipitated by Pelvic Disease in the Female.—Higgins (*Annals of Gynecology*) does not think that psychoses are caused by any local lesion, but that they may be precipitated by one, especially among women with a neurotic predisposition or "border-line cases." He thinks it is folly to hope for a cure from any operative measures upon those in whom the degenerative stigma are so well marked, as found in the large majority of insane patients. However, if they are not too greatly exhausted, humanity demands that they have every advantage given to all sick people regardless of their mental condition. The fact that there is greater percentage of pelvic disease amongst the insane than amongst women sound mentally should at least attract our attention. Hobbs, of London, Ontario, in 1,000 insane women found pelvic disease in 25 per cent., and these were treated in the same manner as if they had been sane. Forty-one cases had ovarian disease, in all of whom the ovary was removed. Of these, 20 recovered within a year after operation, and their average duration of insanity had been eighteen months. Ten improved mentally, whose average duration of insanity had been three years. In 68 cases of uterine displacement, mental recovery occurred in 48 per cent., and improvement in 20 per cent. In 60 cases of endometritis, 19 cases recovered averaging fifteen months' insanity. Hall reports examination of 126 insane women with well-marked pelvic disease in 92 per cent., and recovery of 25 per cent., and improvement in as many more. The cases most suitable for operation are the acute psychoses, next chronic melancholics, especially those whose histories show little predisposing taint. F.

Vesical Calculus in the Female.—Cumstan (*Journ. of Obstetrics and Gynecology*, Nov., 1905), in summing up the treatment of vesical calculus in the female, says as far as the medical part is concerned it consists in careful hygiene and alkaline medication, and can only be applied in cases of uric acid or oxalic acid calculi. The surgical treatment consists in urethral dilatation, vesico-vaginal or supra-pubic cystotomy, and lithotripsy. Each of these operations has its advantages and its indications. Dilatation is not possible in girls under 15 years, will not allow of extraction of calculi exceeding three centimetres in diameter, it cannot be employed in very elderly women without rupturing urethra, or in adults with incontinence of urine due to a weak sphincter, with these exceptions dilatation is an excellent operation. If, after dilatation, the stone is found too large to be removed intact, a few strokes of the lithotrite will be sufficient to break it up into fragments, which can be removed by the urethra with forceps. Colpocystotomy is to be resorted to in cases where the stone is large or extremely hard, or is developed round foreign bodies, also in cases of vesical infection, where it is necessary to drain the bladder. There exist, however, certain contraindications, the first of which is a narrow vagina, which will prevent necessary manœuvres, and then supra-pubic route should be adopted. Regarding the supra-pubic incision in women, it must be borne in mind that it is a more difficult operation than in the male; and that it is also difficult to distend female bladder with liquid or with air. On the other hand it allows one to make a much larger opening into the bladder than any other operation, and is specially suited to removal of large calculi in young girls, and the removal with the fingers of foreign bodies or large calculi which have become wedged into a diverticulum without injuring the mucosa; it also gives a perfect view of the interior of the bladder. Lithotripsy also presents more difficulty in the female than in the male owing to impossibility of filling the female bladder under the influence of narcosis, and being large and low there is no retro-prostatic fundus into which the fragments might drop

after crushing. But in the female it is not necessary to reduce the calculus into such small fragments as in the male, on account of the shortness of the urethra and its easy dilatation. Lithotripsy would seem to be the method of choice when the stone is friable and of medium size. It is followed by the spontaneous expulsion of fragments should any be left behind, and allows the patient to resume his ordinary life within a few days if preceding inflammatory complications of the bladder do not require drainage of the organ. F.

The Growth and Changes in Submucous Myomata.—While Gusserow only recognises myomata as submucous which have freed themselves from the substance of the uterus, and are pedunculated, Schröder also adds those myomata which have a broad connection with the uterine wall, and bulge the mucous membrane into a more or less large segment of a circle. Amann (*Monats. f. Geburtsh und Gynäkol.*, Jan., 1906) agrees with the latter, since the majority of the characteristic peculiarities of the submucous myomata, especially of the covering mucous membrane, are already to be found, while the greater part of the tumour itself is in close connection with the uterine wall. He reports a number of cases which illustrate the different and also the rare peculiarities of the submucous myomata. As regards the size of the tumours, authors in general agree that they very rarely reach a large size. Gebhard says, submucous myomata never reach a very large size, as, on account of their position, septic degeneration so easily occurs. Amann then describes a pedunculated submucous myoma which, lying in the vagina, raised the uterus higher than the umbilicus. "Adhesive implantations" of submucous myomata on the mucous membrane of the body or cervix of the uterus have already been reported, and Amann adds particulars of a case of vaginal implantations, a condition which seems to be very rare. There was no œdema to be found in many of the submucous myomata removed, but he has very frequently discovered it and considers that it, along with the growth of the tumour, conduces to the dilatation of the cervical canal. Just before and during menstruation, especially, they descend deeper—that is, they are plainly felt in the dilated internal os: later they recede ("polypes à apparition intermittente"). When septic degeneration of the myoma had occurred Amann very often found purulent tumours of the adnexæ, while generally with uterine infection one finds the pelvic connective tissue involved. This is to be explained by the path of the lymphatics. Even though the tumour has a long pedicle and thus is far from its original bed, still it sends its lymphatics to the fundus and adnexæ, and the parametrium frequently remains quite free. The prognosis is not so favourable when infection of the adnexæ has occurred. In such cases a rectal examination of the adnexæ is imperative, and after the removal of the septic polypi, observation during the following days will show whether the removal of the adnexæ with the uterus is also necessary. After the extirpation of myomatous uteri he has found severe inflammatory and purulent conditions of the adnexæ, even when the submucous parts of the tumours showed no distinct signs of destruction. The relations of the uterine ligaments and the neighbouring organs can be much altered by submucous myomata. In conclusion, he reports two cases in which submucous polypi were associated with carcinoma of the cervix. It is questionable whether it can be assumed that through the long-continued mechanical irritation of a myoma protruding from the cervix, through the contact of its usually much-ulcerated surface with the cervical canal, through the increased congestion of the uterus, &c., an opportunity may be given for the origin of carcinoma in a patient perhaps predisposed to it. G.

NOTE.—A summary will appear each week in the following sequence:—(1) "Recent Medical Literature." (2) "Recent Surgical Literature." (3) "Recent Gynecological and Obstetrical Literature." (4) "The Recent Literature of Anatomy, Physiology and Pathology."

NOTICES TO CORRESPONDENTS, &c.

SURGERY FOR ELECTION TIMES.

Conservative of course. With Liberal feeding for patient, Union by first intention, and a Radical cure!—A. D.

MR. G. C. CLARK.—We can trace no reference to the subject in our columns during the past three years, nor can we recall anything of the nature referred to in your letter that has appeared in our contemporaries.

DR. F. J. S.—We fear there is no valid hope for a change in the direction named, but will make enquiry.

A MEDICAL VICTIM TO A THEORY.

A telegram has reached this country from New York that a medical man, Dr. Sellwyn Russell by name, has just died of starvation; he believed that people ate too much, and that disease was avoidable by right living. He had entered upon a fasting experiment, to test, as he said, the influence of mind over matter, but carried his theory too far. He was in the habit of prescribing meagre diet as a cure for most ailments.

OMEGA.—The gonococcus is occasionally found in the blood. Gonorrhoeal arthritis often affects wrists and ankles as well as temporomaxillary and sterno-clavicular joints, and sometimes even the fingers. Recurrence is common, treatment often most unsatisfactory, and results to joints may be severe and permanent.

M. S. BRIERLY.—Write to the Registrar of the General Medical Council, Oxford Street, London, W. The *Medical Register* costs 5s., the *Medical Directory* 14s., or 11s. 6d. if ordered beforehand.

CONSULTANT OR GENERAL PRACTITIONER.

L. M. R. writes to ask our opinion in the following case:—He practises as a London specialist and some time ago sent a patient to a well-known Court physician for an opinion upon some medical point. Two years later he is surprised to find that the consultant in question has been attending that patient and his family on and off ever since for various maladies, some of them of a trivial nature. He asks if that is not "glorified" general practice, and if it is in accordance with accepted rules of etiquette.

[In our opinion the procedure is open to grave question. It certainly appears to violate the golden rule of "live and let live." Perhaps some of our readers may express an opinion.—ED.]

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 17th.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.)—8 p.m. Annual Address:—The President: The Life and Work of Bernard Renault.

SOCIETY OF ARTS (John Street, Adelphi, W.C.)—8 p.m. Dr. W. A. Alkin: The Scientific Aspects of Voice Development.

THURSDAY, JANUARY 18th.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.)—8 p.m. Dr. M. Dockrell: Bullous and Vesicular Eruptions (continued): V. Herpes; VI. Zoster; VII. Dermatitis Herpetiformis. (Chesterfield Lecture.)

FRIDAY, JANUARY 19th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.)—5.30 p.m. Cases and Specimens will be shown by Dr. C. W. Chapman, Dr. L. Guthrie, Dr. J. G. Emanuel, Dr. C. O. Hawthorne, Dr. R. Hutchison, Dr. E. Cantley, and Mr. N. B. Harman. Short Papers:—Dr. F. J. Poynnton: Jaundice.—Dr. P. Lewis: Erythema Multiforme.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.)—8.30 p.m. Paper:—Mr. W. Hunting: Glanders in the Horse and in Man.

MONDAY, JANUARY 22nd.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20 Hanover Square)—8 p.m. Annual Report. Papers: By Dr. A. G. Levy and Captain A. F. A. Howe. Illustrated with lantern slides.

THURSDAY, JANUARY 25th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 p.m. Card Specimens: Messrs. A. Stanford Morton and G. Coats, 8.30 p.m. Papers:—Dr. A. Maitland Ramsay: The Treatment of Detachment of the Retina. Mr. Simeon Snell: (a) A Case of Thrombosis of the Cavernous Sinus; (b) A Case of Acute Edema of the Eyelids. Dr. D. J. Wood: Case of Bilateral Hemianopsia.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.)—8.30 p.m. Clinical Meeting. The President (Dr. F. W. Cock) in the Chair.

Vacancies.

Seamen's Hospital Society.—Assistant Physician in charge of the Electrical Department at the Dreadnought Hospital, Greenwich. Applications to F. Michelli, Secretary, Seamen's Hospital Society. (See advt.)

Seamen's Hospital Society.—One Medical and one Surgical Registrar at the Dreadnought Hospital, Greenwich. Applications to F. Michelli, Secretary, Seamen's Hospital Society. (See advt.)

Seamen's Hospital Society.—Honorary Anaesthetists at the Dreadnought Hospital, Greenwich. Applications to F. Michelli, Secretary, Seamen's Hospital Society. (See advt.)

Seamen's Hospital Society.—Pathologist, with duties at the Dreadnought Hospital, Greenwich. Salary, £100 per annum. Applications to F. Michelli, Secretary, Greenwich. (See advt.)

City and County of Bristol.—Public Analyst. Salary, £450 per annum. Applications to Edmund J. Taylor, Town Clerk, Council House, Bristol.

Middlesex County Asylum, Napebury, near St. Albans, Herts.—Assistant Medical Officer. Salary, £160 per annum, with board, lodging, washing, and attendance. Applications immediately to the Medical Superintendent.

York Dispensary.—Resident Medical Officer. Salary, £120 a year, with board, lodging, and attendance. Applications immediately to W. Draper, Esq., De Grey House, York.

County Borough of West Ham.—Plastow and Dagenham Hospitals for Infectious Diseases.—Resident Assistant Medical Officer. Salary, £200 per annum, with rooms and board at Plastow Hospital. Applications to the Medical Superintendent, Plastow Hospital, London, E.

County Borough of Burnley.—Medical Officer of Health. Salary, £500 per annum. Applications to Peregrine Thomas, Town Clerk, Town Hall, Burnley.

Appointments.

BALL, WALTER, M.B., B.S.Lond., L.S.A., Resident Medical Officer and Registrar of the Cancer Wing of the Middlesex Hospital.

BUCKLEY, GEORGE GRANVILLE, M.B., Ch.B., D.P.H.Vict., Assistant Medical Officer of Health of the County Borough of Oldham.

FARNCOMBE, EDGAR LEONARD, M.B., B.Ch.Oxon., Certifying Surgeon under the Factory and Workshop Act for the District of Chudleigh (Devon).

HASTINGS, SOMERVILLE, M.B., B.S.Lond., F.R.C.S.Eng., Surgical Registrar to the Middlesex Hospital.

HOWELL, C. M. HINDS, M.B.Oxon., M.R.C.P., Medical Registrar and Lecturer to the Nurses at the National Hospital for the Paralyzed and Epileptic, Bloomsbury, W.C.

KEELING, G. S., M.B., B.C.Cantab., Clinical Assistant to the Chelsea Hospital for Women.

LEITCH, ARCHIBALD, M.B., Ch.B.Glasg., Assistant to the Director of the Cancer Research Laboratories of the Middlesex Hospital.

MILSOM, E. G. D., L.R.C.P.Lond., M.R.C.S.Eng., Assistant House Surgeon to the East Suffolk and Ipswich Hospital, Ipswich.

PRYCE, ETHEL J. M., M.B., Ch.B.Glasg., Clinical Assistant at the Evelina Hospital for Sick Children, S.E.

SNELL, E. H., M.D., B.Sc.Lond., Medical Officer to the Education Committee, Coventry.

STAMFORD, R. B., F.R.C.S.Edin., L.R.C.P.Lond., M.R.C.S.Eng., Certifying Surgeon under the Factory and Workshop Act for the Loughborough District of the County of Leicestershire.

Births.

ABERCROMBIE.—On Jan. 12th at 23, Upper Wimpole Street, London, the wife of John Abercrombie, M.D., of a daughter.

HOWARD.—On Jan. 12th, at Hamilton, Buckingham, the wife of Vincent Howard, M.R.C.S.Eng., L.R.C.P.Lond., of a son.

MANSELL.—On Jan. 11th, at "Crofton" West Hill, Hastings, the wife of H. R. Mansell, M.R.C.S., of a daughter.

TANNER.—On Jan. 12th, at Farnham, Surrey, the wife of Charles Edward Tanner, M.D., F.R.C.S., of a daughter.

DARGAN.—On Jan. 4th, at 45, Stephen's Green, East, the wife of William Dargan, M.D., of a daughter.

LYLE.—On Jan. 10th, at Eversley, Elmfield Road, Bromley, Kent, to Dr. and Mrs. H. Willoughby Lyle, a son.

RANSOME-WALLIS.—On Jan. 10th, at Carlton Road, Worksop, the wife of A. Ransome-Wallis, M.B., Ch.B., of a son.

Marriages.

FARNAN-MACKEN.—On Jan. 4th, at the Pro-Cathedral, Marlborough Street, by the Rev. Father Cullen, S.J., assisted by the Rev. Father Flavin, Adm., Robert Farnan, M.B., 5, Merrion Square, son of P. F. Farnan, Bolton Castle, Moore, Co. Kildare, to Laura, daughter of the late H. M. Macken and Mrs. Macken, 3, North Great George's Street, Dublin. No cards.

SMART-ORMROD.—On Jan. 6th, at East Coker, Somerset, by the Rev. C. Powell, Walter, youngest son of F. W. Smart, J.P., M.D., of Dublin, and grandson of the late Rev. Edward Nangle, of Achill, to Gladys Millicent, youngest daughter of the late James Cross Ormrod, of Wyresdale Park, Garstang, Lancashire.

Deaths.

BIDWELL.—On Jan. 10th, at 45, Church Road, Richmond, Surrey, Laura Jones Bidwell, second daughter of the late William Bidwell, Esq., M.D.

WELCH.—On Jan. 12th, at 61, Oxford Street, Southampton, Robert Welch, M.R.C.S., L.R.C.P., in his 78th year.

The Medical Press and Circular.

Published every Wednesday morning. Price 6d. Post free, 5jd.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 21s. per annum, post free, if paid in advance, or 22s. 6d. credit rate.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, 25 0s. 0d.; Half Page, 22 10s. 0d.; Quarter Page, 21 5s. 0d.; One-eighth, 12s. 6d.

Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion 6d. per line beyond.

No. 4.

NOTES AND COMMENTS.

The New Medical Members of Parliament

AMONG distinguished medical members of the new Parliament the names of Sir W. J. Collins and Sir George Robertson stand out prominently. Both are men of affairs, and both are well versed in scientific as well as in social and political matters. It is to be hoped, therefore, that their accession to the House of Commons will mark a new era in the representation of medical views and in the protection of medical interests. The Medical Acts stand in urgent need of reform, as everyone of our readers know, for the safeguarding of the public as much as of the profession.

Unqualified Practice. WHAT an incalculable amount of good, for instance, would be effected by a clause securing the effectual punishment of unqualified medical

practice! By a wave of the Parliamentary wand, the ill-gotten incomes of a host of quacks and charlatans would be diverted into their legitimate channels. It is easy to cry out against the "six-penny doctor," but he is nevertheless the direct product of our defective medical acts, and to some extent of uncontrolled hospital competition. Quack practice, however, has invaded all classes of society, and there are "specialists" of all sorts and descriptions in London and elsewhere thriving on guinea fees. Well may we cry aloud for the elementary justice of a new Medical Act!

Personation Case.

DURING the week an example was furnished in the Law Courts of the ease with which a clever knave may personate a medical man. A certain notorious rogue was prosecuted for fraud in connection with motor-cars. He had masqueraded under a number of titles and aliases, amongst them he had assumed the name of a "Dr. Forbes," and had taken charge of practices in various parts of the country in the guise of a qualified practitioner. Beyond a brief attendance at a London hospital, he had no medical standing. His fraudulent assumption of a medical title and of a medical man's personality, therefore, was divulged only as an accidental side issue in the course of a criminal prosecution.

The General Medical Council.

THE fact is, that the General Medical Council is practically powerless to prevent personation. In other words, the *Register* which is the chief end and aim of their exist-

ence is deprived of its main value by its loose and unbusinesslike conception. The lawyers who are alive to everything concerning their own material interests, insist upon yearly registration. Why should not the General Medical Council adopt so simple a safeguard? Not only would it enable them to identify names and addresses every year, but it would also bring them ample funds for administrative purposes. Although medicine is not a rich profession, yet its members would gladly pay a yearly registration fee as an insurance against personation. Here is a chance for one of our new medical M.P.'s to render himself immortal.

Hospitals that Refuse Acute Cases.

CLEARLY, our medical charities were founded with the view of affording succour to any poor person requiring medical or surgical aid. That view, however, is by no means always recognised by resident medical officers and hospital authorities. Last week an old woman was brought to our largest London hospital suffering from a broken hip. She was sent away to a local Poor-law Infirmary, where she died shortly after admission. Such cases, as a rule, run a chronic course, but in this instance the patient was probably suffering from shock when brought in the first place to the public hospital. We are at a loss to comprehend the basis of a charity of this kind if it be not meant to shelter old folks after so serious an injury as a fractured hip.

The Direct Representative for Ireland on the General Medical Council.

DR. LEONARD KIDD, one of the candidates for the post of Direct Representative for Ireland on the General Medical Council, has issued during the past week a further address to the medical profession of Ireland. In its course he promises to publish some correspondence which has taken place between him and Dr. Laffan, another provincial candidate, with regard to a preliminary poll with the object of selecting a single provincial candidate. This correspondence we publish in to-day's issue. Although with regard to the coming election, we as a journal, have assumed a completely impartial attitude towards the different candidates, we confess that Dr. Laffan's own letters have not disposed us to regard his candidature favourably. Under the circumstances, therefore, we cannot regret to learn that January 18th was the last day for receiving the names of candidates, and that Dr. Laffan's has not been found among them.

LEADING ARTICLE.

PUBLIC INSTRUCTION IN MEDICINE.

WHEN the amalgamation of the various medical societies becomes, as there is a fair prospect of its becoming, *un fait accompli*, all who are interested in the science and practice of medicine will hope that a strong, cohesive, and dignified body will come into being. Whether the title taken to designate it be the Royal Academy of Medicine or the Royal Society of Medicine or some other alternative, it is desirable that a style shall be adopted which will convey to the public that the body is one of authority and prestige, and it is no less desirable that its constitution shall be framed on as democratic a basis as possible. In this way will it be possible for the best thought in the profession to give itself expression alike in the choice of its officers, in the arrangement of its work, and in its influence with the public. If it is intended that the vested interests of the various individual societies which enter into its composition shall be maintained and perpetuated, then far better would it be that things should remain as they are; but if the societies are prepared totally to sink their identity for the sake of the common good and to work loyally together for the construction of a homogeneous influential central body, then there is every reason to anticipate that the standing of the profession in the eyes of the public may be appreciably and distinctly raised. If the amalgamating societies wish for an awful example of what they ought *not* to aim at, we can only point to the Royal College of Physicians and Surgeons. These fine old bodies, which were designed to forward the interests of medicine and to purify its practice, have deliberately refused to march in the van of progress. Resting upon their original charters and ancient privileges, they have continued to convert themselves into mutual admiration societies which exist for the purpose of perpetuating their own interests—as against those of the body of the profession. They have in consequence lost control of the profession to the General Medical Council, organisation of the profession to the British Medical Association, and now, if the cards be played judiciously, the scientific leading of the profession to the forthcoming Society. It will remain with them to justify their continued existence in the face of these public demonstrations of want of confidence. It is not, however, of the shortcomings of the Royal Colleges that we wish so much to speak as of the opportunities of the new Society. We repeat that we hope that Society will be founded on a basis of membership with common rights and privileges, and that its policy and construction will be determined by the suffrages of members, and not by an irresponsible official hierarchy. If this be so, the Society will rapidly assert itself as the mouthpiece to the public of professional opinion on scientific subjects, and it may thus serve a purpose of the highest utility. People too long have been left to form their own ideas from the penny-a-liners of the journalistic

offices armed with old editions of Quain's Dictionary of Medicine, or other reference works which they are equally incapable of understanding. Now the day has long gone by for the public to be kept in ignorance of the medical questions of the day; the cheap press and the sensational writers have seen to that. Authentic information from respectable sources not being forthcoming, garbage of a contemptible description has been served up to satisfy the craving created, with the result that the most erroneous ideas are current on medicine, pathology, and professional ideals. That this should be so is as embarrassing to the doctor in his work as it is detrimental to the progress of medical science, and a system of public instruction more in accordance with the best medical opinion of the day would confer far-reaching benefits on both the givers and receivers. The importance of this duty has at last been recognised by the New York Academy of Medicine, and it has inaugurated a series of public lectures by specially-qualified men to enlighten people on the problems that medicine is grappling with and the ways in which the solutions are being sought. These lectures are highly popular, and cultured persons are listening with pleasure and interest to views totally at variance with the stuff they used to get from the newspapers. But though such a series of lectures would be important channels of information, it is possible for the principle of keeping the public in touch with medicine to be developed along other lines of promise and utility. Thus, for instance, the Academy, or Society, might have a standing committee to whom could be referred all questions of reported cures or promised remedies on which responsible people wished an expression of opinion, and such a Committee could further give voluntarily such pronouncements on burning topics as seemed to them called for by the circumstances of the time. Many and various other means might be taken to accomplish the same end, namely, to place the public in sympathy and not in antagonism with the profession, but if once the principle we are contending for were recognised the particular means might be suggested by opportunity. But it is important that some such work should be undertaken, and we commend it to the notice of the new body, only making this reservation—namely, that in putting itself in sympathy with the public it should not put itself out of sympathy with the profession.

The Pay of Austrian Doctors.

A GENERAL strike is said to be contemplated by the communal doctors of Vienna as a protest against being compelled to perform vaccination, attend the poor, and notify infectious diseases for their present inadequate remuneration. It appears they are paid about twopence for each vaccination case and a week's subsequent treatment, whilst they get nothing for the notification of infectious cases. The highest salary paid to this class of practitioner is less than £30 a year, yet the communes profess to be unable to increase the remuneration.

NOTES ON CURRENT TOPICS.

Speculative Actions and Medical Witnesses —An Important Legal Decision.

ON the 5th of the present month Judge Russell delivered in the Wandsworth County Court a judgment of the utmost significance and importance to the medical profession. It must have happened to every medical man who has been engaged for any length of time in general practice that he has been subpoenaed to give evidence in an action taken up by solicitors on behalf of men of straw. The result of a "speculative" action under such circumstances, even when successful, means, as a rule, that the medical men receive no payment whatever for the attendance at Court, with all its inevitable expense and inconvenience. Henceforth Judge Russell has put a weapon of the strongest and most deadly calibre in the hands of the medical witness. In the case decided by him, Dr. E. A. Miller of Putney, brought a public spirited action against a Mr. Appleton, solicitor of Lincoln's Inn Fields, who had taken up the speculative case of Wright v. The Metropolitan Asylums Board. The defendant Appleton maintained that Wright was answerable for Dr. Miller's fees, and that the latter should have claimed his expenses before giving evidence. Judge Russell decided on both points against the solicitor, and refused leave to appeal. The judgment reverses hitherto accepted rules. We trust it will be duly considered and widely applied by the Medical Defence Union, whose views upon the point involved would be of great interest to our readers.

The Income Tax and Professional Men.

Now that the Liberal Party has assumed the reins of power, it would be well for medical men to bring prominently before their Parliamentary representatives certain grievances with which it may be more easy for a Liberal Government to deal than it would have been for their predecessors. Among these is one from which not only medical men but all professional men, and, indeed, all the higher wage-earning classes, suffer. It is manifestly unfair that in the incidence of income-tax an income entirely due to personal labour should be taxed at the same rate as an income resulting from invested capital. The former represents the result of personal toil and of long years of equipment, while the latter demands on the part of the owner no personal exertion whatever. From the former it is necessary to make provision for a non-earning old age, and for wife and children in case the earning period be cut short by sickness or death. Again, much of a professional man's income is to be regarded, not as the reward of labour, but as the repayment of the capital sum paid for a prolonged and expensive education. It is a distinct injustice that such recoupment should be regarded as taxable; as well might the return of any other invested capital be regarded

as taxable income. It is, we understand, not unlikely that some revision of the income tax system will soon be taken in hand, and it rests with professional men as a class to make sure that their interests are not overlooked.

"Journeyman" or "Assistant."

A WORDY war has been waged during the past month or two between representatives of the Pharmaceutical Society and of the Apothecaries' Hall of Ireland as to the legal status of the certificate of "assistant," granted by the latter body. It appears that in the eyes of the pharmacists the "assistant" has no legal standing whatever, whereas the Apothecaries' Hall holds that as "assistant" is a modern term for "journeyman," all privileges and rights formerly pertaining to the "journeyman" now belong, as a matter of course, to the "assistant." Into the merits of the question we do not enter, as it is obviously one to be decided by lawyers, but some interesting points of history have emerged during the controversy. It is stated that it was not till towards the end of the eighteenth century that apothecaries in Ireland entered on medical practice. About that time there was complaint in Dublin of physicians charging too high fees, in consequence of which, and for the first time, apothecaries were allowed to practise physic where it was not convenient to pay a physician. It would seem, too, that in recent times the Pharmaceutical Society was called into existence by the refusal of the Hall to grant any certificate entitling the holder to dispense and sell medicines without also practising physic. It is interesting, that whereas in the eighteenth century an apprentice was bound for seven years before becoming a journeyman, the Pharmaceutical Society can now qualify an assistant in four years, and the Apothecaries' Hall can do so in three months.

Vaccination Expenses.

Now that the elections are practically over and the composition of the new House of Commons is determined, we may expect to see the faddist, who has been silent for the last few weeks for fear of imperilling the chances of his party, unmuzzled once more. Of the faddists with whom the House will be troubled, the anti-vaccinationists are not likely to be the least turbulent and talkative. What lines is it probable that the anti-vaccinationists will take? They are two. First, they will attempt to bring about the repeal of those parts of the '98 Act which bear any semblance to compulsion, and, secondly, they will try to reduce vaccination expenses, or, in other words, the fees paid to public vaccinators. With regard to the first, to attempt a repeal of the Act, or, rather, part of the Act, will, we are sure, be strongly resented on both sides of the house, and could not reasonably be suggested without further inquiry. As to vaccination expenses, a member of the Wandsworth Board of

Guardians has just carried a motion calling the attention of the Local Government Board to the present expenses of administering the Act, and urging that the Guardians should have "freedom of contract" to engage doctors who were prepared to vaccinate for smaller fees. As a matter of fact, after a long inquiry by a Departmental Committee the present scale of fees has lately been arrived at, and any attempt to depart from this will be ardently resisted by medical men.

Osteosculpture.

A CORRECT and intimate knowledge of the bones is the foundation of anatomy, and anything which helps to give the student that knowledge and to fix it in his memory may be accounted a great gain. In the *Medical Record* for December 30th, a paper by Dr. Gifford describes a method he has been working at for some years for teaching osteology by modelling. After various experiments he has come to the conclusion that plaster of Paris is the best medium with which to work, and this he uses in the following way. A block, roughly of the required size is taken, and on its various surfaces the outline of the different faces of the bone are drawn according to scale, diagrams for the purpose having been constructed previously. The superfluous portions of the plaster are cut off and the outline carefully trimmed to the proper shape. With but little trouble, if the proper scales are used, a model of the bone can be produced which varies within narrower limits than do the bones of various human subjects. The sculptured piece is then hardened in glue and subsequently dried. In this condition it can be drilled and mounted as though it were an actual bone, and, of course, the insertion of the muscles marked in colour. Dr. Gifford is evidently an enthusiast, and he has induced Professor Price to try teaching his class in anatomy on this principle. The idea seems a good one but the method is rather elaborate, and we should have thought plaster of Paris too hard a material to work with easily. But the principle of teaching osteology by a constructive method is on sound lines, and we fancy that if modelling clay were used a personal acquaintance with the bones, as well as a valuable training for the hands, might be acquired in a more permanent way than any yet in use.

The Falling Birth Rate.

THE decline in the birth-rate seems to possess an almost irresistible attraction for the medical statistician and philosopher, and Circe-like it makes its suitors fall enslaved by its charm. The latest wooers of this captivating maid are Dr. Newsholme of Brighton and Dr. Stevenson of the London Education Committee, who presented a study on the question to the Royal Statistical Society last month. The value of their paper lay chiefly in establishing by authoritative

figures those conclusions which other reasoners have arrived at chiefly by conjecture and deduction. The authors find that fertility is reduced as social comfort increases, and that while the reproductive activity in the higher grades of society is certainly less than in the lower, the same principle applies to the proletariat as it rises in well-being and prosperity. In England and Germany this influence had been much marked of late, but Ireland, though its lower classes are probably somewhat better off than formerly, forms an exception to the general rule in that its birth-rate had actually increased. Denial was given to the assertion that decrease in the birth-rate is caused by the stress of modern life, the authors holding that it showed a determination on the part of a people to secure greater comfort. They arrived at the usual pessimistic conclusions—namely, that the "gospel of comfort" was becoming the ethical ideal of the people and that this connoted a lower standard of moral outlook, a lower regard for the married state, and a lower moral, and perhaps also physical, level among those who adopted it. The counter-arguments to these gloomy vaticinations are well-known to our readers, and we have generally felt ourselves that a slight loss in population, if obligatory—of which we are by no means sure—is a small price to pay for the greater comfort and well-being of the population generally.

Distilled Water a "Drug."

THE responsibilities of qualified chemists are being brought home to them by various legal decisions as regards the purity of drugs supplied to customers. Last week an important addition to the recent series was made in a West-end London Police Court, where a chemist was fined ten shillings, with three guineas costs, for having sold dirty distilled water to the prejudice of the purchaser. The Home Office analyst proved that the water was swarming with micro-organisms. The vendor, in defence, said the water was in the same condition as supplied to him by a wholesale firm. Clearly, distilled water should be collected in sterilised vessels and hermetically sealed, or it must soon become infected. If a purchaser ask for distilled water it is clear that purity is requisite for some special purpose, or he would be content to use the ordinary public supply. Suppose distilled water had been obtained from the Marylebone chemist by a surgeon in order to make an eye lotion. Had the polluted water described in Court been instilled into an eye the results might have been disastrous to everyone concerned. The decision that distilled water is a drug appears to be sound from the point of common-sense no less than of law. If chemists are going to deal

with distilled water in the unscientific manner indicated in this case it will be safer for customers in future to boil and filter plain tap water.

Company Promoters and the Medical Profession.

DURING the past week members of the medical profession have been assailed with a profusion of pamphlets relating to the Leon Syndicate for taking up a gold-field concession in Nicaragua. The capital of the syndicate is £75,000, and the circulars and prospectus are couched in the glowing and enticing language usual to such documents. There is nothing to distinguish the Leon Syndicate from the long procession of gold mines that have been paraded for the benefit of the British public in general. However, as in this instance a particular appeal has been made to the medical profession to support this South American venture, we feel it our duty to utter a word of caution upon the subject. Should any of our readers think of investing money in the Leon or any other syndicate, let him first take the obvious precaution of asking his stockbroker and his banker what they know of the Syndicate, and whether they think the reputation of the promoters is such as to warrant a reasonable chance of ultimate success. Medical men, as a rule, are not given to Stock Exchange schemes, especially in gold mines, and we fancy they will not be swept in numbers into any financial net, however well baited.

Febris Electiona Generalisata.

Etiology.—Social worry, exposure to wet and cold, over-indulgence in alcohol, have all been mentioned as predisposing causes, but the principal exciting one seems to be a too liberal or too conservative habit of life.

Pathology.—No gross lesions have been found after death, but pre-existing arterial degeneration may contribute to a fatal result. The primary disease would seem to lie in some disturbance of the cerebral circulation, caused by reflex inhibition of the normal vaso-motor nervous control. This gives rise to various psychic phenomena, and the muscles of the larynx, tongue, lips, and face are thrown strongly into action.

Symptoms.—The first symptoms that manifest themselves are to be found in alterations of the patient's habits, especially in the direction of disinclination for his normal work. Sleep is apt to be broken, and as the disease gains hold insomnia may become complete. Later acute delirious mania or profound melancholia may set in. The eyes are usually widely opened, the lips move incessantly, and the patient babbles incoherently. He easily becomes irritable and quarrelsome, and special attendants may be needed to restrain him. One of the most troublesome developments of the malady is when it proceeds towards hilarity, the subject then often losing self-control entirely and giving way to loud, piercing, inarticulate cries.

Treatment.—Isolation is essential. A good nurse may do much to calm the patient, but the strait-

jacket should always be at hand. Newspapers and lime-light pictures often act like a charm. The diet should be light but nutritious, and forced feeding may be necessary. Alcohol should not be resorted to, but a generous allowance of wine after the crisis may do much to restore the patient's spirits if he be unduly dejected.

Prognosis.—The outlook is good if the patient be carefully nursed, but death occasionally takes place. The malady is apt to run in cycles, intervals of about five years being the rule. A voyage abroad may advantageously be recommended when it threatens to recur.

PERSONAL.

By the will of the late Mr. James Henry Ceely, F.R.C.S., of Fulham, late surgeon at H.M. Prison Aylesbury, senior surgeon of the Bucks General Infirmary, and Surgeon-in-Chief to the Bucks County Constabulary, £500 has been bequeathed to that worthy institution, the Royal Medical Benevolent College. The deceased left his son £39,218.

H.R.H THE PRINCE OF WALES has expressed his satisfaction with the work of the Indian Branch of St. John's Ambulance Association.

THE Lord Mayor early last week attended St. Thomas's Hospital and unveiled a portrait by Bacon, of Mr. J. Gadesden Wainwright, who has been a governor of the Institution for forty years and treasurer since 1890.

MR. JAMES WILCOCK, J.P., of Blackburn, chairman of the Refuge Assurance Company, has celebrated his sixtieth birthday by giving £3,500 to local charities, £1,000 being to endow a bed at the Blackburn and East Lancashire Infirmary respectively.

MR. JONATHAN HUTCHINSON will deliver an address to the Hunterian Society to-day, January 24th, dealing with reminiscences of that body. The Society invites the presence of all medical men.

SIR WILLIAM H. BENNETT, in recognition of his long services to St. George's Hospital, London, has been appointed consulting surgeon to that Institution.

APART from any question of politics, it must be a matter of general regret that the medical profession has lost the services of so distinguished a representative in the Commons as Sir Michael Foster, who has been ousted from the parliamentary representation of the University of London by Sir Philip Magnus, the Conservative candidate, by the narrow majority of twenty-four.

A MAN, when arrested at the house of Mr. P. D., Sasun, L.R.C.P.Ed., at Walthamstow, on Friday night, calmly remarked: "I meant to have taken his life; he has ruined mine." Meanwhile the medical man is in the hospital in a dangerous condition, and the accused is in prison pending trial.

DR. T. B. NAPIER has been elected M.P. for the Faversham Division of Kent.

DR. RUTHERFORD has been elected as the Parliamentary representative of Harrow.

THE keen interest taken in the science and art of photography by members of the profession is shown by the fact that Dr. J. Alford Scott, F.R.C.S.I. of Dublin, is this year president of the Photographic Society of Ireland, and Dr. S. W. Allworthy, M.A. F.C.S., of Belfast, president of the Ulster Photographic Society.

A CLINICAL LECTURE

ON

THE INDICATIONS FOR OPERATION IN APPENDICITIS.*

BY

R. CHARLES B. MAUNSELL, M.B., F.R.C.S.I.

Surgeon to Mercer's Hospital, Dublin.

GENTLEMEN,—If one were to lecture daily on some aspect of disease of the appendix, it is doubtful whether at the end of a week more than half would have been outlined, let alone adequately discussed. I have to-day chosen a topic which has been the subject of debate in all civilised countries during the past fifteen years. The literature is so extensive and so scattered through journals, reports and monographs that it would be hopeless to expect the present day overburdened student to form his opinions directly from it. On the other hand, if the opinions and experience of others are neglected it would take more years of careful clinical observation and pathological investigation than form the natural span of human life before any one of us could solve the problem.

Therefore it is incumbent upon a teacher to absorb the work of others, to assimilate that which appears good, put it to the test, and, when it has been adopted or become inextricably blended with and modified by his own methods, to bring it before you in simple language, never fearing the accusation of being dogmatic.

One of the commonest remarks we hear or read in discussions upon appendicitis, and indeed of many other diseases, is that no rules for treatment can be made but that each case must be considered on its merits. This is most excellent advice provided those who are likely to act upon it conform to the following description:—(1) They must have a fairly extensive knowledge of the medical and surgical literature of the abdomen; (2) they must be careful and constant clinical observers; (3) they must have had some years' experience of the conditions disclosed by operation or autopsy, when certain clinical symptoms or signs had been observed. My advice is to start practice with an easily remembered set of rules and let future reading or personal experience point out the exceptions to these rules or add some new one to the list.

My belief is that the things which we can definitely state are as yet few, but these few may save many lives. Recently I was discussing this subject with some surgical friends and their opinion was that the subject had been fully thrashed out and that the man who could bring forward anything original upon the treatment of appendicitis would indeed be clever. I do not deny that the subject has been thrashed, but it has never been winnowed. With regard to originality, it is well to remember that striving after it will be to the detriment of our patients, and that it will only come unexpectedly to those who are working honestly and steadfastly without undue thought of self-glorification. It is a simple matter for you to test the truth of some of these statements for yourselves. When you leave this hospital to-day, ask the first three physicians whom you meet the following questions: (1) Would you give an aperient and an enema in a case of appendicitis? (2) Would you give opium or morphine? (3) Would you associate yourself with a surgeon early in the case? Then spend an hour in the library glancing through the chapters on treatment in the latest monographs, where you will see advocated various views, from prophylactic appendicectomy in every infant to the old treatment of Graves and Stokes by repeated doses of opium. To-morrow you come to me and say whether what

you have discovered would dispel the natural uncertainty with which you are likely to approach your earlier cases in practice.

In this hospital our practice is that purgatives and enemata should be given to patients who have been constipated, provided they are seen within the first twelve hours from the onset of the illness, and provided they show no signs of so-called "fulminating appendicitis." The best purgative is calomel and the enema should not exceed two pints.

Our practice is never to give opium or morphine unless operation has been decided upon, as even in small quantities they modify the symptoms. *Patients who have sufficient pain to need morphine had better be subjected to operation.*

With regard to the more obviously surgical questions, we may dismiss prophylactic appendicectomy in the healthy individual as fantastic. If in any patient we have opened the lower abdomen for some other condition requiring operation, the consideration of the prophylactic measure cannot be so easily disposed of. It appears to me to be only fair to our patient under such circumstances to remove an appendix which is known to have caused previous trouble, or which is kinked, adherent, cystic, or which contains one or more concretions, provided that there is nothing in the original operation which would negative this extension of our work. In otherwise trivial and absolutely aseptic operations such as suspension of the uterus, &c., more especially if the operator intends to use silk for his buried sutures, the appendix had better be avoided unless very markedly abnormal, and in this event it will be wiser to put aside the silk and use catgut for any buried suture in connection with the extraperitoneal portion of the operation.

Why not remove a normal appendix? It is not that I believe in any important physiological function which this little organ discharges, but because I am opposed to meddling surgery, and also the appendix has recently proved of great surgical use in the treatment of certain intestinal diseases such as mucous colitis, dysentery, &c., by enabling surgeons to perform the simple operation of appendicostomy. You have all seen the old woman who is at present a patient in the female surgical wards, in whose case I thus utilised the appendix to fix and drain the cæcum, which had become twisted upon an abnormal mesentery giving rise to acute intestinal obstruction from volvulus of the cæcum and lower ileum. Some surgeons, chiefly of American nationality, have solved all problems by operating in every case as soon as a diagnosis has been made, or even a strong suspicion of appendicitis entertained. Others operate if they have seen the patient within twelve or perhaps twenty-four hours of the onset of symptoms, but consider it safer to wait and be guided by subsequent events if this time has been exceeded, as they consider that once the inflammation has become well established around the appendix it would be safer to wait for the walling off of the diseased area by adhesions, when they could more safely operate, or perhaps allow the inflammation to run its course without further interference.

Operation during an uncomplicated attack has been strenuously opposed by the majority of European surgeons. To this opposition I have hitherto given what little help I could, but of late the more I reason with myself or others the more I think that quite enough opposition, very naturally, comes from the

* This lecture was delivered in Mercer's Hospital on January 20th 1906. It was illustrated by numerous specimens and charts, reference to which has been deleted from this report by the lecturer.

patients without our standing in the way of a line of treatment which is undoubtedly logical. I do not follow the reasoning of those who would impose a time limit, as there can be no danger from a carefully performed operation except pus or gangrene be present, and few would care to deny that the presence of either of these would prove without doubt that the operation not only was imperative, but that it should have been undertaken at an earlier period.

Granted that there are reasonable grounds for a diagnosis of appendicitis, and that the patient and the patient's friends are sensible level-headed people, should we advise operation at any period during the acute stage? Before an answer could be given we must be granted proper environment, proper assistance and the various other requirements of a modern operation. Without these I unhesitatingly state that operation should only be thought of when dangerous complications have declared themselves. All the requirements being granted, the patient or the patient's friends, should be given the option of an operation, but on no account would I undertake to urge operative treatment in a simple case, as any individual patient has a good four to one chance of recovery without any complications and a further even chance that should even the worst complications arise they could be safely treated if recognised at a fairly early stage.

You can see that whilst I consider immediate removal the most perfect method of treatment, yet, although I might suggest it or perform it by request, I would never feel justified in urging it as a necessary procedure.

We must next consider the antithesis of this immediate or a chad operation, namely, the interval or a froid, so ably advocated by Treves. The principle of this procedure is to remove the appendix at some safe and convenient time, subsequent to one or more attacks of inflammation, so that the patient may be rid of a constant source of dread or danger.

Opinions differ both as to the interval which should elapse after the acute attack and as to the number of recurrences and the residual signs or symptoms which would warrant either advising or urging this procedure.

My practice is not to wait too long after acute symptoms have subsided, from one to three weeks is generally sufficient. By operating early, adhesions will be more readily separated, the patient will be saved two distinct periods of enforced idleness, and will, moreover, be far more likely to entertain the idea of operation while the anxieties of his late illness are still fresh in his memory.

In discussing the proposed operation, the patient will wish to know the probabilities of recurrence, if he trusts to Nature. It is practically impossible to give an answer in percentages or chances, as various compilers of statistics have estimated the probability at every percentage from five to a hundred per cent.

Until more definite information can be procured we must assume the responsibility of *advising* operation after a first attack, of *more strongly advising* it after two attacks, of *urging* it when the attacks have been frequent, *being even more insistent* when they have been of a short colicky nature, as such pains generally indicate some obstruction or concretions with ever pending danger of acute perforation. All appendices which remain as a source of chronic discomfort, or which can be palpated or located by complaint of pain on pressure should be removed. If a patient has passed a year or more without a recurrence before he consults you, it is better to advise against operation, unless he contemplates going abroad, where operation might be impossible, or unless it would obviously relieve his mind to get rid of a useless and, to him, a terrifying appendage. There can be no doubt that this interval operation has been of inestimable value in restoring health and saving life; but we must never forget that it is only a prophylactic measure against future trouble and that when we are in attendance upon an acute case we should not obstinately strive to postpone operation for a hypothetical safe interval, but that we must act promptly should even a suspicion

of danger arise. I have lost patients through looking too far ahead, thinking of the nice a froid little operation which I would do, whilst meanwhile some barely suspicious sign or symptom had suddenly grown to alarming proportions, and the subject of my thoughts was removed to a place where intervals are unknown.

Now let us briefly discuss the danger signs and symptoms which may help us when treating acute appendicitis by the expectant method. The most important questions and the most difficult to answer arise at our first visit. Is it an instance of acute gangrene or perforation of the appendix, or are the symptoms, although exaggerated, merely such as frequently usher in a severe though uncomplicated inflammation?

It is well known that an onset characterised by high temperature, frequent pulse, severe abdominal pain, vomiting, rigor, or even marked collapse, may mean nothing serious. We must make up our minds what the onset does mean in time to open the abdomen within the first six hours, or at the furthest within twelve hours, if our patient is to have a reasonable chance of life. If the illness is going to take a favourable course the collapse will soon pass off, and the aspect of the patient will conform to his acute, febrile condition. The pulse and temperature may both remain up, may both increase or may both decrease in a *fixed ratio*. The pain in the abdomen, which at first may have been situated at the umbilicus, or more diffusely with this point for a centre, will most likely decrease and become more defined over the right iliac fossa. Rigidity of the abdominal muscles, if it had been present will decrease, except over the affected area, and abdominal respiration will be present although very probably in a modified form. *The rigidity will at no time have been so complete as that which marks some abdominal catastrophe.* Vomiting may or may not continue. The chief unfavourable signs and symptoms are (1) A flat or slightly distended abdomen, which is absolutely rigid. (2) A rising pulse rate with a stationary or falling temperature, or a continuously frequent pulse, with a falling temperature. (3) A history that pain was at first located over the iliac region, and then suddenly became more diffuse. (4) Pain referred to any portion of the genito-urinary organs. Retention of urine is not of much importance, but pain on micturition is of immense importance. (5) Fulness and marked tenderness found in the pelvis on rectal or vaginal examination. Whilst examining the rectum or vagina it is well to test with the other hand the rigidity of the abdominal muscles, to learn whether they relax when the attention of the patient is withdrawn. Of course we must not hurt the patient meanwhile with the pelvic hand, or the abdominal muscles will reflexly contract. (6) A peculiar pallid, drawn and anxious appearance of the patient, or of even more importance a dull leaden appearance when viewed from some distance. I have mentioned this sign last as it depends altogether on the keenness of observation of the surgeon or physician in charge, not because I attach slight importance to it.

Later signs will be (1) Steady increase of the pulse rate with only moderate temperature. (2) The tongue becomes dry and brown, whilst the vomited material smells like fæces or assumes the characters of the so-called "black vomit." (3) Distension of the abdomen becomes more marked, sometimes with great diminution or disappearance of the rigidity. (4) Free fluid may possibly be demonstrated in the peritoneal cavity.

In fact the diagnosis is no longer in doubt and any treatment is simply undertaken as a forlorn hope.

In my opinion any one of the foregoing ten symptoms or signs would indicate operation to a prudent surgeon, any combination of two or more of them should absolutely demand it from him.

I have known patients at the onset of their illness to present a grouping of some of these signs and symptoms, including that of board-like rigidity, but without elevation of temperature. My experience is that all such patients should be operated

upon immediately, for although we may not always find that the appendix is at fault, yet we will undoubtedly find perforation or strangulation of some other abdominal organ, with consequent peritonitis.

Having tidied over the first twelve or twenty-four hours safely, we must next inquire what constitute later danger signals. I will again tabulate them so that we may be concise. (1) Increase of symptoms after the first forty-eight hours. (2) A steady although gradual or a sudden increase of the pulse rate. (3) Difficulty or pain on micturition. (4) Remittent or intermittent temperature. (5) Rapid diminution of pain and tenderness whilst the general aspect of the patient seems worse rather than improved. (6) Occurrence of rigor at any period subsequent to the onset. (7) Marked tenderness or swelling found on rectal examination. (8) Absence of distinct improvement by the fifth day. (9) Incomplete subsidence of symptoms, except perhaps slight tenderness and infiltration, during the second week. (10) Recrudescence of acute symptoms at any period. It would be impossible in this lecture to discuss the various conditions which arise in peculiar or neglected cases such as subhepatic, hepatic, or subphrenic abscess, &c., neither would it be possible or expedient at this period to even outline the principles of the various operations which most of you have seen performed in this hospital, from time to time, for the various complications which I have mentioned.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of the journal. The lecture in next week's will be by Professor Louis Renon, Physician to the *Hopital de la Pitie, Paris*, on "*Right-Sided Pleurisy in the Subjects of Heart Disease.*"

ORIGINAL PAPERS.

THE TREATMENT OF SPRAINS.

By PROFESSOR H. MORESTIN,

Chirurgien des Hopitaux de Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I desire to make a few remarks on that common accident called sprain and its appropriate treatment.

Sometimes we have the chance of examining the patient almost immediately after the accident, a particularly favourable circumstance to prevent any troublesome results. More frequently, however, the treatment cannot be commenced before the following day, or even two or three days later. The blood effused has had time to accumulate in the synovia or to filter into the cellular tissue, and already inflammatory reaction has commenced at the seat of the accident and in its neighbourhood.

The first thing to be done is to relieve the pain and prevent or arrest the progress of the sanguineous infiltration. Later on it will be necessary to ensure the evacuation of the effusion, render to the region its form and suppleness, and prevent all complication.

When the lesions have already existed for some time, complications, as stiffness, atrophy, and persistent pain, may be expected and will have to be treated. Consequently the prognosis will be benign or grave, according to the treatment having been begun early, or several days, or perhaps weeks after the accident.

Theoretically, all sprains may be treated alike, but in reality different regions require certain modifications. Formerly, a large place was given to certain applications in the treatment of sprains. Some procured relief by the cold they produced, but the effect did not last long and that treatment was abandoned.

Physical agents can, on the contrary, render great service. Cold and heat have been employed in turn, and in many cases should be still recommended. Immersion in hot or cold water is one of the easiest things for certain regions, such as the hands and feet. For an ordinary sprain of the ankle, Baudens advised that the foot should be left in cold water as long as the patient felt comfortable in it. It was thus that he kept the part in cold water for two or three days, and then applied a compressive bandage. Without, however, going to such extremes, the cold bath, if it could be kept up for several hours, would be beneficial.

A better treatment is *warm* water, which produces very marked relief and is more efficacious. It is by this treatment that I would recommend you to begin. In regions other than the hands and feet—to the knees or hips, for instance—the heat should be applied by hot-water bottles or poultices. This treatment, in any case, is only preliminary to the essential and curative treatment comprising *mechanical means*, which, by pressing on the tissues, removes the blood and lymph exudations and consecutive infiltrations from the region. These means are powerful, rapid, and so efficacious that they take the first place in the treatment of sprains. Of all the mechanical means, *compression* is the most ancient. Before the use of cotton-wool it was a rough method, painful, and even dangerous. With the well-lined apparatus compression becomes easy to support and gives very good results; it drives the blood out of the cellular tissue and prevents œdema. The only reproach that can be made to it is that it condemns the affected part to complete immobility. Now, prolonged immobility in traumatisms of the articulation is one of the greatest errors of surgery.

Employed exclusively, this apparatus is considered to-day insufficient; wherever massage and the elastic bandage can be used, they are certainly the best resources at our disposal. Applied in the interval of baths and séances of massage, the compression apparatus finds its utility. It effectually maintains the result of the massage and contributes its part to the absorption of the exudation. The *elastic bandage* is, however, in my opinion, the best means to obtain this absorption and does not absolutely confine the limb; the movements it allows, however limited, are sufficient to preserve the function of the articulation. In any case, the band is not continually applied; it has to be removed about twice a day for washing, otherwise the moisture under the band becomes foetid and irritates the skin. Care should be taken in applying the elastic band not to draw it too tightly so as to cause pain.

It is obvious that the above treatment cannot be employed for sprains of the hip or shoulder; but we have another treatment, however, which is applicable to every kind of sprain, and that is massage. Massage was for a long time ignored by the surgical profession, and it was only towards the middle of the last century that, thanks to the

efforts of Bonnet, Girard, Estradere, and others, its merits were recognised. To-day nobody wants to contest its good effects, and there is even some tendency to exaggerate them.

The manual treatment of sprain is very simple. Massage comprises a series of movements with a view to render supple the engorged tissues, expel the stagnant liquids, and particularly the blood, and also to stimulate the muscles, tendons, and ligaments as well as the functions of the skin.

The method consists in pressure, more or less localised and more or less prolonged, by the hand, the thumb, or the four fingers. The pressure should be gradual, and centripetal, and never painful. At the beginning it should be very light and superficial, and when the affected region is accustomed to the contact a little more strength may be applied. Let us take, for example, a sprain of the ankle. The accident is recent, the pain intense, but the swelling still moderate. Massage practised at this period gives almost marvellous results; the infiltration being limited, the extravasated blood is still liquid and its absorption easy.

After the foot has been bathed, the surgeon will p lacesome vaseline on his hand and on the region of the ankle and begin by superficial rubbing of the limb from below upwards, in front, on the sides and behind. The pressure is increased very gently, especially over the seat of the lesion. The thumb, the fingers, the palm of the hand are all brought into requisition during the séance, and in a short time the patient begins to feel the good effects of the treatment. The excruciating pain disappears and even limited movements can be made by the patient. At the end of fifteen or twenty minutes the foot has assumed its normal aspect, only a slight sensitiveness being felt at the immediate seat of the accident. Motion becomes possible in the articulation, and the patient is surprised that he can stand up and even walk with but very little inconvenience. In slight sprains the cure may, from this moment, be complete and definite.

The same method, always very efficacious, is less so, and, above all, less prompt in its action when it is only applied the next day or the following, as will be seen. I have not once mentioned immobility as treatment of sprain, for it has been, and rightly so, discarded as hurtful by modern surgeons.

Up to the present, I have only spoken of the commonest of all sprains, that of the foot; but the same treatment can be applied to the wrist and the elbow. The knee, on the other hand, requires a more complicated treatment, for here massage is almost counter-indicated.

A sprain of the knee presents this peculiarity—that effusion into the joint is frequently considerable, whilst that around the articulation is almost insignificant. If the lesion is recent, the hæmarthrosis should be evacuated without delay by an ordinary trocar, and compression made over the joint with cotton wool for forty-eight hours; after which an elastic band is applied. The patient keeps his bed for a week, but is allowed to move the joint freely. If the lesion is not recent, compression of the part with an elastic bandage is combined with faradisation or galvanisation of the triceps and massage of the thigh. Massage of the knee itself is of little use. In sprain of the hip and shoulder, massage is the only good treatment when the lesion is recent, later the results are much less satisfactory.

THE SLEEPING SICKNESS IN UGANDA.*

BY CAPT. E. D. W. GREIG, B.Sc., M.B.Ed.
Indian Medical Service.

SLEEPING sickness broke out in Uganda in 1900, the country having previously been immune from the disease, and since its first appearance there 100,000 persons had died from it. A Commission was appointed by the Colonial Office, and he had been sent from India to take part in the investigation. The two main results achieved by the Commission were the discovery that sleeping sickness was due to the trypanosoma gambiense, and that the disease was conveyed by the Tsetse fly. Sleeping sickness had been introduced into Uganda from the Congo State; up till recently there was little intercourse between the two regions, but in 1900 some of Emin Pasha's soldiers crossed from the Congo basin and settled on the shores of Victoria Nyanza, and there the disease arose, since when it had spread all around the shores of the lake, but had not extended far into the surrounding country. Taking up first the clinical features of the disease, infection with trypanosomes was followed by a long period during which few or no symptoms were manifest. The temperature curve was normal, and the only sign of infection was enlargement of the superficial lymphatic glands, particularly those of the posterior cervical region. This was known empirically to slave dealers, who were accustomed to reject any slaves showing glandular swellings in this region, as they were aware that the malady would develop in them. Sooner or later, however, the temperature begins to rise, and the characteristic symptoms of the sleeping sickness develop, and progress steadily to the invariably fatal termination. A characteristic feature of the temperature is that during the last three or four weeks it falls to sub-normal, the body tending to assume the temperature of the surrounding air. The discovery that enlargement of the posterior cervical glands is an early evidence of trypanosome infection was of great importance in checking the spread of the disease, because the patients, being then in comparatively good health, moved about from place to place, and gave rise to fresh centres. When the nervous system became involved, with the onset of the febrile stage, the pathognomic symptoms developed. There were the typical facies, the somnolence, slow speech, tremor of the tongue and limbs, ataxia, and eventually loss of the power of walking. Not infrequently a certain degree of mental excitement, even amounting in some cases to mania, might occur. In the terminal stage, to which alone the name of "sleeping sickness" should properly be applied, the patient became semi-comatose, and lay huddled up with his limbs flexed, a mere mass of skin and bone. During this period the temperature fell steadily, the evacuations were passed unnoticed, food was not taken, and sores due to jigger-bites developed. At this stage the patient, if left to the natives, was put outside to die. The trypanosomes were at first present in the blood only, and in comparatively small numbers. As signs of implication of the nervous system appeared, the parasite could be detected in the cerebro spinal fluid. The blood showed no anæmia; indeed the red corpuscles and hæmoglobin might be above the normal in amount. The small lymphocytes were increased; this lymphocytosis corresponding with the action of the lymphatic glands. In the cerebro-spinal fluid of the period before the parasite was present in it there were only a few mono-nuclear elements; after the trypanosome had appeared, the mono-nuclear cells became very abundant. The pathology of the disease, according to Mott's observations, was that there was an aggregation of mono-nuclear cells in the perivascular spaces of the brain. Microscopically the exudate consisted of small lymphocytes with a few larger mono-nuclears and plasma cells. Mott believed that the symptoms resulted from the anæmia of the brain which these exudations into the peri-

* Abstract of paper read before the Edinburgh Medico-Chirurgical Society, January 17th, 1906.

vascular spaces produced. Another characteristic *post mortem* change was the occurrence of very numerous petechial hæmorrhages into the mucous membrane of the stomach; these areas were digested by the gastric juice and black erosions or ulcers resulted. Passing to their experimental work, Dr. Greig gave an account of the method in which the operations were begun, and described the appearance of the trypanosome. It had previously been known to be pathogenic to animals, but Dutton was the first to show that it produced disease in man. It reproduced itself by longitudinal fission; the question of whether there was also a sexual phase was still under investigation. They had detected the trypanosome in every case of sleeping sickness, and it next became a question as to whether the parasite was found in other persons from the infected area. It was found that about 50 per cent. of these natives harboured trypanosomes; a number of these cases were followed up and a considerable proportion subsequently developed sleeping sickness. Control observations made on a great number of natives in non-infected areas failed in any single instance to demonstrate the presence of the parasite. Coming next to inoculation experiments, they had chiefly employed monkeys. After excluding the presence of trypanosomes, these animals were inoculated with blood or cerebro-spinal fluid from patients, and in the sequel developed the disease. In monkeys, as in men, the course was chronic, and the temperature curve as well as the nervous symptoms were approximately the same. On examination of the blood and cerebro-spinal fluid, the parasite was found. The next step of the commission was to ascertain exactly the distribution of the disease by making extensive inquiries in all districts of Uganda. They found that it was endemic only around the lakes Victoria and Albert Nyanza, and that while fatal imported cases had occurred in the intervening country, none of these had caused epidemics. There was, therefore, some peculiar factor around the lakes favouring the spread of the disease. The suggestion occurred that it might be carried by the Tsetse fly, and a series of observations in the distribution of this insect were made. It was found that Tsetse districts were those where dense underwood surrounded the lakes; when the character of the country changed the insect disappeared. Several varieties of Tsetse were known; one of these (*glossina palpalis*) was the host of the trypanosome. Where blood containing the parasite was sucked by the fly the trypanosomes multiplied in its stomach, with great rapidity. Several forms appeared, probably representing a sexual phase. The Tsetse did not reproduce itself by laying eggs, but deposited one larva which in about three weeks hatched out into a mature insect. The next step was to infect Tsetse flies from sleeping sickness patients, and with them to infect monkeys. Tsetse flies free from trypanosomes were collected; these were fed on the blood of sleeping sickness cases and then were allowed to bite monkeys at periods of 8, 24, and 48 hours after they had sucked blood containing the parasite. The monkeys so inoculated took the disease, but the observers had never succeeded in conveying it by this means when the Tsetse flies had been kept longer than 48 hours after getting blood containing the parasite. Treatment had not so far been very satisfactory. Arsenic given subcutaneously had certainly the effect of checking the increase of the trypanosomes, but the effect only lasted while the arsenic was being administered. Arsenic along with trypan-oth, as advised by Koch, gave better results. Dr. Greig concluded his paper by describing his journey northwards to determine the limits of the distribution of the Tsetse fly. Wild animals in many parts of this district harboured the parasite, but were immune to its effects. Wherever both wild animals and the Tsetse fly co-existed, there domestic animals did not live. The wild animals acted as reservoirs for the trypanosome; they were "salted" and it was not impossible that some of the natives of the district, though harbouring the parasites, had a similar immunity.

THE MATERNAL FUNCTION AND THE NATIONAL LIFE.*

By WILLIAM ALEXANDER, M.D.R.U.I.,

F.R.C.S.ENG.,

Lecturer on Clinical Medicine in the University of Liverpool.

THE importance of the mother's influence in the formation of the race has been recognised by historians, statesmen, society, and by scientists. The Spartan mother has become a by-word, the Roman matron conjures up in the mind a woman stately and noble both in mind and body, inclined rather to the sterner qualities of nobility and producing sons and daughters of the same firm, unbending strain. The British matron, a good Christian, loving, sensible woman, full of kindness and of good nature, stately withal and thoroughly healthy, a woman who for centuries has reared her young bull dogs and sea dogs in such a way that with a footing in these small islands in the western main they have colonised a large part of the broad earth and dominated the sea. The mothers are the makers and the sustainers of the nation, and motherhood is the grand career for women. Some cynic has said that the function of women is "to suckle fools and chronicle small beer." This is obviously parody in both particulars. Women re-create the race for each generation, and purify and sustain society. To woman alone is entrusted by Nature the entire welfare of the child during its prenatal conditions, and to her especially is entrusted the nourishment of the child during the first nine months of its postnatal existence. After the child is weaned, it is not so dependent on the mother. Husbands, sisters, nurses, corporations, can nurse the nine months' baby up to childhood with success and even with a solicitude and self-sacrifice that may emulate a mother's tender care. Before weaning no one and nothing can efficiently take a mother's place, and in the prenatal period the mother is absolutely indispensable, the human ovum not yet lending itself to the artificial influence of incubators, and so enabling women to evade altogether the pleasures and penalties attached to their sex. It is satisfactory that we may contemplate our decease before incubated men and women occupy these chairs. It follows therefore that a woman who would be a suitable mother requires a thoroughly normal, healthy condition of the body, so that she can afford suitable nourishment during the formation of the child. She requires an equable quiescent and stable condition of mind as well as of body during pregnancy, so that, neither nervous influence nor physical shock may partially or entirely dislocate the growing foetus from its somewhat precarious attachment to the maternal structures and bring about a deformity, an abortion or a miscarriage. We have still many mothers in this country who are filled with a sacred joy when they feel the indications of another life within their own, and who instinctively and lovingly take every care that the promised fruit of their womb may come forth in due time, a full fledged, perfectly healthy baby. But it seems to me, and this is the burden of my story, that a gradually increasing number of mothers are careless, not only of the prospects but even of the existence of the unborn child. Does a condition of pregnancy interfere with a proposed trip by sea, a series of social engagements, or the pleasures of a festive season? I have known instances where the production of abortion has been contemplated and proposed and even "accidentally" carried out as a solution of the difficulty, and the possible destruction of the foetus was entertained so lightly, that the mere suggestion of the word criminal in connection with the means employed—viz., a gallop on horseback, or a game at tennis was laughed at by the unnatural though refined mother. In such cases, premature labours and still-births may result long after the indiscretion

* Abstract of Presidential Valedictory Address delivered before the British Gynaecological Society, January 11th, 1906.

has been forgotten, or if remembered is not recognised as a cause.

I have tried to obtain statistics of the annual number of still-born children and of abortions, but neither are recognised by the Registrar-General and consequently not tabulated in the death registers. The premature births are, however, registered, and in 1902, 18,909 children died from the effects of premature birth, that is, from some defect in the antenatal development or nourishment of the child. The causes of death in still-born and premature children is exactly the same and due to some fault in their environment during the antenatal period. We can only guess at the number of still-born children. In the Liverpool Workhouse Lying-In wards amongst 2,829 children born, 225 were still-born, many of these having died some time before birth. If we take these numbers as a basis, knowing that 948,271 children are born annually in England and Wales we find that 88,752 of these are still-born. This is probably too high an estimate, as the mothers in a workhouse hospital are more frequently diseased and dissipated than those of the nation generally. On the other hand, some of them are strong, vigorous women who are better mothers physically than many in the higher classes of society. As to the numbers of miscarriages and abortions, we can only proceed as before from known figures to the unknown. For instance, in the year 1903, 152 women are reported by the Registrar-General to have died from abortions or miscarriages. The mortality of abortions is very small, certainly not more than half per cent., probably much less. A half per cent. mortality of abortions would give 30,400 abortions and miscarriages annually. We have, therefore, by adding together 88,752 still-born 18,909 premature births, and 30,400 miscarriages, a grand total of 138,061 children who are conceived but who die every year from causes affecting them in the antenatal period. We know that Nature is most lavish in her provision for the continuance of the race, and squanders material in her laboratories in an apparently reckless manner. The mother aborts often in spite of the greatest care to prevent it, nay, in consequence sometimes of too much care and anxiety to prevent such an event, and medical men of the greatest experience often fail to help the mother in such cases. We admit this, and while we may doubt the absolute reliability of the figures given above, which I ask you to remember are put forward only as rough estimates, it will be admitted from everyday experience that at the present time many children are conceived and develop to a certain extent, but perish through maternal carelessness or ignorance, or both; and that multitudes of half-made infants, if we may use the expression, are born to be a weakness to the nation owing to the same ignorance and carelessness.

It should be the business of self-governing communities like ours to see that every member is effective and performs his or her part in maintaining the life of the nation. The industrious and respectable members who support themselves and bring up their children to be strong, healthy, and useful members of the community ought to be protected. They will be overborne if they have also to support an increasing and indefinite number of illegitimate or homeless and unmothered children. It is true that mothers of illegitimate children are tabooed in society and are outcasts, but they continue to have illegitimate children year after year without check or restraint. Our industrial schools are full of them, and the rest are the results of improvident marriages. In a minority of cases, death and sickness or unpreventable misfortune leave the children of decent parents stranded in such a way that only such places will take them in. It would seem to be advisable, and will soon be absolutely necessary, to have what we ought to call a Marriage Board composed of the wisest and best and most honourable in each locality, before whom pairs desiring to enter into the state of matrimony would, as a necessary preliminary, appear and satisfy its members that provision had been made for contingencies during the first

few years of married life; that the man was healthy, of good character, in steady employment for a sufficient number of years, and likely to be a good husband, and that the woman was healthy and vigorous with no hereditary disease, who recognised the responsibilities she was taking upon her in entering into the married state, and that she possessed some knowledge of the nature of her responsibilities and of how to deal with them. A certificate from such a Marriage Board should be given, and a contract, signed and witnessed, should be handed to the clergyman before he performs the sacred rite.

The Marriage Board should, through lady visitors, inspectors, or nurses, keep in touch with the newly-married so as to help them by advice and sympathy where they seem to require it, and with substantial help should misfortune assail the pair during the time of the mother's pregnancy. A pregnant woman should be helped without questions by the purveyors of public charity. Should she be undeserving, the unborn child is always innocent and deserving. A single woman should only be allowed to have one illegitimate child without interference. She may have been deceived, being innocent and inexperienced in the ways of men, but the same excuse will not avail twice. After the second time she might be sent to an institution to be kept out of harm's way, and be required to work for her living and that of her children under supervision. The father, if known, should be taxed to the same extent as legitimate fathers are for the keep of his illegitimate child.

During the antenatal nine months the onus of supplying nourishment to the mother and child rests upon the husband. The mother has only to nourish herself generously, and Nature passes on its due share to the child. When the child is born Nature has provided an inexhaustible source of suitable diet for it well preserved and well protected from contamination in the mother's breast. This is the birthright of every child, a birthright that places it above risks resulting from the ignorance or selfishness of the mother.

The nursing of a child necessitates the giving up by the mother of many things that she has loved. Her diet must be taken with an eye to the child's welfare. She cannot leave the child for long, and her duties to society must be subordinated to her nursing duties. To fashionable people the nursing of children becomes an intolerable nuisance. The child is delegated to the nurse and the bottle, and many mothers bring up their children in this way with apparent success by the aid of science, more or less specious, and much expenditure of money on advertised infant foods.

However much doubt there may be about the number of children that die in a prenatal condition, there is no doubt about the numbers that die in the first year after birth, that is, during the nursing period, when the child should be still dependent on the mother. The mortality of the new-born during the first year is 133 per thousand for the most recent year an approximate total of 126,117. This includes the 18,909 deaths from premature labour, but does not include the 119,152 still-born and abortions that might be imagined to have died during the prenatal period. The total number of children who die while in the mother's care is 245,269 annually, or in round numbers a quarter of a million. Now, the loss of prenatal children does not call for any pity for the sufferings of the deceased. They were not conscious and could not realise what they failed to become. The number (18,909) of children prematurely born, however, died early with the usual pangs, modified no doubt by the imperfection of their constitutions. Indeed, I believe that the Creator has so arranged matters that helpless babies die off more easily and painlessly than older people, otherwise the thought of upwards of one hundred thousand who die annually before their first birthday would be more appalling than it is. Many, no doubt, die from disease, in spite of every effort on the part of their parents. But ignorance and imperfect diet, drink, neglect and thriftlessness carry off numbers that may be counted by

thousands. Let us hope the new Royal Poor-law Commission will take up the cause of these helpless children and thriftless vicious mothers, and see that the Poor-law hospitals are not used, as they are at present by depraved women, for their own convenience, but will so arrange that women who bring children into the world and fail to look after them, and who kill them by neglect, carelessness, or intemperance, will be liable to punishment, and that the child may be rescued from the mother and protected from its earliest infancy. The mother should be deprived in some effective way of the opportunity of having more children, as surely the nation does not wish the continuation and the gradual increase of such a race. Let us look for a moment at the extent of the mischief. Taking the statistics of the Liverpool Workhouse Hospital for a recent year, 1904: Out of 389 births in that year, 158 were single women who were delivered there of illegitimate children. Of these 106 were confined of their first child, 31 of their second child, 16 of their third, 13 of their fourth, 9 of their fifth, and we have known some cases of the half dozen. Let us think for a moment of the extent of illegitimate births in one of the workhouses of Liverpool only, and there are two others. In one year 158 mothers brought forth as many illegitimate children into the nation, both mothers and children being fostered and cared for during their confinement with all the grand results of science in a way that the mothers of even middle-class independent and hard-working people cannot command.

Here we have the source of the deterioration of the race, of the decadence of the nation, of the ever increasing floating population who prey on the effective citizens and weigh down the prosperity of the community. It may be said that the majority of these 158 babies die within the year, and that such deaths are a merciful dispensation of Providence. It would be well were it so. But I have followed up 304 such babies born in 1903, until a year after their birth, and find that only 88 died of various diseases. That is 216 every year live to pollute the population out of one city parish, and there are several hundreds of such parishes. Their death-rate is at present 280 per thousand, rather more than twice the average. Not a word can the authorities say to these women. The foremost aseptic conditions are prepared for their confinement in the wards of most of the workhouses, and hard working men and women in the country have to pay to support them and their children not only during the infancy of the latter, but as tramps and criminals into which they degenerate for the whole of their lives.

My conclusions are:—

1. That the prosperity of the nation depends on the "annual output" of healthy vigorous children, whose parents are independent and perform their legal duties to their offspring, nourishing them and bringing them up to be sturdy fellow citizens like themselves.

2. Members of the community who do not possess the brains, the vigour or the health to make a place for themselves in the land, who cannot in other words build a nest for their young, should not be allowed to marry. They themselves are so much dead weight in the country, swelling the ranks of the unemployed and the criminals, they propagate their kind readily and rapidly, and, owing to a sympathetic and generous Poor-law, safely, assisted by the many overlapping agencies that make it easy to evade the old Scriptural law, which saith: "He that will not work, neither shall he eat."

3. That the nation should insist on mothers nursing their children. It is, as was said before, the birthright of the child, and as soon as the child is born it is under the protection of the community who should insist upon its having its birthright where it is possible.

The Fellows of the British Gynæcological Society can, by their great influence and knowledge promote these objects, help to increase the vigour and force of the nation, and proportionately to diminish the human rubbish which is now being propagated at such a rate as to threaten to retard the onward march of humanity.

THE OUT-PATIENTS' ROOM.

WESTERN OPHTHALMIC HOSPITAL.

Lachrymal Gland Abscess.

UNDER the care of Mr. G. W. THOMPSON, M.B., F.R.C.S. The patient, a child *æt.* 6, was brought to the out-patient department with marked swelling of the eyelids, slight chemosis of the conjunctiva, and moderate proptosis, the eye being directed forwards, downwards, and slightly inwards; there was practically no movement outwards of the globe. On examination under an anæsthetic a slight fulness and hardness was detected in the outer angle of the upper cul-de-sac. After dividing the outer canthus a Græfe knife was pushed up and out into the region of the lachrymal gland, and a few drops of pus were evacuated. Hot fomentations were applied. The child was seen every day, and in two days the proptosis had entirely disappeared, and by the end of the week all swelling of the lids had gone and outward mobility of the globe was completely restored. Mr. Thompson said the interest of the case lay in the fact of proptosis. He thought that perhaps this could be explained by the inflammatory condition spreading backwards into the orbit; as a rule in cases of lachrymal abscess the swelling is quite obvious either on external palpation of the lid or when the patient is made to look downwards, and at the same time especially inwards, because the inflammatory condition spreads forwards. A characteristic symptom of lachrymal abscess is œdema of the ocular conjunctiva limited to a small area between the outer canthus and the outer border of the cornea.

Rounded swelling below the lachrymal sac, lying on nasal bone and superior maxillary.

The patient, a young man *æt.* about 20, was supposed to have symptoms of a lachrymal sac abscess. He had a swelling about the size of a small marble just below the sac region. This was opened and some yellowish red pus escaped, this being suggestive of a broken-down gumma. The wound was sewn up and a small drain was left. On the next visit of the patient, five days afterwards, the wound was re-opened, and a probe, after a sinuous course, found its way into a bad tooth; the latter was removed, and the abscess then promptly healed. Mr. Thompson remarked on the peculiarity of the case; it might have been a gumma or a suppurating sebaceous cyst. The disease in the tooth had evidently been the primary cause, but this had not been suspected by him when he first opened the abscess, as he had never previously seen such a condition.

OPERATING THEATRES.

NORTH WEST LONDON HOSPITAL.

FRONTAL SINUS DISEASE.—MR. MAYO COLLIER operated on a man, *æt.* 27, who was suffering from pain and swelling in the right frontal region. The history of the case is as follows:—Six months ago the patient was affected with a severe nasal catarrh which was complicated after a few days with pain in the right frontal region. The pain was not sufficient to incapacitate him from work, nor was the temperature apparently increased, as he took his food and slept as usual. Between a fortnight and three weeks after this seizure he complained of tenderness over the right frontal region about an inch and a half above the inner angle of the right orbit. He sought local advice and was very properly treated for an abscess of the frontal sinus. Expert advice was subsequently desired, and the case was sent to the North-West London Hospital, under Mr. Mayo Collier. The specialist who had seen the case had made an incision over the swelling, and had come upon dead bone and a considerable quantity of pus. The case was admitted into the hospital about a month ago, and was seen within forty-eight

hours by Mr. Mayo Collier. On examination there was a wound in the right frontal region leading into the right frontal sinus in which there was a carious sequestrum. On examination of the nasal cavities the left was apparently normal, although the breathing space was somewhat contracted; the right nasal cavity was a little contracted, but otherwise there was not evidence of frontal sinus disease. An attempt to pass a frontal sinus catheter was unsuccessful owing to the limited space in the middle meatus, and an endeavour to remove the anterior end of the middle turbinal body met with so much difficulty that it was postponed till the frontal sinus had been investigated. An incision was made in the mid-frontal line outwards and transversely to the right to an extent of about two inches. On raising the tissues over the frontal bone a sequestrum as large as a sixpenny-piece was found covering, and opening into, the right frontal sinus. On the under aspect of this sequestrum the ridge separating the two frontal sinuses was apparent. It was now seen that the opening, which seemingly belonged to the left frontal sinus, communicated with the right frontal sinus, and that the right frontal sinus was intact. On attempting to investigate the opening corresponding to the sequestrum, which was situated over the left frontal sinus, the probe passed into the right frontal sinus. On further examination, the right frontal sinus was found to be also full of pus, and on the application of a small trephine, it was discovered that this sinus extended as far as the outer angle of the right orbit and for a considerable distance over the roof of the orbit. Mr. Collier said that here was a condition of things extremely unusual; the left frontal sinus was very small and undeveloped; the small cavity which existed communicated independently with the right nasal chamber, but the right frontal sinus was very extensive and communicated also independently with the right nasal chamber. It should be noted that the bone forming the anterior layer of right frontal sinus was extremely thin, not thicker than a sixpence. The whole interior of the right frontal sinus was full of polypoid granulations and showed considerable thickening of the lining membrane. He pointed out that in cases of this description the only hope of a radical cure rested on the removal of the anterior wall of both frontal sinuses so as to obliterate these cavities; when once the lining membrane had become so disorganised as to produce polypoid granulations little hope existed of resolution into a healthy condition. The whole of the interior was curetted and the lining membrane removed to the full extent of the sinus. The cavity was plugged with cyanide gauze and the skin adjusted, leaving a large opening over the original sinus. The opening into the nose was enlarged, and a large drainage tube inserted so as to allow free drainage into the nasal cavity.

The subsequent history of the case was very instructive. The external wound healed perfectly by first intention, leaving little or no scar. The wound drained freely into the nose, and the case proceeded satisfactorily; on the fourth day the wound was dressed, the plug removed, and drainage dispensed with, the patient's condition being all that could be wished. On the sixth day the man was sick, and the pulse below normal; there was some distaste for food, but otherwise the wound and general condition were excellent. On the seventh day the patient was examined in consultation with two physicians; the pulse now was forty-six, there was constant sickness, and the man's state was not satisfactory. The wound had healed, was free from tenderness or redness,

and there was very little discharge. The joint opinion expressed at the consultation was adverse to any further operative procedure. Mr. Collier gave instructions that if things did not change for the better the wound should be opened up and examined. This was done on the same evening. On re-opening the wound the greater part of the right frontal sinus was obliterated throughout, there was some secretion between the outer and posterior layers in the immediate vicinity of the wound. On examining carefully the posterior bony layer of the frontal sinus a small sequestrum was found. On removing this and enlarging the opening, dura mater bulged and was free from pulsation. When a needle was introduced offensive pus issued. On further opening the dura mater about two ounces of stinking pus were discharged. A drainage tube was inserted and the wound closed. It was noted that subsequent to this operation the pulse improved and rose to 120. During the next forty-eight hours the condition of the patient was satisfactory, but on the third day there was pain in the right arm complained of, with some rise of temperature; general meningitis supervened, and the patient died in the following forty-eight hours. Mr. Collier said this was a case full of instruction as far as the frontal sinus disease was concerned. A moderate sinusitis in this patient had resulted in a sequestrum in the anterior and posterior bony layers of the frontal sinus; the anterior sequestrum, as being larger and more evident, was removed, the posterior sequestrum, being quite microscopic, had been overlooked. The extreme and abnormal thinness of the bony walls was quite unusual, and had evidently predisposed the destruction of portions of the anterior and posterior walls; the peculiar arrangement of the sinuses was also, he thought, an abnormality of extreme interest; it was very rare that both sinuses should discharge into the right nasal chamber, and this, together with the association of the extremely thin bony walls, was a point in the surgery of the frontal sinuses which was well worth noting.

Royal Commission on the Feeble-minded.

ON Friday last Dr. Lionel Weatherley, Medical Superintendent of Bailbrook House Asylum, Bath, gave evidence with reference to feeble-minded criminals. He said that neither the prison nor the county asylum, as at present constituted, was a suitable place for their reception. The prison had neither a deterrent nor reformatory effect upon them. He strongly advocated a special penal colony for those who had been convicted of crime or misdemeanour, where they should be given a chance of being educated to some suitable and congenial occupation.

Presentation to Dr. Henry FitzGibbon, Ireland.

ON Thursday last Dr. Henry FitzGibbon was the recipient of a presentation from all grades of the postal service. The testimonial served to commemorate the twenty-five years' service which he has spent as medical adviser to the department, and the occasion was availed of by the various employees to give expression to their appreciation of the efficient manner in which he discharged his duties during his long and honourable association with them. The form of the presentation consisted of a massive loving cup, a silver salver, and an illuminated address. The cup was a replica of the Ardagh chalice, and was a beautiful sample of the silversmith's art. Mr. G. M. Hurley, Chairman of the Irish Post-office Clerks' Association, presided, and he and others spoke in flattering terms of Dr. FitzGibbon's work amongst members of the postal service for the last quarter of a century. Dr. FitzGibbon, who appeared deeply touched, expressed his thanks for the tokens of their affection.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JANUARY 5TH, 1906.

The President, DR. JOSEPH O'CARROLL, in the Chair.

FRACTURES OF OS CALCIS AND ASTRAGALUS.

PROFESSOR BENNETT said—One reads in the present day the old assertions about fractures repeated as if they had not been put aside by the accumulated knowledge of the last century. I take this example from a book bearing the date 1900:—"Fractures of the tarsal bones are always caused by direct violence (passing of a carriage wheel), falling of a heavy weight upon the tarsus." To put any addition to our knowledge of the fractures of the tarsus is a matter of interest in helping to wipe out the "always" from the passage I have quoted. Bad anatomy does not help us in this difficulty. "The astragalus is a peculiar bone, inasmuch as it articulates with four different bones and shows no point of insertion of any tendon." May not the horizontal division of the external lateral ligament be regarded as tendon? I regret that I am not able to state anything of the life history of the examples I record to-night, but I present them as I have them. The first of these is a left os calcis, which Professor Dixon kindly gave to me this session, because the portion of bone forming the articular surface in front of the sustentaculum tali is wanting. The specimen agrees in many particulars with the case of Legouest, figured in the thesis of A. Ballenghein (Thèse par A. Ballenghein. July 20th, 1890. Page 126), and is wanting in the fact that the little piece of bone has not been preserved. My next two specimens concern the astragalus. Some five and twenty years ago I published a discussion on the supposed fracture of the tubercle of the astragalus whether it be a fracture or not or a vestige of the ostrigonum tarsi (*Journal of Anatomy*, Vol. XXI.). I have multiplied specimens of this kind until now my series number eleven. To-night I show a united fracture of the same region of the bone, without doubt a fracture well and truly knit but how caused I cannot say. The anterior part of the tubercle with the groove for the tendon of the long flexor of the great toe has been broken and united with the minimum degree of deformity. The question which is most difficult of solution is—How did it get broken? By what force, direct or indirect? Lastly, I show a specimen which I am again very hard set to read to-night. I put this by in spirit last summer, puzzling over it to find some solution of its mysteries. While the summer passed the spirit sped away, and when I came back to my work almost all my mysterious signs of fracture had gone. See how I got the specimen. A student in his first year had dissected the lower extremity to the last shred, and he had got the astragalus isolated neatly from the bones of the leg and from the tarsus, and, seeing me pass, asked me to look at "the fracture." I agreed in his diagnosis. I said I could see no damage or trace of it in the bones of the leg or of the tarsus, and, for some reason being pressed for time, I was content to walk off with the bone. No one here would give me credence for my diagnosis of fracture had I not put the specimen in water a few days ago, and so repaired the damage of the evaporated spirit. Read the lesion as you like. A fracture it was, taking effect on that part of the head of the bone that rests on the calcaneo scaphoid ligament, and it has not passed to any deeper extent than the cartilage.

CANCER OF THE OESOPHAGUS WITH SECONDARY GROWTH IN THE HEART.

DR. TRAVERS SMITH exhibited some of the thoracic viscera of a man, *æt.* 70, who had died under his

care in the Whitworth Hospital of flat-celled cancer of the oesophagus. The growth had caused a very narrow stricture, and had grown by direct extension into the outer coat of the descending aorta. Numerous small secondary deposits were also found in the outer coat of the aorta, and the bronchial lymph glands were cancerous. Embedded in the wall of the left ventricle near the auriculo-ventricular groove was a secondary deposit the size of a large hazel-nut, which on microscopical examination, made by Dr. Earl, showed typical flat-celled arrangement. There were no metastases of the disease below the diaphragm with the exception of a cancerous deposition in a single lymph gland situated under the peritoneum on the anterior aspect of the stomach near the oesophagus, and nearer the lesser curvature than the great. Dr. Travers Smith laid stress upon the frequency with which this gland was affected in internal, especially abdominal, cancer. He also spoke of the difficulty in fully explaining how the secondary deposit in this case had reached the heart.

The PRESIDENT said that an interesting point had been raised—namely, the dissemination backwards against the lymph stream. This must often happen also in various forms of tubercle. The particle must be supposed either to have gone against the stream or else had been carried by the subclavian, returned by the vena cava and going through the pulmonary system was deposited by the coronary artery in the heart.

PROFESSOR BENNETT said the same thing must occur in cancer *en cuirasse*, as the cancer certainly did not follow the lymphatic stream.

DR. LITTLE said that in cases of tubercular meningitis the original lesion was often found in the bronchial glands so that in such cases the infection must also travel against the stream.

DR. TRAVERS SMITH briefly replied.

HYDROCEPHALUS.

DR. O'CARROLL showed a hydrocephalic brain of a boy, *æt.* 17, who had suffered for about six years from headaches and frequent sub-comatose attacks lasting a few days. The cranium was not much larger than normal, and was fully ossified. The ventricular cavities were considerably dilated, but not to the degree of thinning the brain substance excessively. The greatest thinning was at the lower anterior part of the lateral ventricle, where the cortex was adherent to the underlying bone. During the last couple of months of the boy's life a colourless watery fluid, recognised to be cerebro-spinal fluid, used to drip freely from time to time from the left nostril. No thickening or occlusion of the pial curtain descending from the cerebellum to the medulla was found. It was evident that the serous discharge from the nostril came from the left ventricle by way of the adhesion of the temporo-sphenoidal lobe to the body of the sphenoid. It is to be noted that during life the boy had been sub-normal in intelligence, but by no means an imbecile; he had learned to read and write, and could perform simple mental calculations. He was of average height and weight, and the head was not abnormally large, but the sexual organs were poorly developed. The skin, of normal texture, seemed somewhat tightly drawn over the limbs as it ordinarily is on the outside of the thigh; but there was no scleroderma. There had been no ataxy. In walking his toes caught the ground now and again, and Babinski's toe-extension sign was present, while increased knee-jerk and ankle clonus were absent. There was no proof of hereditary syphilis; his birth had been instrumental. Dr. O'Carroll suggested that, as in other cases, hydrocephalus seems to depend on obstruction of the posterior outlet of the ventricles; this may have started in obstruction of anterior fissural outlets by an early basal meningitis of adhesive character, the outlet re-asserting itself recently in the nasal drip.

Dr. EARL described the appearance of the brain on making a *post-mortem* examination. There were a number of points on the anterior surface of the temporo-sphenoidal lobes where the brain was adherent to the bone. Also at one point on the lower surface of the left temporo-sphenoidal lobe there was a thin piece of brain left adherent, a small hole resulting. The membrane over the roof of the fourth ventricle did not appear to be thickened. The ventricles of the brain were generally distended, and the foramen of Munro was much enlarged. The sella turcica was very large as a result of the ventricular distension, not of any change in the pituitary body, which was simply flattened out.

Dr. TRAVERS SMITH said that Dr. O'Carroll deserved great credit for his diagnosis, as the diagnosis of chronic hydrocephalus was often very difficult in its early stages. He described a case which he believed to be chronic hydrocephalus in a girl, *æt.* 11. She had a distressed, anxious expression, and was completely paraplegic. Knee-jerks were lost. Legs and practically the whole trunk were anæsthetic. Pupils were widely dilated. Pulse 60. He did a lumbar puncture and the cerebro-spinal fluid came away in a strong stream. It was clear, and contained no micro-organisms and practically no cells. He presumed that Dr. O'Carroll's case was one of hyper-secretion of the ependyma, and he wondered if it had anything to do with the immature sexual organs, the condition of the skin and subcutaneous tissues.

Dr. MOORHEAD described a case of his own in which hydrocephalus had occurred after pyrexia lasting for sixty days in a man, *æt.* 65. There was no obstruction to outflow, and there was increase of the subarachnoid fluid. The cerebro-spinal fluid was distinctly turbid and he cultivated the *Bacillus coli communis* from it. He regarded the hydrocephalus as due to inflammation of the ependyma.

Dr. NEIL also described a case in an infant, *æt.* 3 weeks, from which he had removed twenty ounces of cerebro-spinal fluid through the occiput.

Dr. O'CARROLL, in replying, said that although he had got no proof of syphilis in the case, he had perhaps suspected it as being the cause. He did not know whether the condition of the skin could be associated with pituitary mischief or not.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY

MEETING HELD JANUARY 17TH, 1906.

DR. J. O. AFFLECK, President, in the Chair.

Dr. JAMES CAMERON showed a strangulated testicle from a case of strangulated hernia in an infant, aged 6 weeks, successfully operated on.

Dr. DOUGLAS WILSON (Harrrogate) showed radiograms of the hands of a case of tophaceous gout.

Captain E. D. W. GREIG, I.M.S., gave a communication in the form of a lantern demonstration embodying the results arrived at by the Commission appointed to investigate

SLEEPING SICKNESS IN UGANDA.

This paper will be found in another column under the heading of "Original Papers."

Mr. GEORGE CHIENE read a paper on

STORAINES AS A SPINAL AND LOCAL ANÆSTHETIC.

After referring to the advantages which any safe local anæsthetic would present as compared with a general anæsthetic, the introduction of spinal anæsthesia with cocaine by Bier was mentioned. On account of the disadvantages attending this, Bier discontinued its use, but at a later period the method was again taken up, cocaine being supplemented by adrenalin. Later still, a new anæsthetic, storaine, had been introduced. Storaine, or hydrochlorate of amylene, was discovered by Furneau in 1904. It was prepared from tertiary amylic alcohol; its action was that of a vasodilator, local anæsthetic, and antipyretic. It could be sterilised by heat without alteration of its properties. In doses large enough to be

lethal to animals, tonic and clonic spasms, then paralysis of the legs preceded the fatal termination. Compared with cocaine it stimulated the pulse, caused flushing, contracted the pupil, and produced no tendency to syncope; it was, on the whole, much less toxic. It had comparatively few after effects; nausea, vomiting, and headache were the chief of these. Before referring to his own experience, the speaker reviewed the literature of its use as a special anæsthetic. When failure occurred probably the technique, not the drug, was at fault. For spinal anæsthesia, from 2 to 10 centigrammes of the substance, which occurred as a fine crystalline powder, were required. This should be dissolved in ten times its bulk of sodium chloride solution. An all-glass syringe was employed for the injection. The technique was very much that of lumbar puncture. After the needle was introduced into the spinal canal, a little of the cerebro-spinal fluid was aspirated into the syringe and mixed with the solution of storaine. The whole was then injected into the spinal canal. In a few minutes the patient experienced a feeling of pins-and-needles in the feet; this was followed by rapid loss of sensibility to pain, touches being still perceptible. The order in which analgesia appeared was (1) perineum; (2) toes; (3) legs, passing up over the body. In none of the speaker's cases had the loss of sensibility reached above the umbilicus. The analgesia passed off in the reverse order. In all Mr. Chiene had used storaine spinal anæsthesia in fourteen cases, with three failures. Twice he had not succeeded in reaching the spinal canal, and once he had not been able to get the storaine injected. In three of the remaining cases a limited amount of chloroform had also been required on account of an insufficient dose of storaine. He thought that the doses stated erred through being on the small side. In none of his cases had there been any unpleasant after-effects. As a local anæsthetic storaine was less powerful than cocaine, and did not seem to present any great advantage.

Dr. LUKE spoke of the risks attending spinal as compared with general anæsthesia. He had heard of three cases of gangrene of the skin from the use of storaine.

Mr. CAIRD said that spinal anæsthesia had undoubtedly come to stay. Recalling Bier's early work with cocaine spinal anæsthesia, he said that one could not fail to be struck with the fact that the patients, though they felt nothing, got into a dangerous state of collapse. Storaine anæsthesia had as one advantage that it was possible to have the patient lying horizontal, while with cocaine it was important to have the head and shoulders raised lest the drug ascend the spinal canal. He described several cases in which he had employed storaine, notably in operations about the rectum, in elderly people with heart disease and emphysema, in whom a general anæsthetic would have been risky. He had also used it for disarticulation at the hip for malignant disease. In one of his patients two hours after the injection was given, and after the operation was over, the anæsthesia extended to the neck. For local anæsthesia he preferred cocaine.

Mr. J. W. STRUTHERS spoke of the risks attending spinal cocaine-gation.

Dr. THEODORE SHENNAN read a paper on the THE RELATION OF SPIROCHÆTA (SPIRONEMA) PALLIDA TO SYPHILIS,

which we hope to publish in our next issue.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

ANNUAL MEETING AT MANCHESTER, ON JAN. 19TH, 1906.

DR. D. LLOYD ROBERTS, President in the Chair.

DR. D. LLOYD ROBERTS, delivered his valedictory address on the

EVOLUTION OF OPERATIVE GYNÆCOLOGY.

remarking that in the early days of operative gynæco-

logy the operation aimed directly at the object to be gained. He roughly estimated the difficulties and dangers to be overcome and did not elaborate improvements, the need for which was as yet unknown. Hence the early methods were crude and devoid of niceties of execution. Then improvements were added until simplicity was overlaid with complexity. The attention of later operators was given to details, to the surmounting of isolated obstacles frequently at the expense of the unities of the operation. Finally a reaction set in, complicated methods were abandoned and a return was made to primitive simplicity shorn of its crudities. Crude directness of purpose gave place to elaboration of method, which in turn yielded to that effective simplicity which represented the high water mark of applied knowledge. This central thought was illustrated by the speaker from the history of abdominal surgery in general with special reference to Casarean section. The operations for cancer of the uterus were reviewed, also those for vesico-vaginal fistula. The mode of dealing with the pedicle of ovarian tumours afforded another example of the main thought. The speaker added that the same cycle which has been observed in the evolution of gynæcological operations, is being passed through by the operators themselves. The modern gynæcologist was evolved through the obstetric physician from the man-midwife, and there was a tendency for him to give up his original function, that of attending labours. But as there must always be those who are exceptionally qualified to act as obstetricians, the primitive usage would be reverted to, and place would still be found for the obstetric physician—a specially skilled man-midwife. The value of investigations in pre-natal pathology was emphasised and this was suggested as a rich field for study for the obstetric physicians of the future.

Dr. J. B. HELLIER (Leeds) showed a pelvis deformed as a result of

INFANTILE PARALYSIS.

There was deficient development of the os innominatum of the paralysed side and the normal flattening which takes place between birth and maturity was exaggerated on the sound side on which extra weight was thrown. The left limb was four inches short and much atrophied, the left sacral plexus was atrophic, while the obturator internus and pyriformis were scarcely to be found. The patient was *æt.* 39, and had walked with a crutch. There was a difference of $\frac{1}{2}$ -inch between the oblique diameters of the pelvis at the brim. There was great contraction at the outlet; the ischial spines being $3\frac{1}{4}$ inches apart while the tip of the coccyx was within $1\frac{1}{4}$ inches of the symphysis, and deviated $\frac{1}{4}$ in. to the right.

Dr. Richard Favell, of Sheffield, was elected President of the society for the year 1906.

The following office bearers were also elected:—
Vice-Presidents: Sir William Sinclair, M.D., D. Lloyd-Roberts, M.D., Manchester; Owen Bowen, M.R.C.S., Arthur J. Wallace, M.D., Liverpool; J. Braithwaite, M.D., C. J. Wright, M.D., Leeds; John W. Martin, M.D., Percival E. Barber, M.R.C.S., Sheffield. Hon. Treasurer: E. Octavius Croft, M.D., Leeds. Hon. General Secretary: W. E. Fothergill, M.D., Manchester.

The usual dinner was held at the Queen's Hotel after the meeting. Dr. Favell in the Chair.

LARYNGOLOGICAL SOCIETY OF LONDON.

At the Annual Meeting held on January 12th, the President, Mr. Charters J. Symonds in the Chair, the following were elected as officers and members of Council for 1906:—*President*: Mr. Charters J. Symonds, *Vice-Presidents*: Dr. F. Willcox, Dr. J. D. Ball, Dr. William Hill, Dr. Watson Williams. *Honorary Treasurer*: Mr. H. B. Robinson. *Honorary Librarian*: Dr. St. Clair Thomson. *Honorary Secretaries*: Dr. H. J. Davis, Dr. W. Jobson Home. *Members of Council*: Sir Felix Semon, Mr. Philip de Santi, Dr. J. Middlemass Hunt, Mr. S. Paget, Dr. Atwood Thorne.

At the ordinary meeting, held subsequently, the following communications were made:—

Dr. W. H. KELSON exhibited a case of Sinus of the Chin, and also one of Ulceration of the Left Vocal Cord of an obscure nature occurring in a man, *æt.* 28.

Sir FELIX SEMON exhibited a patient, *æt.* 74, in whom a tracheal canula had been permanently worn for twenty-seven years for incomplete bilateral paralysis of the post-crico-arytenoid muscles which had remained unchanged all that time.

Dr. DUNDAS GRANT exhibited a case of Extensive Ulceration of the Pharynx of a Syphilitic Nature, and also skiagrams illustrating the treatment of frontal sinus suppuration by irrigation.

Dr. J. B. BALL exhibited a case of Ulceration of the Pharynx and Larynx of an Epitheliomatous Nature, the point of interest being the very early involvement of the glands and the appearance of an ulcerating mass behind the tonsil, the disease having originated in the larynx.

Dr. E. A. PETERS showed a specimen of a Tumour attached to the Base of the Sphenoid, which presented under the microscope the structure of a fibro-angioma.

FRANCE.

Paris, January 21st, 1906.

OXYGEN WATER AS A THERAPEUTIC AGENT.

PEROXIDE of hydrogen or oxygenated water is a powerful microbicide although it has no action on soluble ferments. According to Chamberland and Fernbach it acts very rapidly on the bacilli of typhus; also it destroys the bacilla of Koch. As far back as 1898, M. Redard announced at the Congress for the Study of Tuberculosis, several cases of cold abscesses, opened or fistulous, rapidly cured by applications of oxygen water. Since then he has applied this treatment to osteitis, osteo-arthritis and tuberculous lesions of other tissues.

Cold abscesses. The cure of cold abscesses by oxygen recommended by Luton of Reims has incontestable advantages over the other classical methods. Without causing any accident, it cures rapidly and permanently.

In cold abscesses—deep or ossifluent—after rigorous asepsy of the skin, the pus is evacuated by a large trocar and the following liquid, as used by M. Redard, injected.

Sol. of phosphate of soda (1-10), 3 oz.;

Oxygen water (12 vol), 1 oz.

The solution is injected slowly and removed after two or three minutes, when more is injected, and so on for three or four times until the cavity is thoroughly washed out. After the last injection a little of the liquid is left in and the opening sealed up. The operation is renewed at the end of ten or fifteen days.

Frequently one operation is sufficient; the quantity of liquid injected varies with the size of the cavity, but in general from one to two drachms are sufficient. Where the abscess is on the point of opening or has opened, the trochar is inserted outside the zone and through the healthy skin.

For closed cold abscesses, a cure is the rule, and much more quickly than with other modifying agents such as iodoform and oil, while in open and fistulous abscesses and so rebellious by reason of secondary infection, oxygen water acts better than any other substance; it modifies rapidly the infractious tracts and facilitates cicatrisation in a relatively short time. In such cases, also, Professor Thiriart, of Brussels, recommends injection of oxygen gas by means of an instrument he has invented for the purpose.

In superficial cold abscesses, tuberculous gummæ, tuberculous infiltration of the skin, injections of oxygen gas or water, act remarkably well. The same may be said of cases of osteitis, and tuberculous synovitis, especially where fistulæ exist.

The treatment by oxygen has the immense advantage

of being able to be employed without danger even in large quantities and without fear of unpleasant consequences.

CHRONIC IMPETIGO.

It is in scrofulous children that impetigo becomes chronic and the treatment should be both general and local and the latter is very important.

The crusts should be removed by compresses of boiled water and then the parts washed with the following solution:—

Sulphate of zinc, $\frac{1}{2}$ drachm
Sulphate of copper, $\frac{1}{2}$ drachm;
Camphor, 5 grs.;
Water, 20 oz.

After which, an ointment of

Starch, 2 drachms;
Oxide of zinc, 2 drachms;
Vaseline, 1 oz.

Cauterisations with a solution of nitrate of silver (1-10) give also very good results.

GERMANY.

Berlin, January 21st, 1906.

RICKETS AS A FOLK DISEASE.

THIS subject formed that for discussion at the Hufeland Society on the 8th inst. It was introduced by Hr. v. Hansemann, who first of all went over the symptomatology of the disease. Then, passing on to etiology, he observed that a view once held as to it being an infectious disease was given up, and also that the view that it was due to an absence of lime salts or sodium chloride was, on the basis of animal experiment, no longer tenable. He referred to the fact that all animals kept in captivity were rickety, so that rachitis was a "cross" of all our zoological gardens. On examining the skulls of 9,000 animals that were shot whilst in a state of freedom, rickets was not once met with. An ape living in Japan and then captured and held in captivity, showed distinct signs of rickets within six months. There was no rickets amongst Japanese children, and certain signs of rickets were never met with amongst uncultivated peoples. Inquiring after the cause, we found that Japanese children were brought up differently from our own. A further observation showed that children born in autumn and winter became rachitic, but those born in spring or summer were not at all or only very slightly so, and the disease made its first appearance even in them in the winter. The decisive factor was want of fresh air. There lay the difference, our children were tied up and kept in rooms. Japanese children get fresh air and are without bandages and clothes. Moreover, most of the houses had no glass windows, but were provided with paper air openings. Too much had been attributed to food; it did indeed influence rickets, but it did not cause it. Domestication was the cause of the wide spread of rickets. Cats that were not domesticated had no rickets; pigs that were required to become fat suffered much from it.

Heredity certainly played a certain *role*. Every individual had a tendency to become rickety.

Hr. Cassel would attribute more influence to food in the production of rickets than the previous speaker would, even if the air played the part attributed to it by him.

All injurious hygienic factors acting for lengthened periods might produce rickets. It was a well ascertained fact that a large number of children suffering from severe forms of rickets were such as were artificially nourished. The over-crowded rooms of workpeople were the breeding places of rickets, and more especially in the winter. Remedies acted better when the unfavourable time of the year was over. It was of interest that children with atrophy did not get rickets. The doing away with rickets was only a question of money.

Hr. Westenhöffer had seen no rickets worth mentioning in Silesia. The children there lived all the year in the open air. Others had made the same observation.

In spite of the bad food amongst workpeople in all Upper Silesia there was no rickets.

Hr. Neumann agreed in general with the previous speaker.

Children born two or three months before the cold time of the year were rachitic. Certainly catarrh of the bowels and air passages had an influence on the origination of rickets. Tuberculosis was also influenced by rickets. If we found a specially severe form of rickets we could assume that the child had masked tubercle. We found distinct traces of rickets amongst most of the older children of the poorer classes. Rachitic erosion of the teeth was an undoubted sign of the disease. Heredity played an extraordinarily important part. As regarded the influence of fresh air we should turn to Northern Italy, where conditions similar to those of Silesia existed. Here also children were in the open air day and night. Only in winter they shut them up in badly-built houses, and they had such severe cases of the disease that large institutions had to be built for it.

Hr. Bernhardt said hereditary rickets was rare. He has only seen one case that could be looked upon as congenital. In a Hungarian village, in which he had inspected all the children as to rickets, there were only two cases, and they were the children of the local doctor.

Hr. Cassel said it was the exception for a child not to be suckled in Japan, and in Upper Silesia, also, the children were thoroughly breast children.

ANASTOMOSIS BETWEEN PERIPHERAL END OF FACIAL AND ACCESSORY NERVES.

A case in which such anastomosis was made is reported in the *D. Med. Wochensch.* by Dr. Silk, of Hamburg.

A radical operation was performed on a man, æt. 23, for middle ear suppuration; in consequence of which complete paralysis of the facial nerve took place. This was in July, 1902. In the middle of December, the nerve was exposed below the stylomastoid foramen; it was grey coloured and very thin. It was severed, and the peripheral end united by suture to the accessory nerve. At first there was paralysis of the trapezius, and secondary stiffening of the shoulder-joint. The muscles of neck and shoulder wasted and the scapula moved with all movements of the right arm. In March, 1903, the patient was first able to raise the arm above the horizontal, and in six months there were traces of returning function of the facial nerve. In January, 1905, when at rest, there were no signs of facial loss of power, but slight weakness in both upper and lower branches. The eyes could be closed firmly, and the patient could whistle, and on laughing the right cheek contracted well. The function of both arm and shoulder was quite restored.

AUSTRIA.

Vienna, Jan. 21st, 1906.

MICROGRAPHIA.

At the "Gesellschaft" Bleier presented a nervous patient who had no hereditary taint, neither had he suffered from syphilis, but according to report he had been a heavy drinker. He was always very passionate and bad tempered, till last year when he became morose and bellicose. About this time his speech became impeded and his gait unsteady, but the most remarkable change was the character of his hand-writing which was microscopically small. When he attempts to walk now he reels or staggers and begins to run to maintain his equilibrium, which he does with short quick steps. He tells you he must run as he has the tendency of falling forward and by this means endeavours to regain his equipoise. When he rises from a sitting posture or stands this uncomfortable feeling afflicts him, but the strange part of the phenomenon is he falls backwards if not supported or supporting himself by something near him at the time. Two years ago he fell and broke the neck of the femur, which appears to have healed without any bad effect. The speech is very low, monotonous and quick, and is the same when reading

always repeating the last word of a phrase or sentence, sometimes frequently. He is quite unfit for duty as a cashier.

Bleier now produced the patient's handwriting before his present illness and that of the present time, which stood out in striking contrast. At the beginning of a word or sentence the letters though extremely small are yet decipherable, but as he proceeds the letters degenerate into an irregular line over which he has no control. His visage is notably stiff and stern, no grimaces or mimicry to relieve the sad immobile countenance.

Arterio-sclerosis and Graafe's symptom of difference in pupillary dilatation as well as tremor of the outstretched finger, with slight atrophy of the muscles of the right thigh were all present. There was also a limitation or diminution of upward vision.

ANEURYSM OF THE RIGHT RADIAL ARTERY.

Weinberger showed a patient, æt. 45, who was received into Schrötter's clinic on November 23rd, suffering from aneurysm of radial artery, presumably from a mycotic embolism. According to history no hereditary tendency was present, neither had he suffered from any disease in childhood, but he had had a fracture of the left fore-arm and another fracture of the right fore-arm in 1896. Since the last fracture he had enjoyed good health up to April last year, when an attack of rheumatism confined him to bed, going over every joint before relief was obtained. About the end of August he had a severe attack of pleurisy, confining him to bed for another four weeks. Shortly after this his right hand began to swell, accompanied with great pain, for which a bandage was prescribed. After twelve hours' application the back of the hand was seen to swell and pulsate, which soon extended over the wrist-joint. At the same time it was observed that he had pain in the left foot above the toes and was in a fevered condition; on his reception to clinic he had irregular fever, commencing with rigors and temperature rising to 40°1', falling on the same day to 39°8 and 36°. There were also small swellings over other joints of the body as well as hand and wrist. The urine was found to contain albumin, epithelial and granular cylinders. There was present a blowing sound at the apex of the cordia with slight increase in real dulness, but no accentuation of the second pulmonary sound, although the second aortic sound was increased. Over the wrists was a round swollen pulsating area, which had evidently been produced by an embolus from the endocardia forming an aneurysm in the radial artery.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH AND ST. ANDREWS UNIVERSITY PARLIAMETARY ELECTION.—By this time the electors of this constituency will have received their voting papers, and we may be allowed to urge the only form of canvass which is proper for a scientific journal—namely, that the real opinion of the university graduates be shown through a heavy poll. The issues between the two candidates are clear. Sir John Tuke, the sitting member, is a Unionist, a Tariff Reformer in Mr. Balfour's sense, and a supporter of the late Government. Mr. St. Loe Strachey, of the *Spectator*, is a Unionist (*plus royaliste que le roi*, he claims to be) and a Free Trader. Sir John Tuke has a long record of useful work in Parliament, particularly as regards education and matters medical; Mr. Strachey's views are known through his connection with the *Spectator*; he is in favour of the Scottish Education Bill. On matters of purely medical politics it seems from their answers to a

series of questions drafted by the chairman of the medico political committee of the British Medical Association, that the two candidates are practically at one. Here, of course, Sir John's first hand knowledge must stand him in better stead, though Mr. Strachey undertakes to be guided by expert opinion in purely technical matters, and is evidently in thorough sympathy with medical reform. The political issue between the candidates thus narrows itself down to Tariff Reform *versus* Free Trade; to this must be added the not unnatural desire of the medical men who form so large a proportion of the electorate to see one of their own body represent them in Parliament. Voting papers must be returned duly signed and witnessed, by February 8th, we trust that all those on the voters roll will exercise the franchise.

GLASGOW ASYLUM NURSES.—The strike of the nurses in Woodilee Asylum, to which reference has already been made in this column, was recently before the Parish Council, who resolved to support the superintendent of the Asylum in his action in dismissing the nurses, but, at the same time, not to exclude the nurses who had thus lost their posts from offices in other institutions under the Parish Council.

LETTERS TO THE EDITOR.

CONSULTANT OR GENERAL PRACTITIONER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your heading, "Consultant or General Practitioner," is to the G. P. like the pack to the hunter. Of course, the Court physician is in the wrong. Yet is the specialist always in the right? It appears to me that the G. P. wants saving from some specialists, the specialists from the Court physician, and the latter from himself. How can we obtain this salvation? By remembering as members of a learned profession that we are gentlemen, and, this being so, we must act like gentlemen. We must do to others as we wish them to do to us. Until we have learned this lesson, we should have an ethical code drawn up binding upon G.P.'s, specialists and Court physicians. How few true specialists there are we all know. Is not £2 2s. as sweet to some specialists whether earned for diagnosing a wart on the head of the pancreas, or a slight thickening of the tympanic membrane! Money still rules the world, and we are of the world worldly.

I am, Sir, yours truly,

INTERESTED.

ICELAND MOSS IN THROAT AFFECTIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I draw the attention of your readers to Iceland moss, which at one time enjoyed considerable reputation among "throat remedies" in the form of either decoction, jelly, or lozenge, and was to be found in the British Pharmacopœia as late as 1885; but it has gradually become neglected and is now rarely heard of? Recollection of its associations awakened a desire to test the clinical evidence of its traditional value, and through the co-operation of Mr. W. H. Martindale, I am able to substantiate those traditions, and have no hesitation in suggesting its restoration to a place in our Throat Pharmacopœias.

Percentage Composition of *Cetraria Islandica*.—Cetrarin, 3; lichenin, 45; amyloseous fibrin, 36; gum, 4; non-crystallisable sugar, 4; water and salts (inorganic), 8.

It will be seen that the chief component is *lichenin* (C H₂₀O₁₀), a starch-like body which consists of two elements soluble in hot water—one of which is also soluble in cold water; there is a small quantity

of soluble gum and 36 per cent. of a substance partially extracted by boiling water, called amylaceous fibrin. Cetrarin is the bitter principle readily extracted by hot water, and gives the characteristic taste to the decoction, and was probably valued as a bitter tonic.

Thus Iceland moss affords the necessary material for lubricating and soothing the mucous membrane with which it comes in contact. This quality is amply realised in the discs called "lichenoids," perfected by Mr. Martindale, who has excluded the cetrarin. They are of a size and consistence suitable for slow and passive solution in the mouth, a process by which the demulcent and lubricating properties are better obtained than by the ordinary soft jujube, which encourages rapid mastication and active deglutition. They will be found satisfactory in inflammatory and excitable states of fauces and oropharynx, especially to speakers who suffer with dry mouth and throat. As a sialagogue Iceland moss is an excellent corrective in pyrosis.

I am, Sir, yours truly,

WYATT WINGRAVE, M.D.

Stratford Place, W.

THE GENERAL MEDICAL COUNCIL AND THE ELECTION OF A REPRESENTATIVE FOR IRELAND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In compliance with the undertaking stated in enclosed Circular (Dr. Kidd's address to the medical profession in Ireland of January 16th, 1906), may I ask you, if possible, to publish the correspondence referred to?

Yours faithfully,

L. KIDD.

Enniskillen, December 17th, 1905.

(1)

DEAR DR. LAFFAN,—Will you kindly inform me if you intend to be a Candidate for the G.M.C. in February 1906?

If you are a Candidate are you willing to accept the verdict of a preliminary poll (in which every practitioner resident in Ireland shall have the opportunity of voting) as between you, myself, and any other provincial candidate there may be, the defeated candidate or candidates to unconditionally promote the candidature of the one at the head of the poll?

Apparently you are not aware of the efforts I made in March of this year to have the question of the D.R. for Ireland discussed by the provincial men.

The Circular, of which I enclose a copy, was sent to the Hon. Sec. of every branch I.M.A., and Div. B.M.A. in Ireland.

Yours faithfully,

L. KIDD.

I incline to the suggestion that the expenses of the preliminary poll, if held, should be borne by the defeated candidate or candidates.

(2)

Cashel, December 21st, 1905.

DEAR DR. KIDD,—I have been urged to go on, but as I am less interested in myself than in the cause, I would gladly submit to a preliminary poll, but from that poll our enemies the classes should be excluded. I mean by the classes those connected with any school of medicine, clinical hospital or examining board. Another way of coming at it would be to require each preliminary voter to publicly pledge himself to vote against the Metropolitan Candidate.

I agree with you that it is only by union that we can win and though you don't see eye to eye with me in the programme outlined by me in the *B.M.J.*, yet as our interests and our hates must need be the same I should hope either to convert you or to find you coming forward with equally good proposals. You can make any use you like of this.

Yours truly,

T. LAFFAN.

(3)

Enniskillen, December 25th, 1905.

DEAR DR. LAFFAN,—I regret you do not see your way to accept a preliminary poll in which every registered practitioner resident in Ireland would have the opportunity of voting. We must therefore proceed on independent lines, but I hope one or other of us will break the spell of the Dublin monopoly. I can honestly say I have done my best for the cause of Provincial Representation and repeatedly expressed my willingness to stand down in favour of a more eligible candidate.

You may not have seen the enclosed which appeared in the *Freeman*. Nor did I see any attempt on your part to justify the statement that you were opposed by "the entire Protestant element because you were a Papist."

You may remember that in 1886 you scored 195 votes and in 1901, 245. Whereas two other Roman Catholic gentlemen received a much heavier poll—namely, Dr. Corby of Cork, 528 in 1891, and Dr. Cuming, of Belfast, 787 in 1896.

Yours faithfully,

L. KIDD.

In explanation of this letter, I may add Dr. Laffan, wrote to the *Freeman's Journal*, Nov. 15th, 1905, stating "The whole Protestant element opposed me more than once for no other earthly reason than that I was a Papist."

I replied challenging Dr. Laffan to justify this statement, quoting the figures given above and saying it would seem the entire Roman Catholic element was opposed to him for some reason other than his religion.

I sent Dr. Laffan a copy of this letter as published by the *Freeman*.

(4)

Cashel, Dec. 27th, 1905.

DEAR DR. KIDD,—I regret that you should have thought proper to withdraw from your own offer. My letter was a letter of acceptance and nothing else, for nobody can call the limitation involved in shutting out from the poll supporters of the Metropolitan candidate a refusal. Evidently you are less interested in obtaining the support of the masses and in advocating their grievances than in obtaining the empty position of a seat in a hostile body. I now call on you to publish the whole correspondence, and of course I will not trouble you with any future letters. I am now as free as if none had ever been exchanged.

Yours faithfully,

THOS. LAFFAN.

(5)

December 28th, 1905.

DEAR DR. LAFFAN,—I beg to acknowledge receipt of your letter of December 27th, 1905. At present I have not the least intention of publishing the correspondence that has passed between you and myself, but if you do so I insist that you shall include the full text of my letters December 17th, 25th, and 28th, together with that of your letters to me.

I have not withdrawn from my original offer; on the contrary I still adhere to it. I asked you to agree to a preliminary poll, in which every registered practitioner in Ireland was to have the opportunity of voting. In reply you made an entirely new proposition limiting the poll to a certain class and disfranchising another class and you call this an acceptance of my offer. To this fresh proposal I cannot and will not assent, and repeat that in thus rejecting your suggestion I do not withdraw from the pledge I made at the very commencement of my canvass.

I also asked you to agree that the Candidate defeated in the preliminary poll should unconditionally support the man at the top of the trial poll—to this you did not favour me with any reply! Am I to take your silence, ignoring your published declaration against my candidature, as an "acceptance" of this condition of the preliminary poll?

Before plunging into further controversy it is due to

your reputation to justify, or failing to do so, to withdraw the statements to which I have publicly and privately drawn your attention.

Yours faithfully,

L. KIDD.

January 12th, 1906, I wired to Dr. Laffan:—

“Are you a Candidate?”

And I received the following reply:—“I am not too late. LAFFAN.”

SPECIAL ARTICLE.

SANITARY ADMINISTRATION.

WITHIN the past few weeks *The Times* newspaper has discussed editorially the question of sanitary administration on several occasions. First, there appeared an elaborate critical examination of the recently issued Annual Report of the Local Government Board; a leader upon this followed, and another leader on the same subject was published on January 8th. It is satisfactory to find the leading organ of public opinion directing its great influence towards promoting improvement in public sanitation. The exposure which it makes of the defects and weaknesses in the laws, and in the methods of putting them into action cannot fail to have some effect in bringing about reform.

The Times reiterates the statement—it indeed employs precisely the same terms on two occasions—that “not only may something like one-half of the actual annual mortality of the Kingdom be regarded as preventable, but that it would actually be prevented if the provisions of the existing laws were adequately carried out by the various authorities upon whom the duty of enforcing them has been imposed by the legislature.” When it comes to suggesting remedies for this truly murderous disregard of duty, *The Times* seems to fail curiously in recognising facts. It expresses pity for the unfortunate citizens and ratepayers who suffer from the existence of preventable disease, and puts the blame entirely upon the local authorities. It seems to forget that the authorities are what citizens and ratepayers choose to make them. *The Times* suggests that the ratepayers at present have no remedy, and suggests an alteration in the law, compelling authorities to co-opt into their body persons possessing special knowledge of the subjects with which they would be officially called upon to deal. The remedy and the only complete remedy is to turn out inferior members of local authorities and replace them by men imbued with public spirit, and not capable of sacrificing the welfare of their fellow citizens through ignorance, if not in pursuit of selfish and sordid ends. This remedy is in the hands of ratepayers. It is their fault and their shame that it is not applied; and were it not that disease falls upon the innocent and guilty alike one might be inclined to look with cynical eye upon some communities affected with epidemics due entirely to their own failure in the duty of citizenship. The fundamental fact to be faced is, that throughout the Kingdom the educated and cultivated classes, the men of light and leading, or at least of sufficient intelligence to appreciate the importance of modern sanitary science decline as a mass to serve on local governing bodies, or to take any sufficiently active part in electing members of those bodies. Councils throughout the country, urban and rural, are all very largely composed of, and very often dominated by, mean, ignorant and vulgar men. If they attend to the letter they disregard the spirit of all the Acts of Parliament they are morally bound to administer. It would be easy to fill some columns of your space with illustrations of this state of things. Look, for example, at the position of the Medical Officer of Health and the Sanitary Inspector. They are often engaged and paid to give only a small part of their time to their duties, and are unable to exercise supervision to any adequate extent, much less to keep themselves acquainted with the minute sanitary conditions of their districts. These officers are often really the servants of a body of men, many of

whom obtain seats upon the authority with the set purpose of placing difficulties in the way of active sanitary administration. Enforcement of sanitary laws is not compulsory, and the Local Government Board has no power to coerce the authority. The Medical Officer may remonstrate in private with his committee when flagrant neglect of duty is displayed; but it is as much as his place is worth to make any public protest or put himself in open antagonism to his employers. He knows very well that when the authority is dominated by a certain class of men it is because there exists no public opinion to which an appeal can be effectually made, and that such an appeal would sooner or later lead to loss of his position, or at least to the docking of his miserable stipend. Democratic institutions such as ours cannot be administered properly unless the bulk of intelligent citizens take due interest in their working. There exists in these islands very little of the municipal corruption such as disgraces the United States, but the prevailing apathy, the lack of local patriotism, the disinclination to make any personal sacrifice for the good of the community, constitute a danger to the State. They form one of the larger signs of the times that go to justify the pessimistic estimate of latter-day society which many thoughtful observers now so frequently adopt.

NEW SURGICAL APPLIANCES.

PLEATED AND COMPRESSED DRESSINGS.

MESSRS. BURROUGHS WELLCOME have brought out a series of compressed dressings that should be of value to surgeons and general practitioners. They comprise lint, bandages, gauze of various kinds, Esmarch's triangular bandage, and other surgical requisites. The idea is excellent. Suppose the surgeon requires, say, some sublimate gauze for a dressing, he takes out an oblong packet a few inches in length, and removes its outer covers of tin foil and parchment paper. A good supply of sterilised gauze compressed into a small compass is there ready to his hand. One advantage is that supplies of all kinds can be stored in this way without deterioration. The latest addition to the series is a pleated compressed “S.T.” or sanitary towel for the use of women. They possess the characteristics of the ordinary towel, but have the great additional advantage of economy in the amount of space needed for packing or storage. This article should become popular, as it is extremely apt and ingenious.

The Richmond Asylum and the Public Bodies Order.

At the meeting of the Committee of Management of this hospital last week, the application of the Local Government Board for a mandamus to compel the Committee to comply with the public bodies order was under discussion, and the Chairman mentioned that he had communicated with the new Chief Secretary. The latter has replied that the matter was receiving his attention; and in the meantime the Committee has not been served with any further notice regarding the mandamus. It appears that the Committee has some reason to complain of discourtesy on the part of the Local Government Board, as the first intimation that a conditional mandamus was to be applied for was the notice in the daily papers that it had been granted. The Committee approved the action of the Chairman, and now awaits a further move on the part of the Board.

The Council of the University of Sheffield have appointed Dr. Louis Cobbett Professor of Pathology. Dr. Cobbett received his medical education at Trinity College, Cambridge, and afterwards at St. Thomas's Hospital, London. He is a graduate in Arts and Medicine of Cambridge University, and a Fellow of the Royal College of Surgeons of England.

REVIEWS OF BOOKS.

JOHN BULL AND JONATHAN. (a)

THE author of these interesting and amusing reminiscences is well known in what we may call the medical commercial world, and they will be read with pleasure by professional and non-medical friends on both sides of the herring-pond. Mr. Richards, although a born American and presenting almost all the best characteristics of the Yankee, is, by nearly forty years' residence and business associations in this country, a thorough admirer and loyal supporter of British men and methods. He writes, as he himself declares, from a British-American standpoint. Much of the volume is concerned with attractive and frequently humorous personal experiences in both countries, and he sketches in clean-cut, incisive language, the difficulties and pleasures which have met him in his social and business relations. He describes contrasts and criticises manners and methods of life in the two countries in such a way as to afford material interesting to the dwellers in both. Mr. Richards has played an active part in the introduction and sale of proprietary medicines in this country, and we could have wished that he had discussed the ethics of "quack" preparations as the physician is wont to regard many of the so-called American nostrums. We fear, however, that the author would find difficulty in viewing the matter from the old-fashioned medico-ethical standpoint, for he says, "after an experience of over 50 years, I consider that advertising as a profession is the most fascinating form of speculation in existence." Mr. Richards, however, has an affection for the English physician, for he says, "of products of 'Advanced Pharmacy,' mention must be made of the ready recognition on the part of the medical profession of Great Britain of the improved method of preparing drugs for accurate dispensing which has been introduced by American manufacturing chemists and pharmacists." Public praise is here accorded also to the author's family physician "for his professional skill and services and warm, friendly interest in our welfare at all times and in all ways." This gentleman, whose name is given, has, we are informed, "retired from active practice, and has removed from London to Brighton, but still attends upon old patients and friends when possible." The author, like most business men, has failed to understand the intricacies and perplexities of medical "qualifications," and his description is not unlikely to mislead our American cousins, as will be seen by such a quotation as the following:—"In reference to the practice of medicine in England, no man may style himself a 'doctor' unless he has passed the examinations by the Royal College of Physicians and Surgeons." But in spite of a degree of liberty and license, which will take away the breath of the old-time practitioner, this is a book which, with its quaint stories, laughable anecdotes, amusing experiences, and striking records of men and things, fascinates the modern reader. We have no hesitation in recommending the work to all who relish crisp and critical portrayal of modern life.

HYGIENE. (b)

THE fact that since 1894, the date of the first edition, this work has passed through six editions places it beyond the reach of reviewers and gives it a position in public esteem which can only come from proved service and experienced usefulness. The first issue of this book was in answer to a call for a concise and yet fully expressed manual of the facts and principles of hygiene set forth in simple language suited for both non-professional and professional readers. The work speedily became an accepted favourite, both with students and teachers, and quickly occupied a place among the most

popular handbooks for those preparing for the examinations in Advanced Hygiene of the Science and Art Department, the duties of which are now undertaken by the Board of Education. The present edition has been completely revised, in many parts re-written, and such new matter has been added as to make it thoroughly up-to-date, and in every way suited to the requirements of the present-day student. The general plan of the book has been somewhat broadened, and thus the needs of a wider circle of students will be met. The most marked improvements are in the sections dealing with water examination, foods, and the infective diseases. The essential facts regarding the bacteriological examination of water supplies and the still but ill-understood subject of immunity to disease are well summarised. Without being in any way exhaustive, the work forms a comprehensive and thoroughly reliable introduction to a subject, which, perhaps, beyond any other, forms the basis of individual efficiency and national well-being.

Dr. Lane Notter and Professor Firth are not only experts in their subject but experienced teachers, and the former now holds the post of Examiner in Public Health to the Universities of Cambridge, Manchester, and Liverpool. And thus the authors of this admirable manual, knowing the needs of examiner and examinee, have provided a guide which will serve the average medical student as well as give an excellent volume of instruction for the general reader.

THE SIMPLER LIFE. (a).

THE mission which Dr. Saleeby has chosen for himself is surely one which should—if only and effectively taught—prove of special importance to the rising generation. The lay literature of the British Press has been recently so fertile in discussion of the lowering incubus of physical deterioration that attention to one of the most probably rational means of its prevention must be regarded as a duty of every philanthropic citizen of our vast Empire. The text of the booklet is divided into two parts:—(1) The Poor as seen by the Physician; (2) The Well-to-do as seen by the Physician. The first part discusses in six chapters the multitudinous terrors of the life-pilgrimage of the poverty-stricken denizens of our overcrowded slums; the second deals in thirteen chapters with the torture of the existence of the over-fed and over-dressed; who probably succeed in making their lives quite as miserable as those of their ill-fed, ill-clad, and ill-ventilated brethren and sisters. There is an immense amount of sound advice and concentrated information contained in the pages of this little volume; so much, indeed, that it would be idle to attempt to criticise the contents in detail. In presence of the facts "that 77 per cent. of our population now live in cities, as against about 50 per cent. half a century ago, and the city is the maker of poverty"—the conditions so well described by Dr. Saleeby should surely command the most active attention of the leaders of a democratic community. With regard to the still more hopelessly incurable ills which are so prone to attend luxuriant prosperity, our author places his best expectations on the psychological attainments of the medical adviser. We are delighted to observe that this last chapter of all bears the inspiring title of "How to Use a Doctor." And he informs his readers, we think, very truly, that "The proper way to use the doctor—the ideal doctor, who probably is nowhere yet to be found—is to seek his advice—it need not be followed—in relation to such important matters as habits, work and play, marriage, parenthood." We close this notice of what we regard as a very important contribution to the popular medical literature of the period by recommending its contents to the best consideration of all readers.

(a) "With John Bull and Jonathan. Reminiscences of Sixty Years of an American's Life in England and in the United States." By John Morgan Richards. Pp. xiv., 302, with illustrations. London: T. Werner Laurie. 1905. Price 16s. net.

(b) "Hygiene." By J. Lane Notter, M.A., M.D., and R. H. Firth. Sixth Edition. Pp. xiv., 491. London: Longmans, Green and Co. 1905. Price 4s. 6d.

(a) "The Doctor and the Simpler Life." A Series of Medical Criticisms on the Every-Day Habits of Various Classes of the Community." By C. W. Saleeby, M.D. London: The Pall Mall Press, 1905. Pp. 95. Price 1s.

BRUCE ON MATERIA MEDICA (a).

THE present edition of Dr. Bruce's well-known work completes the forty-seventh thousand of the book—a record of which any author may well be proud. In it, the text has been subjected to the most thorough revision, and as a result is brought up to the level of the most recent medical knowledge. In addition to this revision an entirely new part has been added containing an account of the drugs of the Indian and Colonial Addendum of the British Pharmacopœia. Further, a very considerable improvement has been made by introducing greater detail respecting the chemical and pharmaceutical relations of the individual drugs. We are confident that in its improved form Dr. Bruce's work will more than retain its old popularity, and we have great pleasure in cordially recommending it as a comprehensive and reliable guide both to students and medical practitioners.

LITERARY NOTES.

In *Who's Who Year Book for 1906*, pp. 132, published by Messrs. A. and C. Black, London, we have the tables formerly included in the well-known "Who's Who." In spite of the large number of year books now available, there is undoubtedly a place for these ready reference tables. The Editor is evidently shy in approaching matters medical, and he has reason, for as he tells us, "at the request of the British Medical Association, the table of leading London specialists which appeared in the last issue, and was found very useful by the public, has been deleted." A list, however, is given of the hospital staffs of the twelve large general hospitals, but there is no reference to the many important special hospitals, and no notice of any medical schools. In the list of medical publications, the MEDICAL PRESS AND CIRCULAR is omitted, although the oldest medical weekly but one in existence, whilst the names of several but little known medical periodicals appear. In the list of learned societies also, the Medical Society of London, although the oldest and perhaps the most important, is omitted altogether, whilst such composite societies as the Medico-Legal, and the Society for the Study of Inebriety find a place. There is a useful list of "Chairs of Professors of the Universities in the United Kingdom," which, as far as medicine is concerned, seems remarkably accurate and complete, and the whole work, in spite of the omissions to which we have referred is excellent, both in its matter and arrangement.

Medical Homes for Private Patients, a classified directory, with lists of medical consultants and specialists, by R. Pritchard Binnie (London: Scientific Press, Ltd., 1906) is clearly a speculative advertisement, although said to be "the outcome of a suggestion by a leading member of the medical profession." It is claimed that this little directory has been arranged for the use of both medical men and their patients. It contains lists of medical, surgical, and invalid homes, sanatoria, hotels, hydropathic establishments, health resorts, and names and addresses of English practitioners in fashionable places abroad. A considerable section of the work is, however, a list of consultants which its authoress Mrs. Pritchard Binnie expresses the hope may be found useful to "Country Practitioners and others," although it is not explained who these "others" may be. The sins of omissions and commission are sufficiently conspicuous to discount any claims its compiler may make for it as a reliable guide, and as the profession already has available in the official *Medical Register* and the authoritative *Medical Directory* an adequate list of "consultants," "specialists," and

(a) "Materia Medica and Therapeutics: An Introduction to the Rational Treatment of Disease." By J. Mitchell Bruce, M.A., LL.D., M.D., F.R.C.P., Consulting Physician to Charing Cross Hospital. New and enlarged edition, revised throughout, and containing the Indian and Colonial Addendum to the British Pharmacopœia. London: Cassell and Co. Pp. 632.

"every other variety" of medical practitioner, the necessity for this incomplete and selected list is not apparent.

"ELECTROLYSIS in the Treatment of Facial and other Blemishes" is the title of a *brochure* by Mr. J. D. P. McLatchie, M.B., which may be found of service by those unaccustomed to dealing with the conditions of which it treats. It is short and practical, the author having a thinly-veiled aversion to discussing pathological questions connected with his subject, and evidently preferring action to thought. Within the limits to which Mr. McLatchie confines himself—he is accurate

OBITUARY.

FLEET-SURGEON JOHN P. J. COOLICAN.

WE regret to announce the death of Fleet-Surgeon J. P. F. Coolican, of Clarinda Park, Kingstown, on January 15th. He had served on H.M.S. *Thetis* during the South African War, and had been awarded the South African Medal. Owing to failing health he retired some time after. He was well-known in Dublin and was married to the daughter of Sir George Moyers, D.L., a prominent resident in Kingstown.

H. J. P. SPRENGEL, PH.D., F.R.S.

THE death occurred suddenly on Sunday at 54, Denbigh Street, S.W., of Dr. Herman Johann Philipp Sprengel, the inventor of the mercury air-pump. He was born in 1834 near Hanover, and was educated at the Universities of Göttingen and Heidelberg, where he took his degree of Ph.D. in 1858. In the following year he came to England, which henceforth he made his home. For three years he was an assistant in the chemical laboratory of Oxford University; then, coming to London, he worked in the laboratories of Guy's and St. Bartholomew's Hospitals. In 1865 he became partner in a firm of manufacturing chemists in London but retired in 1870. He was elected a Fellow of the Royal Society in 1878. He is best known scientifically for his air-pump, which he described to the Chemical Society in 1865. It was destined to have a far-reaching importance, inasmuch as it permitted Crookes to carry out his researches of the phenomena of electrical currents in high vacua, and Swan to introduce his electrical incandescent film lamp.

DR. WM. A. WEST, OF SYDNEY.

News has just reached this country of the death of Dr. William Augustus West, at Sydney, New South Wales, at the early age of forty-six, from pneumonia followed by pleurisy and heart affection, to which he succumbed on Dec. 11th, after six weeks' illness. Dr. W. A. West was the youngest son of the late George White West, barrister at law, of Ardenode, Co. Kildare and qualified for the medical profession in Dublin. He then left for Sydney, where he became assistant to, and afterwards partner with, his brother, Dr. Arthur Annesley West, who was practising at the Glebe, a suburb of Sydney. When Dr. Arthur West died in 1885, he continued the practice alone, and was highly esteemed for his kindly disposition, during the twenty-two years he spent in the district. He leaves a widow and two children to mourn his loss.

ROBERT LAIDLAW, M.A., M.B.

MUCH regret was felt throughout Fifeshire by the death of Dr. Robert Laidlaw, Ladybank, after a week's illness. The deceased was the son of Mr. Laidlaw, of Yarrow, where he was born in the late fifties. Dr. Laidlaw went to Ladybank about twenty-one years ago, and was well-known throughout the kingdom for his sympathetic and genial disposition. During that period he had built up a considerable connection and practice, and was, so to speak, in the prime of his life, though never robust. He was educated medically at Edinburgh University, where he graduated in December 1875. He was medical officer for the Parish Council of Ladybank and Collesie.

MEDICAL NEWS IN BRIEF.

The British Gynaecological Society.

THE Annual Dinner was held at the Café Monico on Wednesday, January 17th, Dr. Alexander, president, in the chair. The gathering numbered about fifty, including guests and a fair sprinkling of ladies. After the usual loyal toasts had been proposed by the President, and heartily responded to, Dr. J. W. Eden gave what might be regarded as the toast of the evening, namely, that of the Gynaecological Society; following on with a few words devoted to his own "anticipatory nervousness" and consequent loss of "gustatory sensibility" occasioned by the task before him, he spoke of the good work done by the Society. Gynaecology, he said, had now passed into a branch of general surgery, but as obstetrics were a branch of gynaecology, he was glad to see signs of reconciliation between the obstetrical and the gynaecological societies. The president responded in a few well-chosen words, in which he referred to the twenty-one years work done by the Society and to the eminence of his predecessors in the chair. He mentioned that the Gynaecological Society had given consent at a general meeting to its amalgamation with the Obstetrical Society, to form a branch of the proposed Royal Medical Society or Academy, and ended with a few graceful words of thanks to the secretaries who had worked with him. Dr. MacNaughton Jones then proposed the "Services"; this toast was answered in an excellent speech by the Director-General Army Medical Department. The last toast was that of "The Visitors" proposed by Mr. Bowreman Jessett (the incoming president), and responded to by the President of the Hunterian Society and by Mr. Reginald Harrison. Between the toasts a very enjoyable musical entertainment was given, Mr. Astley Weaver being especially noticeable in his amusing sketch.

Is Distilled Water a Drug?

MR. PLOWDEN, at Marylebone, on the 12th inst., heard an interesting case in which Edward Dunn, a chemist, of 218, Kentish Town Road, was summoned for selling a drug (distilled water) to the prejudice of the purchaser, the water being impure. Sir Thomas Stevenson, Home Office Analyst, said he found it to be very dirty and full of mouldy growths—low vegetable living organisms. In his opinion distilled water was a drug used in the preparation of medicine. People sometimes drank it medicinally. Defendant said he had been in business twenty years, and sold the distilled water in the same condition as it had been supplied to him by a wholesale house. He did not ask the purchaser what it was to be used for, but assumed it was for photography. He should have used the water if he had had to dispense a prescription, because he was under the impression that it was pure. On the point being raised, Mr. Plowden held that the article was a drug. The defendant's character had not been affected, but fraud, or no fraud, a purchaser was entitled to receive the article in a pure state. He fined defendant 10s., and ordered him to pay three guineas costs.

Workhouse Equipment.

AT the Middlesex County Asylum, Tooting, Mr. Troutbeck held an inquiry concerning the death of Louisa Sarah Withers, fifty-two, wife of a coachman, of the Quadrant, Kensal Green. It appeared that the deceased was taken ill on Boxing Day with bronchopneumonia, and a day or two later she was removed to the Willesden Infirmary in Acton-Lane. On Tuesday, when, according to the evidence of a nurse, the patient was in a dying condition, she was removed on a horsed ambulance to the asylum, a distance of ten miles, the journey occupying an hour and a half. Death took place on Thursday morning. Dr. Alfred Webster, medical officer at the Willesden Workhouse

Infirmary, said the removal of the patient was absolutely necessary owing to the fact that they had no resident medical officer. He thought her transference to the Asylum was her only chance. At the workhouse her chance was *nil*, for the reason that he had mentioned. The Coroner: That is a serious criticism of your Institution, is it not?—I think not. It is unfortunate that we have not the accommodation. He added that he had no nurse with whom they could properly entrust a patient like the deceased, although their nurses were thoroughly trained. The jury returned a verdict of death from natural causes, and said that no blame attached to Dr. Webster or the nurse, but they were of opinion that there should be a resident medical officer at the workhouse.

Threatened Revolt of Nurses.

IN the rooms of the Medical Society of London, a special general meeting was recently held for the purpose of giving consideration to the re-drafted Bill of the Association for the State registration of trained nurses. There was a large attendance, presided over by Dr. Bezly Thorne. The Bill provides for the registration of nurses, and contains clauses making provisions for existing nurses, deals with nurses trained in the Colonies, provides for the constitution of a central board, together with penalties for obtaining registration by false representation and for the wilful falsification of the registers. The meeting dealt with the various clauses *seriatim*, and a number of amendments were considered. In connection with the clause which deals with the constitution of the Central Board, and which provides for the appointment of a number of medical practitioners. Mrs. Bedford Fenwick raised strong objection. She contended that nurses ought to be represented only by nurses, and said it was an injustice to put such a small proportion of nurses on the board to manage their affairs. An amendment to this clause was defeated, and eventually the Bill, with some slight modifications, was adopted.

Instruction in Military Surgery for Civilians.

THE first lecture of the series of Army medical duties to which we have previously referred, was given at the West London Hospital on Saturday last by the Director-General, Surgeon-General Keogh, C.B., before a large audience of medical practitioners, and proved exceedingly interesting. At its conclusion a vote of thanks was proposed by Mr. McAdam Eccles, F.R.C.S., seconded by Dr. Seymour Taylor, and voted enthusiastically.

Help for the Seamen's and Poplar Hospitals

H.M.S. "BLACK PRINCE," the latest and most powerful type of armoured cruiser, will be on view in the Victoria Docks, London, at a small charge, on Saturday afternoons, January 27th and February 3rd; also on Sunday, February 4th. The proceeds will be given in aid of the Seamen's Hospital Society (Greenwich and Albert Dock), Poplar Hospital and West Ham Hospital. It is hoped that the public will largely avail themselves of this unique opportunity of inspecting an up-to-date war vessel ready to be commissioned, thereby helping these exceptionally useful and deserving hospitals.

Society of Apothecaries of London.

THE following candidates have passed in surgery:—J. A. Kilpatrick (Section II.), S. Zweiback (Section II.). In Forensic Medicine:—L. C. W. Brigstocke. In Midwifery:—J. P. E. Henery, C. Mulholland, H. F. Wight. The L.S.A. diploma of the Society has been granted to the following candidates, entitling them to practice medicine, surgery, and midwifery:—J. A. Kilpatrick and S. Zweiback.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for the MEDICAL PRESS AND CIRCULAR.

THE RECENT LITERATURE OF ANATOMY, PHYSIOLOGY AND PATHOLOGY.

Experimental Production of Aneurysms.—Erb (*Arch. f. Exper. Path. u. Pharm.* Bd. 53) has worked with rabbits to determine the effect of repeated intravenous injections of adrenalin solution. From .1 to 1 c.c.m. of a 1-1000 solution was injected daily, some of the animals exhibiting a daily reaction, while others soon acquired tolerance. The autopsies showed in most cases the signs of acute adrenalin poisoning, namely œdema and hæmorrhagic infarction of the lung, hæmorrhagic exudates in the pleura and peritoneum, and cardiac hypertrophy. The most interesting organ, however, was the aorta, which throughout its whole length but especially in its thoracic portion, showed numerous saccular dilatations, the walls of which presented atrophy of the middle coat, with here and there calcareous deposits. Further investigations seemed to show that the aneurysms were partly produced by the general rise in blood pressure, and partly by a direct toxic effect of the adrenalin on the arterial walls. M.

Pathological Effects of Radium.—Now that radium is being used in the treatment of malignant disease, the pathological influences that it can exert are of much interest. London (Berlin. *Klin. Woch.* 1905. No. 42) has investigated them in rabbits, which were confined in a small cage in the centre of which was suspended 25 m.g. of radium bromide. Nothing was observed until the sixteenth day, and then some reddening and hyperæmia of the ears appeared. This was soon followed by desquamation of hair, and by the development of ulcers and local hypertrophy of the surrounding tissue. General apathy and slowness of movement was observed after some months' exposure, and also loss of weight and retinal changes. The animals were killed after 16 months, and at the autopsy the spleen was found to be shrunken to $\frac{1}{4}$ th of its normal size, and to contain very few white cells; the lymph glands were also small and contained few cells; the liver was fatty; the kidneys showed cellular atrophy, the testes did not contain any spermatozoa, and the epithelial elements were degenerated; in the central nervous system also atrophied ganglionic nerve cells were found. M.

Worm Toxines.—Boycott (*Journ. of Path. and Bacteriology*, Aug., 1905) has conducted some experiments bearing on the question of the toxicity of worms. There is much doubt and disagreement of opinion on the subject which the present report does little to allay. We are compelled to assume, at least on the part of some worms such as bothriocephalus and ankylostoma, the production of a poisonous secretion, since in no other way can we account for the severe constitutional effects of their presence in the body. Haldane, too, has shown us that the anæmia of ankylostomiasis is almost entirely an hydræmic plethora, and in no way resembles an anæmia due to repeated small hæmorrhages. Calmette and others have described a hæmolytic action on the part of extracts of bothriocephalus, and ankylostoma. The eosinophilia so commonly observed in the presence of most intestinal parasites seems to point also to the entrance of a toxin into the blood of the host though in the case of certain worms no eosinophilia occurs. There has also been some experimental evidence on the point. Calamida produced an extract of *tænia* possessing toxic results of extreme severity; Cattanis by keeping live *ascaris* in alkaline broth produced a sterile fluid toxic to guinea-pigs. Other observers, however, were unable to confirm these results. Cao, Jammes and Mandou were unable to satisfy themselves that the sterile juices or extracts of either *ascaris* or *tænia* had any toxic effect whatever. Boycott's results, as detailed in the present paper, are practically entirely

negative. He experimented with *ascaris lumbricoides*, *tænia solium*, *tænia mediocanellata*, *tænia* from a cat, *tænia* from a lamb, round-worms from a cow, and nematodes from a dog-fish. Extracts were made by grinding with sterile sand, having washed well in running water. As far as possible undiluted juices were used, but where necessary a small quantity of sterile saline fluid was added. Inoculations were made on fifty-six animals, consisting of ten mice, eleven guinea-pigs, and thirty-five rabbits. Of these animals there died six mice, no guinea-pig, and eight rabbits; the rest presented no symptom of weakness beyond the temporary dyspnoea and weakness which is commonly associated with any but the smallest intravenous injections in the rabbit. None of these fatalities followed the use of filtered sterile extracts. The deaths of the six mice, and of three of the rabbits were proved to be due to infection. The other rabbits, except one, are excluded on other grounds, so that in only one case is there a suspicion of the action of a worm toxin. These experiments seem to discredit the results of Calamida and Cattanis, so that for the present our belief in worm toxins must rest on a *priori* grounds. R.

Paroxysmal Hæmoglobinuria.—Eason (*Edinburgh Medical Journal*, January, 1906) has made a valuable contribution to our knowledge of the pathology of a condition but little understood. This has been rendered possible by the fact that our views of the biology of the blood are now—owing to the researches of Ehrlich and Bordet—much wider than when Chvostek wrote his monograph in 1894. Eason began with the working theory that we had to do with a hæmolytic and that, therefore, the action of the serum of a patient suffering from paroxysmal hæmoglobinuria should be tested for hæmolytic with normal blood. Having such a patient at his disposal, he adopted the simple technique of procuring serum from a blister produced by cantharides, and adding to the serum thus obtained a few drops (1) of normal blood, (2) of blood from the same patient. After sixty minutes' action of the serum on normal blood, many changes were evident. The red cells had altered in colour, size, and shape, and in many of them globules of hæmoglobin had formed. In many cases active phagocytosis of the red cells was in process, the red cells being apparently "nibbled away" by the white. This phenomenon corresponded exactly to what has been observed by Ruziczka and Gruber, in the case of red cells which are loaded with intermediary body. Eason concludes (1) That a pathological substance is present in the serum of subjects affected with paroxysmal hæmoglobinuria; (2) that this substance can dissolve corpuscles, either of the affected individual or of normal subjects, in suitable conditions of temperature; (3) that low temperatures aid the hæmolytic action; (4) that the phagocytic activity observed resembled that seen by Ruziczka, Gruber, and others, in their work on immunity, an action which they considered was due to the antecedent union of intermediary body with red corpuscles; (5) that the intermediary body of paroxysmal hæmoglobinuria requires the presence of a thermolabile complement for hæmolytic to occur; (6) that the serum of normal subjects does not cause hæmolytic. R.

Malignant Disease of the Testicle.—Foulerton (*Lancet*, December 23rd, 1905) discusses the pathology of malignant disease of the testicle; and is in favour of the view that in most cases the disease is a columnar carcinoma. He criticises (1) the common diagnosis of sarcoma, (2) Schlagenhafer's view that many cases of malignant disease of the testicle are in reality "malignant teratomata" analogous to chorion-epi-

thelioma in the female. The first view he believes to be based on the fact that the disease often occurs at an early age, and on certain histological peculiarities which are frequently met with in mesoblastic connective-tissue stroma of columnar-celled carcinoma of the testicle. It may be claimed, however, that as the epithelium of the seminal tubes is, in the opinion of most embryologists, derived from the germinal epithelium which is at one time part of the mesoblastic lining of the pleuro-peritoneal cleft, that therefore growths springing thence should, on account of their mesoblastic origin, be classed as sarcomata. In reply to this doctrine, Foulerton urges that this mesoblastic origin has never been demonstrated, and that the conception of the formation of a gland by the coalescence of tubules of mesoblastic and a tube of epithelial origin involves an anomaly in development. He therefore thinks that, in spite of embryological difficulties, these growths should be classed as carcinomata, inasmuch as they resemble in all essential particulars carcinomata arising elsewhere, and they arise in what both anatomists and physiologists regard as epithelium in spite of its reputed mesoblastic origin. (2) In distinction to chorion-carcinoma, Foulerton points out marked differences in the appearance of the cell in the two kinds of tumour. The polyhedral cells of tumours of the testicle have a sharply defined outline, a protoplasm which stains lightly, relatively small nuclei, whereas in chorion-carcinoma the cells are badly defined, the cell-body stains deeply, and the nuclei are large and irregular in shape. In explanation of the occasional occurrence of cartilage in tumours of the testicle, which some think is suggestive of a teratological origin, Foulerton points out that chondrification is in no way peculiar to malignant tumours of the testicle, since it occurs in carcinomata in other situations, as well as in simple adenomata in the testicle. Moreover, it is possible that its relative frequency in the testicle is due to an assumed bio-chemical stimulus dependent on the secretory activity of seminiferous epithelium acting on the neighbouring connective tissue.

R.

Recent Cancer Research.—Bashford (*Brit. Med. Journ.*, December 9th, 1905) gives an interesting and valuable summary of recent progress in cancer research, based for the most part on the work done under his direction in the Laboratory of the Imperial Research Fund. When the work of the Research Fund was started three years ago, our knowledge of cancer was in such a chaotic state that it was necessary before all else to attempt to arrive at certainty on preliminary matters. For this purpose five questions became objects of inquiry:—(1) to define the extent to which cancer occurred among the civilised and uncivilised races of man; (2) to determine the extent of its distribution among animals; (3) to ascertain if it were transferable; (4) to demonstrate that experiments made with cancer in animals would give conclusions applicable to cancer in man; (5) to ascertain the uses of statistics, and to define the data on which they should be based. On most, if not all, of these points, some amount of fixed knowledge is now available as a foundation, whereon to build. (1) The ethnological distribution of cancer is as wide as possible. There is probably no race, however untouched by Western civilisation, exempt. (2) Among vertebrate animals, wild and domesticated, the disease is widely distributed. Malignant new growths have been investigated from birds, tame and wild; from mice, from trout in hatcheries, from carp, from marine fish in a state of nature, from frogs, from a lioness, from a tigress, and from a marsupial. Up to the present a true malignant growth has not been described in a reptile, but evidence was bound to be late in the case of certain groups, and there is no reason to suspect that cancer in reptiles will not be eventually discovered. (3) Cancer is transmissible, but only under very favourable circumstances, and only from one animal to another of the same species. In fact, it is only in the case of mice that transmission has been successfully practised. Moreover, the cancer of a tame mouse will only grow well in other tame

mice of the same race, that of a wild mouse in other wild mice of the same race. The cancer of a tame or wild Danish, German, or French mouse, grows with difficulty or not at all in an English mouse of corresponding race. Its transmission naturally is very improbable, and in no case was cancer accidentally transmitted from diseased to healthy animals, although housed together. In this point of transmissibility, therefore, cancer differs markedly from the diseases known to be infective. It has been established, too, that whereas cancer cells when transplanted continue to live as individuals, the stroma cells speedily die; nevertheless, the cancer continues of the original type. Moreover, whereas cancer is much more common among the aged, it can be implanted in the young with greater ease than in the old. (4) The histological structure of cancer as found in man and in animals is identical. Moreover, it has the same marked association with old age throughout the vertebrates. Bashford states some general conclusions mostly of a negative nature, which he thinks may now be agreed on. Judging from the difficulty of transmitting cancer from mice of one race to mice of another, it is unlikely that the prevalence of cancer among such races as the negroes of America has been brought about by contact with white men. Still less can it be held that the white man is the focus whence cancer has spread to the lower animals. The wide distribution of cancer among men and animals show that the old theories based on geological, climatological, and dietetic considerations must be abandoned. There is evidence, too, against all the explanations yet advanced as to the cause and nature of cancer; there is proof that cancer cells have not reverted to an embryonic undifferentiated state, and that the ceaseless growth of cancer cells does not resemble the intermittent growth of reproductive tissue. He closes with a serious appeal for co-ordinated investigation.

In contrast with Bashford's iconoclastic criticism, Butlin's Bradshaw lecture (*British Medical Journal*, December 16th, 1905) appears singularly fanciful. He sets himself to argue that carcinoma is a parasitic disease, the cancer-cell being itself the parasite; or more fully that the carcinoma cell is an independent organism, like many a protozoon; that it lives a life which is wholly independent and proper to itself; and that it lives as a parasite in the body of a host. To support this doctrine it is necessary in the first place to combat the generally received opinion of the epithelial origin of the cancer cells, and Butlin remarks that this origin has never been actually demonstrated. This he "illustrates" by certain figures which are either meaningless or have a misleading suggestion. The question next arises, whether on this hypothesis the parasite is introduced from without, or is formed within the body of the host. In opposition to Hauser, who has maintained the latter hypothesis, Butlin inclines to the former.

R.

Typhoid Bacilli in Sputum.—Rau (*Zeits. f. Hukl.* Bd. 25. S. 385) reports a case of pneumo-typhoid, in which the diagnosis was made by the finding of typhoid bacilli in the expectoration. No other bacterial excitant of the pneumonia could be detected. No intestinal symptoms were present, but the general course of the case was identical with that of ordinary typhoid.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynæcological and Obstetrical Literature."
- (4) "The Recent Literature of Anatomy, Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

THE PURE BRANDY CONTROVERSY.

Two correspondents, who were recently called on to give evidence in an adulteration case, have asked us to define what is pure brandy. Unfortunately the "British Pharmacopoeia" omits all mention of tests, which is probably due to the fact that when published (1893) the analysis of brandy had not received so much attention. The following, however, may be taken as the standard:—"An alcoholic liquid obtained by the distillation of the fermented unmodified juice of fresh grapes, and at least four years old." It must contain between 36 and 47 per cent of alcohol by weight, and the total solids are to be under 15 grammes per c.c.; and a limit of acidity is laid down, i.e. 100 c.c. shall not require more than 1 c.c. of normal KHO to make it distinctly alkaline to litmus.

DEUS INCUBAT ANGI.

Probably few of our readers know the meaning of the words which form the St. George's Hospital motto, "Deus incubat angul." Among the most original interpretations were, "The God incubates snakes," "The God is laying it into the snake," and last, but not least, "God hammers it in with angulak!" The words come from Statius' "Sylvarum," book III., story iv., p. 369 of vol. I. in the Delphin edition, published by Valpy in 1824. The passage is as follows:—

"Dicitur, Idalios Erycis de vertice luco
Dum petit, et molles agit Venu aurea cygnos,
Nergameas intrasse domos ubi maximus aegris
Auxilliarum adest, et festinantia sistens
Fata, salutifero mitis deus incubat angul."

Literally, the "God leans upon the serpent"—an allusion to the snake on the staff of *Asclepius*.—*St. George's Hospital Gazette.*

MARTIN, C.—A somewhat similar point was mentioned by a witness in a recent lawsuit. A lady wished to be reacquainted on her back. Although not in itself evidence of insanity, so unusual a desire had a corroborative value when taken with other evidence of eccentricities.

LIFE SPRINGS FROM DEATH.

None can deny the fact that die we must,
Our bodies sink into the grave and turn to dust;
Nature digests the morbid-mass, and in exchange
Gives fruit, and flowers, and grass, to arrange the balance just!
—A.D.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 24th.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Dr. J. Nisbet: The Planting of Waste Lands for Profit.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Mr. J. Hutchinson: Reminiscences of the Hunterian Society. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (23 Chancery Street, W.C.).—4 p.m. Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m. Lecture:—Dr. B. Abraham: The Treatment of Rheumatism.

THURSDAY, JANUARY 25th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—(11 Chandos Street, W.).—8 p.m. Card Specimens will be shown by Mr. A. S. Morton and Mr. G. Coats. 8.30 p.m. Papers:—Dr. A. M. Ramsay: The Treatment of Detachment of the Retina. Mr. S. Snell: (1) A Case of Thrombosis of the Cavernous Sinus; (2) A Case of Acute Oedema of the Eyelids. Dr. D. J. Wood: Case of Bilateral Hemianopsia.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Clinical Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Lecture:—Mrs. M. Scharlieb: The Differential Diagnosis of Abdominal Tumours.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m. Dr. M. Dockrell: Paratuberculides (due to Tuberculous Toxins); I., Macular; II., Papular; III., Pustular; IV., Pigmentary. (Chesterfield Lecture.)

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (7 Fitzroy Square, W.).—5 p.m. Lecture:—Dr. J. E. Squire: Phthisis in Old Age. (Post-Graduate Course.)

FRIDAY, JANUARY 25th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by discussion. Patients will be in attendance from 8 to 9 p.m.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Dr. St. Clair Thomson: Clinique. (Throat.)

Vacancies.

- Bristol, City and County of.—Public Analyst. Salary £450 per annum. Applications to Edmund J. Taylor, Town Clerk, Council House, Bristol.
- Burton-on-Trent Infirmary.—House Surgeon. Salary £120 per annum, together with furnished rooms, board, coal, and light, free. Applications to the Hon. Secretary, Mr. John Wood, the Infirmary, Burton-on-Trent.
- Parish of Bermondsey.—District Medical Officer. Salary £125 per annum. Applications to the Clerk to the Guardians, 283, Tooley Street, S.E.
- West Ham Union.—Four District Medical Officers. Salaries £130 per annum. Applications to Fred. E. Hilleary, Clerk, Clerk's Office, Union Workhouse, Leytonstone, N.E.
- West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, washing, and attendance. Applications to the Medical Director.
- Willenden Urban District Council.—Male Assistant Medical Officer. Salary £125 per annum, with board, lodging, and washing. Applications to Stanley W. Ball, Clerk to the Council, Public Offices, Dyne Road, Kilburn, N.W.

Appointments.

- BOWEN, J. ARNOLD, L.D.S.R.C.S.E., Dental House Surgeon at Guy's Hospital.
- BURGESS, ARTHUR H., F.R.C.S. Eng., M.B., M.Sc. Viet. Honorary Assistant Surgeon to the Manchester Christie Hospital for Cancer.
- BURROWS, HAROLD, M.B., B.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Seaman's Hospital, Greenwich.
- DODD, STANLEY, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., Resident Medical Officer at the Chelsea Hospital for Women.
- GRAY, A. G., M.B., B.S. Aberd., Bacteriologist to the Hospital of St. John and St. Elizabeth, St. John's Wood, N.W.
- HAMILTON, ROBERT, J., F.R.C.S. Eng., Honorary Ophthalmic Surgeon to the Stanley Hospital, Liverpool.
- JUBA, ARCHIBALD, M.D. Glasg., Assistant Medical Electrician to the Glasgow Royal Infirmary.
- KERRAWALLA, M. P., M.D. Brux., Clinical Assistant at the Samaritan Hospital for Women.
- MCBRIDE, JOHN, L.D.S.R.C.S.E., Dental House Surgeon at Guy's Hospital.
- MERCINE, C. A., M.B. Lond., F.R.C.S. Eng., F.R.C.P. Lond., Physician for Mental Diseases at Charing Cross Hospital.
- SCOTT, CHARLES WALTER, M.B., C.M. Edin., M.E. C.S., L.R.C.P. Lond., Clinical Assistant to St. John's Hospital for Diseases of the Skin, Leicester Square.
- TRELLING, W. H., MAXWELL, M.D., B.S. Lond., M.R.C.P., Honorary Physician to the Meanwood Convalescent Home for Children.

Births.

- CHAPPEL.—On Jan. 20th, at Lansdowne House, Tottenham, the wife of George P. Chappel, M.D., of a son.
- MORGAN.—On Jan. 19th, at Westcliff-on-Sea, the wife of W. Harmon Morgan, M.R.C.S., L.R.C.P. Lond., of a daughter.
- WATSON.—On Jan. 16th, at 5, Mount Ephraim Road, Tunbridge Wells, the wife of Charles R. Watson, M.D. Brux., M.R.C.S., L.R.C.P., of a son.

Marriages.

- EMERSON-TAIT.—On Jan. 16th, at St. Mary's, Castlegate, York, Lieutenant-Colonel I. Bomford Emerson, R.A.M.C., eldest son of the late John Emerson, of Deer Park, King's County, to Alice Emily, youngest daughter of the late Sir Peter Tait, D. L., J.P.
- FAIRBROTHER-HUGHES.—On Jan. 19th, at the Parish Church, Conway, Percy T. Fairbrother, third son of the late Henry Fairbrother, of "Holmea," Altrincham, to K. Winifred Hughes, widow of the late Captain M. L. Hughes, R.A.M.C., and daughter of Henry Simpson, M.D., of Glas Morfa, Conway.

Deaths.

- DE FARECK.—On Jan. 19th, at his residence, in London, William Frederick de Fareck, M.D., M.R.C.S. Eng., retired Surgeon-General Indian Medical Service.
- HILL.—On Jan. 19th, at 8 Churchfield Road, Ealing, David, third son of the late Andrew Hill, M.D., Cupar, Fife, aged 48.
- MALLAM.—On Jan. 19th, at 91, High Street, Oxford, suddenly, after a short illness, Henry Parr Mallam, M.R.C.S.
- SARELL.—On Jan. 15th, at 5 Sunderland Terrace, London, Fanny, daughter of the late Richard Sarell, M.D., M.R.C.P., of Constantinople.

The Medical Press and Circular.

Published every Wednesday morning. Price 5d. Post free, 5 1/2d.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 31s. per annum, post free, if paid in advance, or 32s. 6d. credit rate.

ADVERTISEMENTS.

FOR ONE INSERTION.—Whole Page, 25 0s. 6d.; Half Page, 12 10s. 6d.; Quarter Page, 6 5s. 6d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher. Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXII.

WEDNESDAY, JANUARY 31, 1906.

No. 5.

NOTES AND COMMENTS.

A Medical Man as Will Maker.

THE unbusinesslike ways of medical men are proverbial. The systematic tabulation and orderly conduct of documents and accounts are simply abhorrent to the average man of medicine. Indeed, nothing could be more remarkable than the contrast between his laxity in such matters and the accurate tenacity with which he usually controls his professional pursuits. An amusing instance of an Irish graduate's will came before the law courts last week. Genial, popular and the friend of everybody, this unbusinesslike gentleman was one day brought home in an injured condition after a carriage accident. Some mention was made as to his not having made a will, and he scrawled a few testamentary lines across an envelope, his signature to which was witnessed by a servant. That curious document has been upheld in the probate court, and the widow has inherited upon the strength of this truly Milesian will.

Not so Shallow After All.

A THOUSAND anecdotes might be recalled showing the want of business aptitude on the part of members of the medical profession. For all that, the defect is due to lack of special training rather than to any intellectual narrowing. In matters of organisation medical men, as a rule, display great prudence and fixity of purpose. Hardly any of the enterprises for self-protection and self-advancement have failed to become prosperous. We are still waiting, however, the crowning effort of professional combination which will give to us a really representative general medical council, control of our corporations, compulsory registration, a one-portal system of qualification, reformed Medical Acts, and other advances towards the medical millenium.

Mr. Troutbeck on the Coroner's Court.

THE Westminster Coroner, Mr. John Troutbeck, has been unburdening his mind to an interviewer of the *Daily Mirror*. From the published report of his utterances on that occasion we gather that he is in favour of sweeping reforms in the procedure of the Coroner's Court. So important are his remarks that we purpose dealing with them at length in our next issue. Meanwhile, it will be sufficient to state that they hinge more or less upon the assumption that every coroner should be a lawyer with the services of a skilled pathologist at his command. It is to be

regretted that the holder of a prominent public office should resort to so undignified a method of defence—for that is what the above-mentioned interview amounts to—in answer to attacks that have been weighty, well-sustained, multitudinous, and delivered in the full light of day.

Mr. Troutbeck's Trembling Hands.

THE Westminster Coroner has an unhappy gift for stirring up the waters of strife. He has done more towards the ultimate abolition of the ancient office of coroner than can be undone in a generation. He has embittered the medical profession, and embroiled them in a needless fashion with the London County Council. He has roused the British Medical Association, the defence societies, and the medical journals, while the whole medical profession, with the exception of Dr. Freyberger and one or two medical faddists on the County Council, are up in arms against his arbitrary and injurious methods. The fact seems to be that Mr. Troutbeck is so imbued with a profound distrust of his own ability to weigh ordinary medical evidence, that his heart yearns for the support of a so-called "expert." Why not adopt the simpler expedient of putting a well-trained medical man into the position now administered so unhappily by his trembling hands?

The Central Midwives' Board Again.

ONCE more the Central Midwives' Board has rescinded its previous resolutions in order to permit facilities to certain nurses, facilities which are contrary to the regulations of the Board. As will be seen elsewhere in our columns, on November 23rd the Board refused to grant an extension of time for signing schedules in the case of nurses belonging to the Cheltenham Nursing District Association, yet on January 25th, this resolution was rescinded and the extension granted. We think that the motion to rescind was proposed by the same lady who strenuously resisted all attempts to treat the Belfast Maternity Hospital with justice, and who also opposed the claims of the Rotunda Hospital. In spite of the protestations of the President and Dr. Dakin, the motion was carried. Dr. Dakin is a newly elected member of the Board and though this procedure must have opened his eyes to its manner of doing business, it will be some time before he can accustom himself to the entire absence of method and, indeed, in many cases, of legality in its procedure.

Rumoured Awakening of Army Medical Service. THE example of Japan in excluding enteric fever from its recent war operations appears to have stimulated—more or less—our own military authorities. It is rumoured at Aldershot that a school of hygiene is to be established there for the instruction not only of the R.A.M.C., but also of regimental officers. Well may officers of the old school rub their eyes and wonder what next is going to happen in the Service. The South African war, with its terrible mortality from enteric fever, shows the lamentable backward state of British camp and hospital hygiene. The Japanese have since proved that by ordinary scientific precautions preventable disease can be practically excluded from an army in the field. If British troops were sent out on a campaign tomorrow they would probably be not a whit better guarded against camp infection than they were in the South African campaign. After all, the re-organisation of the R.A.M.C. is only one of many military reforms that are urgently needed. Lastly, it is well to bear in mind that the War Office moves slowly in such matters, and that the school of hygiene is at present founded simply on rumour.

LEADING ARTICLE.

THE ORGANISM OF GENERAL PARALYSIS.

It is hardly possible for the man of moderate imagination to forecast the future progress of bacteriology. Even now, in its comparative youth, that ancillary science has simply revolutionised the practice of surgery, physic, public health, and other associated branches of medical work. Within the past nine months the elusive organism of syphilis has been almost certainly identified, although the chain of logical demonstration has not been yet absolutely linked together. The next step, supposing that the pathogenic nature of the *Spirochete pallida* to be established, will possibly be to show its relation to nerve syphilis, which is now known to us as an inveterate and progressive result in some cases of infection. The conclusion that locomotor ataxy is almost invariably the outcome of preceding syphilis has been established by methods of inference less direct than the detection of a constantly present specific organism in the affected areas of the spinal cord. Another disease of the nervous system, general paralysis of the insane, has also been ascribed to syphilis. It must be confessed, however, that hitherto the etiology of that mysterious and fatal malady has been among the obscurest problems of medicine. The possibility of microbial invasion is certainly suggested by many characteristics of the complaint. Some investigations by Dr. Ford Robertson, recently communicated to the Royal College of Surgeons of Edinburgh, cannot fail to draw universal atten-

tion to this peculiar form of associated progressive dementia and palsy. It appears that during the last six years a special investigation into the subject has been carried on in the laboratory of the Scottish Asylum, and at the Royal Edinburgh Asylum. Without being in possession of the full statement it may be briefly said that the results of these researches tend to show that general paralysis is dependent upon a bacterial toxæmia, and that the point of entry of the pathogenic organism into the system is usually through the alimentary canal. Dr. Robertson has found a micro-organism closely resembling that of diphtheria constantly present in the alimentary or respiratory tracts in cases of general paralysis. This organism has been detected in the fresh blood, in the cerebro-spinal fluid, and in the walls of the cerebral vessels. The bacilli were rarely capable of staining in the ordinary way, but cultures had been obtained from the brain in nine out of twenty-three cases of the disease in question. Dr. Robertson also made the statement that he and Dr. M'Rae were now able to bring forward evidence to show that general paralysis and the allied pathological condition, *tabes dorsalis*, were as specific in their causation as tuberculosis, enteric fever, diphtheria, and other well-known definite pathogenic infections. Other investigators have been at work on the same lines as regards the relation of diphtheroid organisms to general paralysis. The central fact of Dr. Robertson's announcement is the identification of the bacillus in the blood, the cerebro-spinal fluid, and the cerebral arteries. The confirmation or otherwise of his observations will be awaited with profound interest by medical men throughout the world, not to mention the large and increasing section of the outside community that takes an intelligent interest in the progress of medical science. The general consideration of this reported discovery leads inevitably to the regret that we have no great State-supported laboratories where these things might be investigated. As a mere commercial investment the cost of a great national organisation of the kind would soon be more than amply repaid, for there can be no greater economic saving to a community than that which follows the prevention of disease. Indeed, it says much for the unselfishness and the patient persistence of our great pioneers in scientific medical work that their achievements have been as a rule brought about with scanty means and by self-sacrificing toil. Their reward has been for the most part the consciousness of having left a rich heritage of knowledge to their own and to coming generations. Whether the news of the discovery of the specific organism of general paralysis be well founded or otherwise, it deserves authoritative examination by the State, backed with all the expert knowledge and special resources that can be supplied by the national exchequer. Failing that, we have no doubt the question—like many other great scientific problems—will be settled in the laboratories of private workers.

NOTES ON CURRENT TOPICS.

"Safe" Watercress.

THE repeated exposure of polluted watercress beds as a cause of enteric fever has naturally damaged the market for that particular greenstuff. The fact is that watercress farms ought to be registered and kept under strict sanitary supervision. It must be remembered, however, that they are often fed from streams and rivers that, hopelessly contaminated with sewage as they are, nevertheless supply drinking water to whole districts. Apart from that general consideration, there is often serious and open sewage pollution of the watercress beds themselves. We note with some trepidation an attempt on the part of certain public newspapers to restore confidence to the mind of the watercress consumer. The plan is specious, but woe to the luckless citizen who listens to the voice of the siren! The statement is to the effect that watercress is safe during the winter months, and that the only time when any danger of infection exists is during the summer and autumn. As a matter of fact, typhoid fever is always with us, and may spread by way of cesspools and drains in the winter as well as in the summer. Besides, there are many other disease organisms injurious to man contained in sewage. Our first and last words are that nothing can render watercress safe except the absolute purity of the beds from harmful germs. This latter can be secured only by official sanitary supervision and control. The sooner the man in the street recognises this, and demands a short Act of Parliament to keep his watercress sweet, the better for all concerned, whether growers, sellers, consumers, or sanitary authorities.

A Lawyer as Aural Specialist.

UNDER the heading, "A Lawyer Among the Quacks," our contemporary, *Truth*, relates a remarkable story. It appears that during the past few months, a new "cure" for deafness has been extensively advertised under the title of "Aug. Royel, Ltd." The originator and the chief, if not the only director, according to the journalistic authority above mentioned, is a Mr. H. W. Clarkson, a partner in a firm of London solicitors. The idea of starting an independent trade venture in deafness appears to have arisen from the fact that the firm in question acted as legal advisers to the notorious Drouet Institute. The stock in trade appears to have been an electric battery and a supply of pseudo-scientific pamphlets and other literature. The directorate apparently consisted of Clarkson and a commercial traveller, the latter of whom was eventually ejected after various legal actions commencing with a charge of embezzlement. The case is worthy of the attention of the Incorporated Law Society, for it may be pretty safely predicted of any advertised cure of deafness that it is a sheer, unadulterated fraud upon the public. The medical profession should be much indebted to *Truth* for discharging defence functions

on its behalf that would more appropriately appertain to our own General Medical Council.

Medical Man sued for Mistaken Diagnosis.

THE diagnosis of enteric fever, as every medical practitioner realises, is at times surrounded with insurmountable doubt and difficulty. Indeed, there is little reason to doubt that a certain percentage of cases of the "ambulant" variety run their course unrecognised. The sympathy of reasonable persons, therefore, must be with any medical man who pronounces an attack to be typhoid fever, whereas it is in reality some other serious illness. Last week a Brixton practitioner was called upon to defend an action for damages brought on behalf of a patient who had been certified as suffering from enteric fever and taken to an infectious hospital. The grounds for alleged damages appear to have been detention for seventeen days and injury to some goods in the process of "disinfection." For the latter, however, the local sanitary authorities were surely responsible. The judge very properly remarked that the action should never have been brought, and dismissed the suit with costs against plaintiff. Were any other result possible under such circumstances the conditions of medical practice would become intolerable. In any case the medical man who suspects enteric fever will do well to err on the safe side and treat the patient for that malady. To make the opposite error is to court speedy and irretrievable disaster.

A Medical Executioner.

AMERICA is recognised as the world's great birthplace of sensations. It must be confessed, however, that the public confession of a medical man that he has deliberately taken a patient's life in order to put her out of suffering—to us what is usually regarded by Britishers as pure Yankee vernacular—"caps creation." Yet the news comes with all the smoothness and circumstance of a concise report of a thing that has happened, although at the same time our readers will do well to keep at hand the grain of salt needed for most of the dishes of yellow journalism. Dr. Kempster, so runs the story, "one of America's most famous specialists in mental diseases," gave an overdose of morphia to a patient, the wife of a colonel. The unhappy lady was suffering terrible pain from severe burns, and had attempted suicide. There was no prospect of her recovery, so he ordered a local practitioner to fill a syringe with morphia, which he injected. An analysis of this case suggests that the fact of a medical man committing such an act wilfully is equalled only by his subsequently proclaiming it to the world. From a philosophical point of view, there is much to be said as to the justifiability, or at any rate the expediency, of destroying the lives of imbeciles, insane persons and persons smitten with mortal disease. There have always been two primary difficulties in the way: First, who is to decree the death, and, secondly, who is to carry out the sentence? Society would certainly not

permit the word of a single medical man to settle the fate of a fellow creature, nor is it likely that he would be an ideal executioner. However, the world travels fast nowadays, and it is well to bear in mind that Dr. Kempster's confession was called forth by a Bill now before the Ohio legislature to empower medical men to take the lives of incurables.

Abortionists' Methods.

THE way of the abortionist in this country is happily surrounded with so many difficulties that individual profits in this line of business are hardly sufficient to attract many competitors for favour, and the newspapers which stick at little in the way of advertisement do not lend their columns to further this crime. In America things seem to be different, or were so till an association was formed for the purpose of prosecuting people who lived by practising the procreation of abortion. To what length these anti-social pests had gone in seeking for business before the crusade was entered upon is shown by a circumstance that was brought to light at the trial of a certain Dr. Roberts, *alias* Hunt, of Boston. It appears that this scoundrel, who claimed to be a medical graduate of Edinburgh, had the impertinence to circularise the members of the profession at Philadelphia last summer by letter, pointing out that whereas many patients doubtless consulted doctors for the purpose of having an abortion procured, yet from the "specially delicate" nature of the case many men preferred not to "handle" them themselves, and that "family patronage" was thereby lost. Moreover, this tender-hearted philanthropist continued, the patients were thus driven "into the hands of quacks and irresponsible charlatans by which the city is pestered. You are well aware that this line of practice is too delicate in nature and too often involves risk of human life to be undertaken by any but one of undoubted qualifications and equipment." To the English mind it is amazing that any man—lay or medical—could have had the consummate impudence to write thus openly to the profession in a large civilised city, seeking their patronage for his trade; indeed, it is barely credible. The crusade against these criminals has begun none too soon. It is satisfactory to be able to record that Dr. Roberts, *alias* Hunt, is now undergoing six years imprisonment, along with several others of his peculiar kidney.

Football.

WE recently took occasion to call attention to the dangerous character the game of football was assuming in America, and at the same time expressed a wish that our players would not follow their lead in the development of the game. We have now before us the report of Drs. Nichols and Homer Smith, surgeon and assistant surgeon respectively to the Howard University football "squad" for 1905. It appears that it is necessary to have one of these gentlemen on duty not only

during the time when matches are played, but also during practice. In fact, they state themselves that the proportion of injuries sustained in matches and in practice is much the same. The report is enough to startle any English footballer. From it we learn that about 150 men passed through the "squad," but most of these did not remain in it long, and that seventy would constitute the real playing strength. Among these no less than 145 injuries of a character to prevent a player continuing to play were received during 1905. There were twenty-seven fractures of one kind and another, and eighteen dislocations, even if we do not reckon ten dislocations of the semilunar cartilages of the knee-joint that took place. One case of middle meningeal hæmorrhage occurred, and one of fracture-dislocation of the second cervical vertebræ are recorded, but though it is not specifically stated whether the patients recovered, the fair inference is that they did not. All the injuries detailed are severe, some being extensive contusions and bad sprains, others ruptured muscles and wounds. The medical corps includes a trained masseur, who seems to have been kept pretty busy, and surgical apparatus of all sorts was ready to hand during all games. We are not ourselves inclined to criticise the authors' contention that "the percentage of injury is too great for any mere sport," beyond saying that if they had said that the game had degenerated into a cross between a bull-fight and a gladiator-show we should have found even less reason to quarrel with their assertion.

The Universal Pill.

IN the course of recent electoral amenities, Mr. John Burns made fun of Mr. Chamberlain's policy by describing it as a "Morrison Pill." Since the days of Morrison and Carlyle many a universal pill has arisen and brought affluence to its proprietor, but it is interesting to notice that the ingredients of them are substantially the same. The basis of all—or practically all—the liver pills, head-ache pills, back-ache pills, and fancy pills for foolish folk is aloes; probably on account of its cheapness and convenience. Morrison's pill, we learn, was a compound of aloes, jalap, extract of colocynth, gamboge, rhubarb, and myrrh, surely as catholic and impartial a combination of laxatives as ever a "blunderbuss" prescriber conceived. We do not know if it enabled its enterprising proprietor to amass sufficient wealth to endow colleges for ladies and to found lunatic asylums, but it certainly permitted him to gain a handsome profit at the hands of his credulous customers, and to perpetuate the name of Morrison to generations unborn through the medium of "Past and Present." This mention by Mr. Burns of the famous quack and his claims only serves to remind one that fifty years more of experience and education have done nothing to awaken people to the fallacies of "Universal Pills," or to the lies of their proprietors.

The Profession and Alcohol.

THE *Medical Temperance Review*, in the first number of its ninth volume is very jubilant at the progress that has been made by the British Medical Temperance Association during the thirty years of its existence. The Association and its journal have every reason to congratulate themselves, for it is indisputable that the general opinion of the profession on the question of alcohol has undergone a striking change during that period, and it is probable that the Association itself has had some share in aiding the transformation. The establishment of the London Temperance Hospital in 1873 was a bold experiment in then-existing conditions, but though the Institution has gone through various vicissitudes, it has now established itself firmly as a well-equipped modern hospital, with a death-rate and cure-rate good enough to please its founders' hearts. As medical opinion with regard to the use of alcohol has become more moderate, so, too, if we mistake not, have the opinions of the bulk of scientific teetotallers, and it is possible that in the near future a *via media* may be established where all may meet on common ground. At present the *Temperance Review* holds out strongly for total abstinence as the only way by which the admitted curse of alcoholism may be banished from the community. That, we fear, is impracticable so far as the masses of men are concerned, at any rate, till education and culture are far wider spread than they are to-day. And at present the well-educated classes consider themselves able to judge how far they may take alcohol without exceeding the bounds of strict moderation, so that total abstinence becomes a matter for individual choice. But that any man is materially the worse for being a teetotaler, we fancy there would be but few medical men at the present day prepared to maintain.

Beri-beri in the Japanese Navy.

A SOMEWHAT remarkable observation has recently been made known with regard to beri-beri. Speaking before a New York Medical Society, Baron Takaki, Surgeon-General of the reserve of the Japanese Navy, stated that the introduction of a meat diet had practically stamped out beri-beri in the Navy. The significance of that fact becomes apparent when it is added that previously no less than 40 per cent. of the crews suffered from the disease. The average weight of the sailors, according to the same authority, had increased by eight pounds. The etiology of this peculiar form of peripheral neuritis has always been in doubt. Although it has often been ascribed to a diet deficient in nitrogenous food; the point has never been established. The possibility of so well-marked a nervous disease being amenable to diet opens up a great field in kindred affections. From many points of view the Japanese Navy experience in beri-beri appears to possess a potential value of a kind difficult adequately to estimate.

PERSONAL.

DR. W. OSLER will deliver the Harveian Oration of the London Royal College of Physicians on St. Luke's Day, October 18th, 1906.

THE Milroy Lectures of the same College will be delivered by Dr. W. H. Hamer in March; the subject being "Epidemic Disease in England; the evidence of variability and of persistency of type."

SEVERAL representatives of the Liverpool School of Tropical Medicine recently attended Bunbury Church at a memorial service and the unveiling of a stained glass window to the memory of Dr. J. Everett Dutton, who, it will be remembered, died whilst out in the Congo investigating sleeping sickness.

THE Metropolitan Branch of the Society of Medical Officers of Health held its jubilee dinner at the Holborn Restaurant last evening, under the presidency of Dr. John Priestley, medical officer of health for Lambeth.

AT the ordinary quarterly *comitia* of the Royal College of Physicians of London, held on Thursday, the following Fellows of the college were elected to fill vacancies in the council:—Dr. William Osler, Dr. H. R. Crocker, Dr. H. H. Tooth, and Dr. T. D. Acland.

H.I.H. the German Emperor has conferred the Crown Order of the Third Class on Mr. Charles A. Ballance, F.R.C.S.

DR. BEEBE, of the Cornell Medical School, claims to have manufactured from diseased human thyroid glands a serum that will cure exophthalmic goitre.

PRINCE LOUIS OF BAVARIA, a skilled surgeon, has performed during the last fortnight several operations in Madrid, where he has been staying for the marriage of his son.

MISS ANNA HALL has drafted a Bill recently introduced into the Ohio Legislature authorising physicians in certain circumstances to put invalids to death.

DR. ERNEST OTT, who was his Majesty's medical attendant during his stay at Marienbad last year, had the honour of being invited to dinner at Windsor Castle on Saturday last by the King and Queen.

WE have to record two important Continental appointments which were made last week—the chair of the late Prof. Nothnagel, in Vienna University, has been filled by Prof. van Noorden of Frankfort, and Prof. von Bergmann, who, it will be remembered, was called in with the late Sir Morell Mackenzie in the Emperor Frederick's fatal illness, has been given a seat in the German House of Lords by the Kaiser.

THE GENERAL ELECTION.—The following members of the medical profession have been returned to Parliament since our last issue: The Rt. Hon. John Morley, Dr. Cooper, Bermondsey; Sir W. J. Collins Paddington; Mr. R. Ambrose, West Mayo; Mr. R. J. Price, re-elected for East Norfolk; Dr. A. R. Rainy, for the Kilmarnock Burghs; Sir G. S. Robertson, K.C.S.I., Bradford (Central), and Dr. V. H. Rutherford, the Brentford Division of Middlesex. Amongst those who have lost their seats are Sir Michael Foster K.C.B., for London University, and Dr. C. F. Hutchinson for Rye.

THE Committee of the Bristol Royal Infirmary have unanimously elected Mr. Walker Hall, M.D., C.H.B., to the newly-formed post of pathologist, bacteriologists, and director of clinical laboratories.

A CLINICAL LECTURE

ON

RIGHT-SIDED PLEURISY IN THE SUBJECTS OF HEART DISEASE.

By Prof. LOUIS RENON, M.D., Physician to the Pitié Hospital, Paris.

(SPECIALLY REPORTED FOR THIS JOURNAL.)

THREE patients at present in my wards suggest to me as a subject for to-day's lecture the occurrence of right-sided pleurisy in persons suffering from heart disease, an affection which runs a peculiar course, and the diagnosis whereof is often a matter of some difficulty. This right-sided pleurisy is met with in the subjects of valvular disease as well as in the victims of cardio-vascular lesions.

Allow me to point out to you first of all the differences that present themselves between valvular and cardio-vascular affections, and I hope to make it clear that the two states are very unlike each other. In valvular disease the lesion starts in the valve and ends in the myocardium; after the initial rheumatic endocarditis comes valvular deformation, with its murmurs; more or less prolonged period of compensation, then we come to the periods of hyposystole and asystole, with œdema of the limbs, passive congestion of the lungs and the cardiac liver. In cardio-vascular affections the picture is quite different. The patients have never had rheumatism, instead of which we discover that they have suffered from gout, alcoholism, over-indulgence in tobacco—this great excitant of cardiac spasm, lead poisoning, excessive indulgence in meat or chlorides, depressing emotions, excessive intellectual work, and senile degeneration. The cardiac muscle is involved in its arterial system, and the patient begins with myocarditis, to finish by valvular lesions. You may meet with transitory or permanent murmurs; these are not the murmurs of valvular deformation, but are most frequently due to functional inadequacy, consequent upon dilatation of the heart cavities and orifices. Asystole in these cases is not, as in the other cases, a terminal condition, the natural end, so to speak, of the malady; it is, on the contrary, an acute state, a hypertensive complication arising, it may be, from a slight cause—digestive disturbance, overwork, a passing emotion, an infection, dietetic errors or an excessively salted alimentation or an intercurrent intoxication.

Pleurisy occurs more frequently in connection with arterial cardiopathies than with valvular disease. The pleurisy is usually on the right, indeed, it may be laid down as a general rule that pleurisy in a cardiac subject is almost always on the right. The three following cases afford an additional proof of this right-sided tendency. When I have briefly described them we will discuss the clinical aspects of these effusions.

My first case is that of a woman, æt. 40, who came into the service last December, a prey to violent dyspnoea and presenting marked œdema of the lower limbs and of the abdominal parietes. The symptoms had started three years before by dyspnoea following an effort and had been steadily getting worse for two months past. The only point of interest in her personal history was a slight tendency to ethylism. On examination the heart-beat was heard to be irregular and rapid, and the sounds were muffled and, so to speak, lacked precision. Percussion caused too much pain for us to be able to establish the outline of the organ. The pulse was small, rapid—120 per minute. The lungs were the seat of coarse, sibilant, sonorous râles, and there were unmistakable signs of pleural effusion at the right base; absolute dulness, entire absence of vibrations, absence of breath sounds, without ægophony and without aphonic pectoriloquy. The urine was scanty, very dark and loaded with albumin. The liver was big and painful on pressure, its lower margin extending three fingers' breadth below the false ribs.

In presence of all these symptoms I diagnosed asystole with right pleural effusion, reserving a decision as to the exact nature of the heart lesion for the present, since it could not be determined. I applied wet cups over the cardiac area and ordered a mild saline purgative, a milk diet and fifteen drops of a 1-000 solution of crystallised digitaline. On the following day the dyspnoea had greatly diminished, the pulse was slower and on auscultation I was able to make out two murmurs over the aortic area, one systolic and the other diastolic. I substituted theobromine (25 grains in the twenty-four hours) for the digitaline. Cytological examination of the fluid showed it to contain numerous epithelial bunches, some red corpuscles and lymphocytes. During the next few days the patient's breathing was easier, diuresis was copious, the œdema diminished, and she was improving rapidly, when, on December 26th, in consequence of an imprudence, she became suddenly worse. The temperature rose, the left lung was congested, and the lower limbs again became œdematous. At the right base local fremitus was diminished and the vesicular murmur was abolished, but the supervention of fine friction râles justified the supposition that the pleural surfaces were in contact, and that there was no effusion. On January 2nd, 1905, the patient died suddenly in the act of sitting up in bed.

Post-mortem.—When the thorax was opened, a yellow liquid escaped in large quantities from the right pleural cavity. The right lung, pressed upwards and backwards, was flattened against the posterior wall of the thorax and all the liquid was contained between the base of the right lung and the greatly depressed diaphragm. The liver which had appeared to be greatly enlarged only weighed a little over two pounds. It was small and hard, and was evidently merely pressed down by the fluid and in no wise hypertrophied. The lungs were markedly congested. The enlarged heart weighed eighteen ounces. The edges of the aortic valves were indurated and thickened. The aorta was dilated at the arch and incrustated with atheromatous patches. The kidneys were cyanosed and the spleen was small and hard, and its consistency increased.

In this description I would call your attention to the existence of an aortitis, to the right pleurisy and to the sudden death of the patient, due apparently to the copious effusion which we thought had dried up. Remember also the small size of the liver which we took to be greatly enlarged when, as a matter of fact, it was merely pushed down by the liquid that had accumulated between the base of the lung and the upper surface of the diaphragm.

The second case is that of a man who is now in our wards for the third time. He is sixty-five years of age, and in the course of three years has been tapped thirteen times for right pleural effusion—the first in 1902, the last in March, 1904. Twelve punctures were performed in seven months, eight of which were done in four months. On eleven occasions the fluid was sero-fibrinous, and twice it was hæmorrhagic. It was cytologically examined on three occasions, a first time in December, 1903, when epithelial patches and a few lymphocytes were found, and on two other occasions when lymphocytes were also discovered in the hæmorrhagic liquid.

There are several points to be noted in the evolution of this recurring right-sided pleurisy. To begin with the effusion was not very abundant though the dyspnoea was intense, and on each occasion more fluid

was withdrawn than had been anticipated. With regard to the cause of the effusion the presence in the fluid of epithelial plaques and lymphocytes suggested pleurisy of mechanical or tuberculous origin. As no tubercle bacilli were found in the expectoration, though repeatedly examined, and as the patient was suffering from arterio-sclerosis we were fain to assume the cause of the pleurisy to be cardiac.

The arrhythmia, the tachycardia, the heightened arterial tension, the presence of a systolic murmur, essentially temporary and variable, as it always is in this affection, all pleaded in favour of this view. Moreover, there was no history of rheumatism and when the patient again applied to us it was on account of intense dyspnoea accompanied by frothy expectoration similar to that of the cardio-renal patients who, in the course of hypertension, develop the main symptoms of acute pulmonary oedema.

The third case is that of a woman, also suffering from cardio-sclerosis, who was punctured a few days since in a very unusual spot, *viz.*—in the third right intercostal space in front on the nipple line. The liver dulness appeared to be enormous, and seemed to reach above to the second rib. Taught by the experience of the previous cases, I declined to adopt the view of the liver being so large, and I mentioned to you that we probably had to do with a right-sided pleurisy of which there was no outward manifestation. Several of you appeared sceptical as to this, but you had to give way when an exploratory puncture into the dull area gave issue to sero-fibrinous liquid. I will not dwell longer on this case, there being several other points to which I must call your attention.

These right-sided pleurisies in cardiac patients are really pleurisies and not hydrothorax. The pleural inflammation is unilateral, it is accompanied by fibrinous exudation and false membranes, and, lastly, it presents a special cytological formula. The fluid is purulent, hæmorrhagic or sero-fibrinous. These cardiac pleurisies vary as to their seat and the symptoms are modified accordingly. The pleurisy may involve the general pleural cavity or it may be diaphragmatic, mediastinal or encysted. In spite of the differences of symptomatology due to the difference in position, these pleurisies have certain features in common—*viz.*, a slow insidious onset, a certain latency of the symptoms, always masked by the concomitant cardiac dyspnoea, and the quantity of fluid is always superior to that estimated prior to making the puncture. These cases present the signs of ordinary pleural effusions, which I need not describe. But, as in my first two cases, we must note the possibility of recurrence of the effusion and considerable displacement of the liver which may lead us to diagnose hypertrophy.

Right diaphragmatic pleurisy is much more interesting. My third patient gives a very good idea of the curiously special aspect of these pleurisies. The history of this patient is in all points similar to the three cases which I discussed here in 1903.* I summarised the clinical features of this type of pleurisy in the "Archives generales de Medicine" (1903, p. 1508), where I laid it down as follows:—Always before we look out for pulmonary infarct in patients with heart disease, whatever its nature, whether valvular or arterial; these cases are capable of taking you off your guard, as you will see. We will suppose that you are treating a patient suffering, say, from mitral stenosis. In addition to the ordinary signs of this particular heart lesion, you find passive congestion at both bases. Under the influence of the usual treatment, the dyspnoea diminishes, the general state improves, and the end of the attack seems within measurable distance, when one day you are summoned on account of a sudden violent pain in one or other part of the right lung. On examination, you find the signs of pulmonary infarct: dulness, fine sub-crepitant rales and a souffle; a day or two later the appearance of characteristic bloody sputum confirms the diagnosis.

So far so good; you dry or wet cup, you do your best to calm the distressing oppression and you hope that in a short time the small infarct will be completely absorbed. But if it happens to be situated just beneath the pleura, and if, owing to the special septic condition of the embolised territory, it determines a sero-fibrinous effusion your forecast will not be realised. The effusion will take place, and the liquid will, as a rule, collect in the general pleural cavity, but sometimes it becomes encysted, loculated, or forms in the mediastinum. Lastly, it may hide itself between the base of the right lung and the diaphragm—an odd, unfortunate situation which is pretty sure to escape your vigilance, unless you happen to be acquainted with it. We are now far from the original pulmonary infarct that seemed so simple a matter.

This diaphragmatic, right-sided pleurisy runs a latent course. The only sign is the dyspnoic pain of the infarct. None of the ordinary signs of pleurisy are present, no dulness or only the partial dulness of the congested bases, vocal fremitus is preserved, and on auscultation we hear merely some fine sub-crepitant rales. Sometimes the signs leave us in doubt and to clear up the diagnosis we puncture in the two last costal interspaces in the axillary line, and we find nothing.

In the axilla, in front, we may, however, discover something unusual. The liver seems suddenly to become enlarged, the liver dulness may reach almost from the clavicle down into the abdomen, and the margin can be felt below the false ribs for two or three fingers' breadth. The only explanation that suggests itself is a large cardiac liver, and we turn our attention to the heart lesion, enjoining perfect repose, milk diet, purgations and cardiac drugs in order to reduce the size of the liver, and all at once the patient dies, an unhappy experience which was mine in the first of the three cases I have related to you.

Post-mortem you find three pints of fluid in the right pleura, hidden away underneath the base of the lung, between it and the diaphragm. A tolerably thick layer of lung tissue reaches backwards, covering the costal wall right to the very bottom of the costo-diaphragmatic sinus. This explains why we could not detect the pleurisy, although we searched for it daily and even resorted to an exploratory puncture. The fluid was only in contact with the diaphragm, and the base of the lung. Another surprise is sprung on us, the liver that we had taken to be immensely enlarged turns out to be of normal dimensions; it has merely been pushed down by the layer of fluid on the upper surface of the diaphragm, and the dulness that we found in front during life was dependent upon two different conditions: above there was the liquid dulness, and below the liver dulness. Our error has been threefold; we were wrong as to diagnosis, as to prognosis and as to treatment.

If you are acquainted with this clinical type, the diagnosis is fairly easy, and in the two last cases I was able to make out the actual condition of things, warned as I had been by my previous mistakes. Following an infarct of the right lung, I found a few days later, extensive dulness in the axilla in front with displacement downwards of the liver. There was an absence of thoracic vibrations and of vesicular murmur, and that placed me on my guard. I made an exploratory puncture in the fourth right intercostal space in the nipple line, and I withdrew some sero-fibrinous fluid. A puncture behind, in the ordinary spot, gave no result, in consequence of the thickness of the layer of lung tissue lying against the thoracic wall, it was only with a very long needle that I should have had a chance of coming upon the fluid after piercing first the thoracic wall and then the layer of lung in contact therewith.

I have nothing to add to this description; the various observations that I have since made only confirm what I have said.

The mediastinal pleurisy of cardiac patients presents the usual symptoms of mediastinal effusion.

* *Mémoire. 'La Pleurisie intestines-diaphragmatique des Cardiaques.'* Journ. des Praticiens, June 6th, 1903.

The mediastinal syndrome dominates the scene with its pressure phenomena. This form of pleurisy often ends in the formation of a serous or purulent collection.

Encysted pleurisy is rare in cardiac patients. The signs are extremely variable according to the particular part of the serous membrane where it happens to become encysted.

The pathogenesis of right pleurisy in cardiac patients is wholly dependent on sub-pleural pulmonary infarct, septic or not. In many cases the pulmonary apoplexy is obvious, a sharp pain followed by the appearance of bloody sputum precedes the effusion by a day or two. Sometimes the signs are less characteristic, the pain may be trifling, but the dyspnoea is well marked and the unexpected presence of some muco-purulent expectoration attracts the attention.

It follows that the diagnosis of this form of pleurisy is both easy and difficult, easy when it is situated in the general pleural cavity, although even then one is apt to be greatly deceived as to the quantity of the effusion. In all other cases it is difficult, especially in the mediastinal form, and in latent right supra-diaphragmatic pleurisy. I warn you to be on your guard in such cases when you find dulness in the axillary hollow or in the right sub-clavicular region. Hesitate to accept the hypothesis of a very large cardiac liver of which the upper limits are quite abnormal. I have explained to you that in such cases the liver is, as a rule, simply displaced and not hypertrophied. Make an exploratory puncture in the dull area and often, greatly to your surprise, you will strike fluid. If you puncture behind, in the ordinary spot, use a long needle for, you will have to pierce a layer of pulmonary tissue lying against the posterior thoracic wall. The cytological examination of the fluid, demonstrating the presence of endothelial plates with a few lymphocytes will confirm the nature of the effusion.

The prognosis in right-sided pleurisy in cardiac patients must be guarded. To begin with, these effusions, essentially latent, may easily be overlooked. Then, too, they are very apt to reform, and, lastly, they add another factor of oppression to a disease itself dyspnoic in character, and they may aggravate a condition already sufficiently precarious.

The treatment comprises two principal indications. The first is to evacuate the fluid as often as may be necessary; the second is to treat the original cardiac lesion in order to avert the further formation of infarcts, the commonest cause of these pleural complications.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of the journal. The lecture in next week's will be on "*Syphilitic Pseudo-General Paralysis*," by Hy. T. Bewlay, M.D., Dub., F.R.C.P., Physician to the Ad-*laide* Hospital, Dublin.

ORIGINAL PAPERS.

THE RELATION OF SPIROCHÆTA (SPIRONEMA) PALLIDA TO SYPHILIS.*

By THEODORE SHENNAN, M.D., F.R.C.S.

Senior Pathologist to the Edinburgh Royal Infirmary, Lecturer on Pathology and Bacteriology, School of Medicine, Royal College of Surgeons, Edinburgh.

That syphilis is due to a *contagium vivum* has long been believed. Even in the seventeenth century this was the view held by Kirscherius and David Abercromby, while in 1723 Deidier urged a similar hypothesis. In 1839, Donné described as the exciting agent a "*vibrio lineola*," while since his day a great number of micro-organisms had been isolated

and put forward as the causal agents of syphilis. None of these, however, had been proven to the satisfaction of other than the discoverers; among those which had had the greatest vogue were Lustgarten's bacillus (probably a *smegma* bacillus), and the organisms of Lostörfer, Winckler, Niessen, Schüller, and Siegel. The last-named had discovered an amoeba-like organism, to which he gave the name of *cytorrhyses luis*, and it was on the publication of this discovery that Schaudinn and Hoffmann were appointed by the Prussian Government to investigate the relation of the *cytorrhyses* to syphilis. In the investigation they discovered the *spirochæta pallida*, and their observations had been abundantly confirmed and amplified during the year which had elapsed since their first communication appeared. In and about venereal and other sores on the genitals one or more varieties of *spirochæta* are commonly found. One of these is merely saprophytic, and is also present in the mouth or other parts of the body. To it the name of *spirochæta refringens* is given. The *spirochæta pallida*, on the other hand, has so far only been detected in syphilitic lesions of the primary and secondary stage; it has been detected in hard sores, syphilitic bubos, mucous patches, and, though with greater difficulty, in the roseola and in the circulating blood. It has also been found fairly constantly in the viscera and the fluid from the bullæ of pemphigus of still-born syphilitic foetuses. An important point in connection with the organism is that it is most readily detected in the deeper parts of the lesion. The description of the *S. pallida*, as given by Schaudinn and modified by subsequent observers, is as follows: It is an extremely delicate organism from 7 to 14 μ in length, and consists of a series of deep, regular spirals from six to twenty in number, the average being eight to ten. Flagellæ have also been described, and so has a granule placed about one-third way along the organism. There is some doubt as to the existence of a vibratile membrane. The *spirochæta* can be seen in unstained and stained preparations; when alive it is motile, the movements being spiral, lashing, and backwards and forwards. The *spirochæta pallida* is believed to be related to the *trypanosomes*. The *spirochæta refringens* is saprophytic; its spirals are larger and less regular, and it is in every way a less delicate organism. The best stain for the two *spirochætae* is Giemsa's, by which *S. pallida* is tinted a delicate pink and *S. refringens* a deeper purple colour. This is the only differential stain known. In preparing films the important point is to get tissue juices and cells from the deeper parts of the lesions after scraping or thoroughly cleansing the surface. The juice of the bubos may be removed by a syringe, the glands being massaged the while. A few blood cells are not disadvantageous, as they assist focussing, and the *spirochætae* are often attached to them. Only fresh tissues should be used to obtain the organism. After six or eight hours none can be found in excised glands or sores—a point of some interest in connection with the short persistence of the syphilitic contagion about bodies. Films should be very thin, and fixed as soon as possible by alcohol or osmic acid. At least six should be examined before the organism was pronounced to be absent. *Spirochætae* intermediate in form and appearance were very commonly met with; for this reason it was necessary to be very careful in coming to a conclusion where *spirochætae* were present in great number, especially in preparations made from ulcerated lesions. As a rule only a few *spirochætae* were found in films made from deep parts. A further proof of the etiological character of the organism was found in the fact that Metchnikoff and Roux have detected it in the experimental lesions produced by inoculating chimpanzees, orang-outangs, macacus, and cynocephalus monkeys with syphilis. Dr. Shennan then enumerated the cases in which he had demonstrated the organism, and gave a statistical *resume* of the frequency with which it had been found by other observers. From this it appeared that it could be got in the great majority of primary and secondary syphilitic lesions, but not in the tertiary

* Abstract of paper read before the Edinburgh Medico-Chirurgical Society, January 17th, 1906.

stage. The only two instances of spirochætae in tertiary syphilis were really cases of late secondary. In one of his cases he had detected a peculiar flagellated body, of the nature of which it was impossible to be certain. Castellani and Wellmann had also found the *S. pallida* in yaws. Very many control observations made on ulcers of non-syphilitic nature, skin diseases, tumours of all kinds, &c., had failed to show the occurrence of *S. pallida* in lesions other than those of syphilis. The etiological relationship, however, could not as yet be regarded as settled, though there seemed a fair probability that it was the true cause of the disease. One of the difficulties was that there were so many forms intermediate between *S. pallida* and *S. refringens*. On the other hand, the fact that *S. pallida* was found chiefly in the deeper tissues, and particularly in the viscera of congenital syphilitic fetuses, was strongly in favour of its specific character and against its being a mere saprophyte.

A NEW METHOD OF SERUM THERAPY.

By D. M. PATON, L.R.C.P., L.R.C.S.ED., L.F.P.S. Glasgow.

FOR eight years the writer has been studying, clinically and experimentally, the use of serums exhibited by the mouth. During that time he has used over twenty million units of anti-diphtheritic serum (ADS.) and forty gallons of simple plasma of the horse, sheep, and ox. This article is a short statement of some of the results obtained, but the writer hopes shortly to put the whole work more fully before the profession in book form.

Among the clinical examples are some from the writer's own experience, as well as from others who have tested the treatment. The trouble has not been so much about the actual results as about a rational explanation of the phenomena observed. The theory which at present seems to most fully explain the results is indicated in the course of the article.

The anti-diphtheritic serums used have been supplied by Messrs. Parke, Davis and Co., who stock a low potency serum in 1 oz. bottles containing 6,000 units, enough for eight doses—1 oz. serum in aq. 4 oz.— $\frac{1}{2}$ oz. dose. They have supplied it to my order for years, and have called it "Paton's" serum. For chronic suppuration there is another serum with greater anti-proteolytic power. It has been called "Special," and the dose is the same as the other serum.

For acute conditions, 1 dr. of serum at once and every half-hour or hour for three or four doses, then every two or four hours as required. For less acute cases, 1 dr., four times a day, is generally sufficient.

I.—(a) *The Use of Simple Plasma by the Mouth in Function Deficient through Innutrition.*—The plasma is the food elaborated and fitted for direct tissue feeding and energising. In the animal its mission is to maintain nutrition and repair of tissue and enable function to be carried on in a state of normal efficiency. When given to a suitable patient by the mouth in doses of 1 dr., four times a day, it does the same work in the patient for which it was elaborated in the animal. The writer has seen scores of cases during the last two years, and has used about 40 gallons of the material in his work. A typical case on which to test the value of the plasma is that of a *post-partum* patient who is making a poor recovery, whose tissues are flabby and soft, who has little appetite or digestion, little energy or capacity for walking, probably some sub-involution and a deficiency in either quantity or quality of milk or possibly both. The use of plasma in 1 dr. doses four times a day has proved a sovereign remedy, leading to restoration of tissue tone, and renewing the lactation, so that it becomes what is normal for the patient in quantity and quality. The reaction which produces this effect is all the more marked if there is present the tuberculous diathesis, a fact which indicates the unique character of its action.

Not only is the milk restored, but preceding and accompanying it there is a restored appetite, digestion, and assimilation of food, a feeling of *bien-être*, and capacity to get about and do household duties and a freedom from the continuous feeling of weariness and exhaustion. When that is accomplished reduced doses will maintain what has been gained.

In anæmias alone, or in conjunction with ordinary treatment, in convalescence from disease or operation, in the very old and debilitated, and the very young, the oral use of plasma has the same effects as in the typical cases mentioned.

Now the albumin in $\frac{1}{2}$ oz. of plasma is quite incapable of any such result; even if it were all absorbed unchanged it never would produce a return of digestive function and all the other tissue vigour, and there must be something else in it to account for the results. There are evidently in the serum the elements which the animal has elaborated for the energising of the nerve centres which control the various tissues, and these, addressing themselves to the centres controlling the tissues requiring increased vigour, are able to produce results which are otherwise quite incapable of reasonable explanation. It is simply an increased tissue tone producing normal function and ceasing when normal conditions have been attained.

II. *Simple Plasma in Infection.*—The horse and sheep are resistant to tubercle, but, the initial resistance overcome, they deteriorate as fast as any other animal. Thus it is their initial defence which is their resistance to the infection. The ox has less initial resistance to tubercle, but, on the other hand, is extremely resistant to influenza.

In the treatment of over fifty cases of tubercle of all kinds, the oral use of the simple plasma of the horse and sheep has proved itself capable of transferring to the patient the resistance of the animal to the disease. That is, that the reaction which is seen in non-microbial cases, and which leads to restoration of tissue tone and normal function, is also obtained in the presence of the tuberculous infection where it is not mixed with other infections or is not of such an intensity as would inhibit the reaction in the animal itself. The horse and sheep are susceptible to catarrh and influenza, and the advent of these in a case which is doing well on plasma is seen at once by the inhibition of the reaction, exactly as it would happen in the horse or sheep. Thus we obtain the reaction in the presence of those infections to which the animal is more than usually refractory but in no others.

This action cannot be antitoxic for antitoxin is not absorbed by the stomach. The action on the tissue tone is such as can only be explained on the same grounds as the reaction in non-microbial cases, with the addition that the tissue tone which is produced is of such a character that it maintains the functions unimpaired in the presence of the infection and is by so much a resistance to the disease.

Cases have been treated privately in my own and other practices, in Echuca Sanatorium in Victoria, Stobhill Hospital, Glasgow, and in the Bridge of Weir Sanatorium Dispensary in Glasgow. The net results have been that more than 75 per cent. of the patients have shown the reaction. Their resistance to the disease has been materially increased, and their symptoms, appetite, cough, expectoration, general strength and frequently physical signs have all shown a marked improvement. A week's treatment is generally sufficient to tell whether the patient is going to obtain benefit or not.

If for nothing else, the use of plasma in this disease would justify itself by its action on those troublesome dyspeptic symptoms which are so frequently seen in tubercle. No case so far has failed to yield to the plasma, three tuberculous throats have all had their pain removed, bladder, surgical, and phthisis cases have all done well. It is not cure but it is an essential in the cure of the disease, for its action is the restoration of the tone of the tissues, the lowering of which was the

cause of the infection and subsequent deterioration of the patient.

Children do remarkably well, one who has had eight weeks' treatment being so much better in a colleague's practice that he examined her afresh to see if he had not made a mistake in diagnosis. Abdominal tubercle, unless in the last stages has shown itself amenable by the removal of pain, diarrhoea, &c., and the return of appetite, digestion, and increased vigour. The keynote for the use of plasma is lowered "tone" in the tissues, that intangible something which is nevertheless our defence against infection. Practically it means a lessened reaction which in turn prevents the tissue from procuring sufficient nutrition and its capacity for resistance is correspondingly lowered.

An interesting result was seen in some cases which had been treated with plasma with benefit and to which Jacob's sero-tuberculin was added hypodermically. As the dose of the tuberculin was increased the effect of the plasma gradually lessened and then ceased. It was clear that the one treatment was antagonising the other. The plasma was then withdrawn with the result that, although the tuberculin was given in doses of a half and a third of what was due, there followed in all the cases a marked reaction after the next dose of tuberculin. Some of the temperatures reached 104° and 105° , but all subsided, and with the reduced dose after that there was no undue reaction. The lessened tissue resistance was very evident in all the cases after the plasma was withdrawn, and with the reaction there was also a decided loss of weight.

III.—*Antidiphtheritic Serum in the Treatment of Septic Inflammation and Suppurations.*—The theory of the action of serum in the preceding paragraphs, as well as in the remainder of this article, may be summarised as follows:—

1. Every tissue has a capacity for nutrition and repair and maintenance of function.
2. This capacity becomes resistance to infection when it is capable of carrying on the function unimpaired in the presence of the infection.
3. The oral use of the plasma (normal) of an animal conveys to the patient the elements elaborated by the animal to produce in its tissues the reactions necessary for nutrition, repair and maintenance of normal function. And its oral exhibition produces in the patient the same reaction as in the animal.
4. When these normal reactions raise the tissue tone so that a natural refractoriness to any particular infection is produced in the animal the same result is produced in the patient by the oral use of the plasma of the animal. Such as the horse and sheep in tubercle and the ox in influenza.
5. Where an animal is artificially immunised to an infection, the elements in the serum producing the reaction for the nutrition, repair, and maintenance of function in the tissue pathologically affected by the toxic products of the organism used are all abnormally developed.
6. In antidiphtheritic serum the elements developed to maintain function unimpaired in the presence of the paralytic and muscle depressing and the proteolytic and albumose-forming elements in the toxic culture used in the production of immunity are available to meet the action of the streptococcus and staphylococcus on the same tissues.
7. The same tissue-restoring elements are available in traumatism or tissue damage from any non-microbial cause. Hence they are tissue restoring and maintaining elements and are not specific antitoxins.
8. The developed elements in antidiphtheritic serum are a muscle recuperative power to antagonise the muscle depressant and an antiproteolytic to meet the proteolytic action of the organism; also a hæmopoietic power leading to increased leucocyte production where required.

Antistreptococcal serum contains at least the first of these qualities.

That is, that immunity consists not only of antitoxins and antibacterial agents, but also of a resist-

ance which in a drug-habit patient we call "drug tolerance"—that is, that the tissue cell has so adapted itself to its environment that it is capable of carrying on its functions unimpaired in the presence of the poison. To do this it has to develop certain qualities, and these qualities are in the serum and can be transferred to the patient by oral exhibition, to produce in him exactly the same conditions as they were intended to produce in the animal originating them.

IV.—*The Treatment of Inflammation by the Oral Use of Antidiphtheritic Serum.*—In antidiphtheritic serum there are present along with antitoxin the properties in the serum which the animal has elaborated for its defence against the proteolytic and albumose-producing and the paralytic and muscle depressing elements in the toxic culture.

The writer has defined these properties as being an increased capacity for resisting proteolysis and an increased recuperative power in the muscle affected by the organism—the involuntary muscular systems. These properties are in the serum, and their specific effects can be obtained by their oral exhibition, not only in diphtheria, when given in time, but also in inflammation due to the staphylococcus, streptococcus, and bacillus coli communis as well as that arising from simple traumatism. Along with the antitoxin they, with other properties as yet unrecognised form the expression of the whole resistance of the animal to the injections of the diphtheritic culture. Unlike the antitoxin, they are absorbed and made available by the mouth and are operative in the presence of other infections as well as where no infection is present. These two properties are all that have been defined, as yet, but there are probably others in the serum, as both in experimental and clinical work a decided leucocytosis has been clearly manifest where required. Whatever, in fact, has been necessary for the animal to produce for its own effective defence against the organism will be included in the serum. The fact that these properties, while available against the infection for which they were elaborated, are also potent in other infections and where no infection exists, proves that they are entirely distinct from antitoxin, and the conclusion arrived at is that they are the elements in the serum intended for the maintenance of function and integrity of tissue unimpaired in the presence of the infection for which they were originally produced, and hence being tissue resistances they are available against all attacks on the integrity of these tissues by agents similar in their character and requiring the same defence as the original organism or toxic culture injected.

For inflammation, we thus possess in the antidiphtheritic serum three properties—(1) a muscular recuperative power which is the agent mainly effective against the streptococcus; (2) an anti-proteolytic power which is effective against the staphylococcus (proteolytic in its action) along with the muscular recuperative; (3) a hæmopoietic reaction leading to increased leucocytosis where required.

The essential vascular lesion in inflammation is the blood vessel wall, and in it the main element is the unstriated muscle. In this there is loss of tone varying according to the conditions producing it. Recovery is produced when this tone is restored, and this is Nature's own method. Anything, then, which will restore the normal tone or directly assist in doing so will be acting on parallel lines with normal recovery, and by so much increase the certainty, thoroughness and rapidity of the results desired. Here the recuperative power of antidiphtheritic serum fulfils all the conditions required, and its use so strongly reinforces the normal effort that further extension is prevented and recovery follows rapidly, ensured by an increased tissue resistance of which the patient alone, unaided by serum, was totally incapable. The soil having been rendered unsuitable for the pathogenic action of the organism, it is readily overcome and eliminated if the tissue tone in the meantime is maintained. Should the serum be discontinued prematurely the tissue tone

at once falls below what is required to prevent the pathogenic action of the organism and the inflammatory process very soon reappears, the organisms not being affected directly by the action of the serum and sufficient time not having been given for the opsonic, agglutinative, antibacterial, or whatever agent is present to aid in their elimination, to completely remove the infection present.

In the same way, the proteolytic action of the staphylococcus is inhibited by the action of the serum, making the soil an unsuitable field for the digestive action of that organism, and the anti-proteolytic action of the serum being maintained by the regular administration of the proper serum in sufficient dosage leads to exactly the same result as has already been described in the process as applied to the involuntary muscle. Hence where there is an invasion involving both the muscular tissue and the digestion of tissues there is present in the serum the necessary elements to enable the tissues involved to make an effective resistance.

Increased leucocytosis is not seen where the use of the serum rapidly overcomes the pathological conditions present exactly as in normal conditions, when serum is not being used. Where, however, the resistance is greater or where there is loculated pus, then there is a greatly increased leucocyte count. This is seen both in animals experimentally and in man clinically under the use of serum orally. In the treated animal there is an increased reaction with a greater leucocytosis, a larger amount of pus, and a more rapid maturation is observed than in the control animal. In man, where the pus is contained in firm tissue, the patient will discontinue the serum, as it gives more pain with every dose from increased tension in the abscess. It is probable that this local condition is due to the increased vaso-motor tone, local and general. Locally the renewed tone of the vessel wall leads to a contraction of the congested area around the focus, and this, with the increased general vaso-motor tone, causes a concentration of effort on the focus itself more than would be possible in normal conditions, and thus leads to the more intense reaction seen in the lesion.

From the nature of the action of serum on the tissues it must be clear that the earlier in the pathological process its action is obtained the less repair will be required and the more rapid and satisfactory the result obtained. While its action offers hope to the practitioner who has come to the end of his resources in a case and is ready to grasp any straw, that is not its legitimate field any more than it would be legitimate to leave our cases untreated till they became desperate. To obtain all that it is capable of doing for the pathological conditions within its range of action, it must be used in the earliest possible stage of the disease and depended upon to treat the case instead of being something to fall back upon as a last resource when everything else has failed. Used thus, it has in the writer's hands, and in those of his friends who have tested it, proved itself even more reliable in the treatment of inflammation by its oral exhibition than it has done hypodermically for the infection for which it was originally produced. The capacity for tissue restoration is seen in the rapid healing of wounds, whether septic or non-septic.

In the septic condition, where drainage is good, the pus is rapidly lessened, the wounds take on a healthier look, and the healing processes are strongly reinforced. Where drainage is not good or where a slough is present in a lesion such as a carbuncle, the rise in tissue tone shows itself by an increased reaction, and the greater amount of pus discharge. This leads to separation of the slough rapidly, and below it is found a healthy, granulating surface which under serum administration very quickly heals, while the patient's whole involuntary muscular system is raised in tone and the usual debility is materially decreased.

(To be concluded in our next.)

SIR WILLIAM BROADBENT recently celebrated his seventy-first birthday.

CLINICAL RECORDS.

A CASE OF COINCIDENT INFECTION WITH DIPHTHERIA AND TYPHOID FEVER.

By J. T. C. NASH, M.D. EDIN., D.P.H. CAMB.,
Medical Officer of Health for Southend.

THE comparatively rare combination of the coincident infection of a person with both diphtheria and typhoid fever induces me to briefly relate the history of the following case:—

A female child (Jewess), æt. 10, arrived in Southend indisposed, and was admitted to hospital as suffering from diphtheria on August 16th, 1905. The history data were: Sore throat on August 12th, headache and vomiting on the 13th. Diphtheria antitoxin (? units) administered before admission.

On admission the temperature was subnormal (97° F.). A clinical examination showed membranous deposit on both tonsils, but no adenitis nor nasal discharge. The tongue was dirty and there was an absolute loss of appetite. A characteristic diphtheritic odour was noticeable, and typical Klebs-Löffler bacilli found on bacteriological examination.

Treatment.—Diphtheria antitoxin (P. D. and Co.), 2,000 units on admission. Milk diet. A mixture of euclorine and liq. strych. (P.B.) 24 minims per diem. On the 22nd, it was noted that although the throat was cleaning there was no improvement in the appetite or in the state of the tongue. A mixture of rhubarb and soda was prescribed. On the 24th, I considered it advisable to resume strychnine (giving 20 minims per diem in combination with iron).

On the 30th, the patient complained of cramping pains which apparently were felt in the fasciæ of the muscles of the right thigh and the left foot.

On the 31st, the pains had extended to the left thigh and calf and to the right foot.

Sodium salicylate, gr. 15, every four hours, was prescribed. On September 1st, an antitoxin rash was seen on the face and legs, and the patient vomited.

On September 2nd, the temperature was found to be raised (100·6° F.), and the pulse 110. The tongue had remained coated and the appetite poor since admission on August 16th. A mixture of rhubarb and soda was again tried alternating with liq. strych., minims v., ter in die.

The morning (8 a.m.) and evening (8 p.m.) temperatures for the next few days were registered as follow:—

Sept. 3rd, 1905.—Morn., 99° F.; even., 100·4° F.

4th.—Morn., 100° F.; even., 101° F.

5th.—Morn., 98·6° F.; even., 100·6° F. Vomited

and complained of headache. A suspicion of typhoid fever entertained.

6th.—Morn., 101·8° F.; even., 102·6° F. Three macular spots seen on abdomen, fading on pressure. Mist. euclorine. Diet: Milk, beef-tea, 1 egg. (Widal reaction 40 per cent. positive in a 1 in 30 dilution.)

7th.—Morn., 100·2° F.; even., 101·4° F. P.120. Quin. sulph. gr. v. bis die.

8th.—Morn., 99·4° F.; even., 99·2° F. P.115. Calomel gr. ½.

9th.—Morn., 100° F.; even., 103° F. P.120. Mistura. acid. Nitro-hydrochlor. dil.

10th.—Morn., 101·6° F.; even., 100° F. A suspicious loose pea-soup-like stool with specks of undigested milk. Milk—freely diluted.

11th.—Morn., 102° F.; even., 102° F. Dark liquid stools; a few more spots on abdomen; spleen not palpable. Diet: *Whey*, beef-tea, and 1 egg.

12th.—Morn., 101° F.; even., 99° F.

13th.—Morn., 102° F.; even., 102·4° F.—A few more spots; slight deafness.

14th.—Morn., 100·4° F.; even., 102° F. Small sloughs in motions with small curds of undigested milk.

A four-hourly temperature charted since September 9th, showed a more characteristic typhoid fever

temperature than the 8 a.m. and 8 p.m. records. On September 15th, a positive Widal reaction was obtained in fifteen minutes. Two half-drachm doses of castor oil were prescribed to clear out the undigested curds present in the intestines.

On September 16th, the patient was placed on grey-powder gr. $\frac{1}{4}$, ter in die Lemon jelly given. On the 18th, typhoidal deafness was marked. The motions were pale and semi-formed. Liq. strychninæ 3 min. ter in die.

On the 19th, acetozone (xx. grs. to 2 pints of water) administered *ad. lib.* Amount of urine, 20 ozs. The patient very wasted. On September 20th, diluted milk (1 in 4) given. On the 22nd, the temperature touched the normal again. Urine, 14 ozs. Oil enemata prescribed (patient constipated). On the 23rd, better in every way. *Appetite better than since admission* on August 16th. Boiled custard, boiled bread and milk, and a lightly boiled egg permitted.

On September 26th, the temperature was still irregular, varying between a degree above and a degree below the normal line. *This is generally an indication of insufficient nourishment after an exhausting illness.* The dietary was improved to the extent of permitting thin slices of bread and butter and some boiled strained apple.

On September 28th, the temperature was more settled and fish was added to the dietary.

On October 1st, a mixture of iron and perchloride of mercury was prescribed, the temperature now keeping sub-normal.

On October 4th, the patient was allowed minced meat and thereafter rapidly improved. On October 13, on examining her mucous membranes, in anticipation of her early discharge, I found a few crusts in the nose under which the nasal membrane was slightly congested; a swab showed the presence of diphtheria bacilli. The crusts were cleaned away, and pure Izal applied to the diseased mucous membrane. No diphtheria bacilli could be found on October 17th.

The patient was discharged on October 20th, daily increasing in weight, able to walk, and with a good appetite.

Remarks.—As to dietary, I treated this child on the principle of treating the patient, not the disease (as is my usual custom in typhoid fever cases). Had this child been kept too long on a limited diet she would in my opinion have succumbed.

Realising the physiological and psychological moments for increasing the dietary saved the patient's life.

THE OUT-PATIENTS' ROOM.

ROYAL FREE HOSPITAL.

Multiple Gummata of the Leg.

Under the care of T. P. LEGG, M.B., B.S.(Lond.), F.R.C.S.

THE patient was a man, æt. 35, who came complaining of multiple ulcers and swelling of one leg; this had been going on for four or five months; there was not much pain and he had had no previous treatment except a local application of some ointment which he had procured from a chemist. There was a history of primary syphilis dating from the time he was in South Africa, that is to say, four or five years ago. On examination numerous ulcers were found on both the back and front of the left leg below the knee; some of the ulcers had a characteristic horseshoe shape, others were circular and arranged in groups, and some had run into one another, so as to produce an irregular outline; all of them had steep edges, smooth bases, and some were covered by a yellow slough. The tibia was very much thickened by the deposition of new bone; the lower end of the femur was uniformly increased in circumference by a smooth deposit of bone; the knee joint was enlarged by somewhat irregular thickening of the synovial membrane, the skin over the

knee and the lower end of the femur being natural, whilst that on the lower part of the leg was very much thickened and hardened from infiltration by inflammatory changes. The general condition of the patient was good and there were no other lesions of a similar nature. The case, Mr. Legg said, was a typical one of multiple cutaneous gummata together with an osteomyelitis of the lower end of the femur, and of a considerable length of the tibia as was shown by the uniform thickening of these bones. The synovial membrane of the knee joint was also involved in the gummatous change. As regards the treatment, Mr. Legg remarked there were several points to be considered—first, the local treatment, which he considered almost as important as the general treatment; in these cases there was very often a septic element present which had to be combated; this was best accomplished by dressings containing mercury which can be frequently changed. One of the best methods of applying the drug locally is, he thought, in the form of a powder containing calomel, say 20 grs. to the ounce made up with boracic acid; the addition of iodoform, 15 grs. to each ounce, is often beneficial but on account of its odour, one does not often use it. Hot fomentations should be applied and changed at not longer intervals than four hours; the limb should be washed every night and morning. Some patients, he pointed out, complain of the smarting and pain caused by the application of the powder, and in these cases, a mercurial lotion should be substituted. Internally, iodide of potassium and mercury should be administered, the latter being given in the form of a pill, of hydrargc. C. creta 2½ grs., night and morning; this was, he considered, a better way of giving the drug than in a mixture of the two which, often, the patient cannot take. The iodide should be given in doses of 10 grs. to begin with, and, if necessary, increased to 20 grs. or sometimes 30 grs. three times a day, and the patient is instructed to take a tumbler full of water with the medicine, the reason for this being that symptoms of iodism are not so readily set up when the iodide is well diluted. In addition to the constitutional treatment, the general treatment, he thought, is of great importance and therefore instructions as to diet of the patient should be given; this should be wholesome and readily digestible, alcohol being forbidden. If the general health of the patient is good the results of these lines of treatment, he remarked, are excellent, but when the patient is feeble, half starved, and especially alcoholic, the improvement is often not observed. This point had, been, he said, well illustrated in the case of a woman who had come to his out-patient room a few months ago, and a second time a few weeks ago; she was half starved, very hard worked, and given to alcohol; she had symmetrical gummata on the anterior aspects of both knee joints, the pre-patella bursa on both sides being the seat of a gumma; very little improvement followed treatment carried out for several weeks. The effects of treatment in the man were at once evident, the ulcers being practically healed in three or four weeks and the thickening of the synovial membrane being perceptibly less; the enlargement of the femur and the tibia had also diminished.

OPERATING THEATRES.

CANCER HOSPITAL.

CARCINOMA OF THE UTERUS—WERTHEIM'S OPERATION.—Mr. BOWREMAN JESSETT operated on a woman, æt. 43, for advanced cancer of the uterus. The os uteri was extensively affected as well as the cervix, the surrounding areolar tissue being also invaded by the growth. The vaginal walls were not affected, and the uterus was slightly mobile. The case was clearly one not suitable for vaginal hysterectomy, but it was thought to be a fair subject for Wertheim's operation. A week before the present operation the patient was anaesthetised, placed in the lithotomy position, the

diseased portions of the uterus scraped away, and the surface thoroughly burnt with a Paquelin's cautery; the woman was then returned to bed. The patient was now again put under an anæsthetic and placed in the Trendelenburg position; the abdomen was opened by a median incision between the umbilicus and the pubes. Doyen's retractor was then placed in the wound, and thus a good view was obtained of all the pelvic organs. The uterus was withdrawn through the incision with vulsellum forceps, the utero-sacral ligament divided on each side and the ureters found and traced downwards to the cervix uteri. After the bladder and the anterior fold of peritoneum had been reflected from the uterus, the Fallopian tubes and round ligaments were ligatured on each side and divided. The index finger was next passed in front of the ureter on the right side beneath the uterine artery, which last was then ligatured and divided; the same process was attempted on the left side, but it was found that the ureter had become embedded in the cancerous growth and parametrium, and in endeavouring to separate this the ureter was torn across. Mr. Jessett then ligatured the uterine artery on that side and carefully removed the diseased structures from the vesical end of the ureter, and with some difficulty opened up the vault of the vagina. A flap of peritoneum was removed from the posterior part of the uterus, the vagina opened up in Douglas's pouch, and the uterus removed. Mr. Jessett then proceeded to unite the upper and lower ends of the torn ureter on the left side. The peritoneum was stitched over the floor of the pelvis and a large gauze drainage passed down through the vagina. The abdominal parietes were closed in three layers, and the patient returned to bed. Mr. Jessett said that this was only the third case of Wertheim's operation he had performed, and he did not agree with Wertheim that such cases as the one just operated on were suitable for it; for, should the disease extend so as to implicate the ureters and extend round about the cervix and parametrium, he had come to the conclusion that operations for the removal of the uterus by Wertheim's or any other method were better left severely alone, as he was quite sure that the disease would recur under any circumstances within a very short time.

The patient made a tardy recovery, and left the hospital about five weeks after the operation. The left ureter for five days after operation appeared to be firmly united, and to act normally; after that the urine escaped from the sloughed ureter by the vagina, and the patient was left with a urinary fistula.

ST. PETER'S HOSPITAL.

PAPILLOMA OF THE BLADDER.—MR. THOMSON WALKER operated on a female, æt. 38, who had been admitted suffering from pyuria. She gave the following history: Three years ago she first noticed that her water was thick; this came on suddenly and disappeared as suddenly. From that time onwards she had repeated attacks of pyuria, which lasted two or three days and came on at intervals of from three to six months. During the attacks of pyuria she suffered from frequent micturition, but in the intervals she passed urine three or four times during 24 hours. She had once passed a clot, but there had been no other sign of hæmaturia. When seen by Mr. Walker in August, 1905, the urine showed a heavy deposit of pus, but no blood was present. She had never passed a stone or gravel. She was unable to come into hospital for cystoscopy at that time, and this attack, like the others, passed off. In January, 1906, there was some pain and tenderness in the right kidney. On

cystoscopy, a small papilloma about the size of a thumb nail was seen lying outside and to the right of the right ureteral opening. The bladder was opened above the pubes, and the growth demonstrated. The pedicle was clamped with rectangular forceps, and the growth cut away with scissors. The base was then seared with the electro-cautery and the forceps removed. The bladder wound was stitched with interrupted catgut sutures which did not penetrate the mucous membrane, and a large catheter was tied in the urethra. Mr. Walker said that the peculiarity in this case lay in the symptoms; pyuria was rarely a symptom of papilloma of the bladder, and in this case might have led to a mistaken diagnosis and possibly to an operation upon a healthy kidney. The presence of papilloma was demonstrated by means of the cystoscope where its presence could not have been suspected from the symptoms. It was not always advisable, he pointed out, to suture the bladder even after removal of an aseptic growth in cases where the bleeding had not been completely controlled; it was much safer to drain the bladder supra-pubically for a day or two than to run the risk of a bladder full of clot blocking the outlet and leading to rupture of the vesical wound. When the bladder wall was sutured it was well, he thought, to insert a small drain into the pre-vesical space for 48 hours in case of leakage. The tube should not, however, be left in too long for he had seen in another case a copious discharge of pus, that at once ceased on removal of the tube, which had been retained for eight days.

A week after operation the patient was doing well, no leakage having taken place through the supra-pubic wound.

NEW INSTRUMENTS AND APPLIANCES.

A MODIFICATION OF BANDL'S INTRA-UTERINE SOUND.

USERS of Bandl's hollow intra-uterine sound know that this valuable means of applying caustics or other medicaments to the interior of the uterus possesses the great drawback that in its usual form it is most difficult to clean. Blood from the cervix collects in its lumen, and when then acted upon by an astringent, such as pyroligneous acid, forms a firm clot, which it is most difficult to remove. Recently I pointed out this difficulty to Messrs. Arnold and Son's traveller, and suggested to him that a sound should be made composed of lateral halves, held together at the handle by a screw and above by a collar or small cap. The accompanying drawing shows the manner in which the firm

A. Sound ready for use. B. Lateral halves. C. Screw for extra top.

in question have turned out the sound, and in this form I consider that it offers a great advantage over the older form. The detachment of a single screw allows the halves to separate, there are no projections or holes in which dirt can collect, and several different-sized sounds can be attached to the same handle. When not in use, the parts of the spare sounds are held together by a small screw cap.

HENRY JELLET, M.D., F.R.C.P.I.,
Gynecologist and Obstetrical Physician to Dr. Steevens' Hospital,
Dublin &c.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD JANUARY 26TH, 1906,
The President, Mr. CLUTTON, in the Chair.

DR. H. D. ROLLESTON showed a case of Multiple Lipomas (Adeno-lipomatosis). The patient, a man, *æt.* 43, had noticed fatty tumours in the neck for about four years, but until his attention was drawn to them was not aware of the others. The multiple lipomas were almost everywhere symmetrical. There were lipomas on both submaxillary and parotid regions, in front of the temporo-maxillary articulations, in both supra-clavicular fossæ, in the axillæ, on the posterior aspects of the arms over the triceps muscle, in the pectoral regions, over the recti abdominis muscles, where they were not symmetrical, in the right groin, and outer side of right thigh. There were none on the legs or forearms. The lipomas in the neck, by fusion, would probably lead to a diffuse lipoma before long. There had recently been some pain in the lipomas on the right side of the abdomen and in the right groin, but the other lipomas were neither painful nor tender, and pain had not preceded the appearance of the lipomas, as is the case in *adipose dolorosa*. No enlarged glands could be felt in connection with these lipomas, which, in their distribution, resemble that in so-called "adeno-lipomatosis." The knee-jerks were present; there was no loss of muscular power. The thyroid could not be felt. There was no epistaxis.

The PRESIDENT pointed out the surgical importance of distinguishing between the diffuse and the encapsulated lipomata.

Mr. W. G. SPENCER discussed the pathology of the condition and speculated as to whether the vascularity or the fatty growth was the initial change.

Dr. ROLLESTON, in reply, said that he thought that as a rule the diffuse cases began as localised tumours. As regards the pathology of the condition, he could only suggest that the hæmorrhages and the fatty growths were both due to a common factor, disease of vessels due to alcohol.

Mr. JOHN R. LUNN showed a case of (?) General Paralysis of the Insane in a boy, *æt.* 16. The mother stated he had always been untrustworthy with money, and she thought he was a kleptomaniac. He had had three unconscious fits, April 15th, September 9th, and September 15th, 1905. Since having the fits he had become duller, and had had occasional twitchings of the left arm and leg. He walked with his left arm flexed, abducted, and hand flexed on the forearm, and dragged his left leg. There were no tremors, but there appeared to be some weakness of the elevating muscles of his mouth, but neither facial muscles were affected. Some weakness of the left arm and hand. Sensation over the body normal. Speech not affected. Sphincters normal. Reflexes: left elbow and wrist present, but not present on the right side; patella reflex brisk on both sides; no clonus. Left pupil larger than right (contracts under guttæ eserina). No ocular paralysis. No changes in the fundus. There was no history or evidence of syphilis.

Mr. JOHN R. LUNN showed a case of Myasthenia Gravis (?) in a man, *æt.* 39. The last seven years there had been weakness of his hand and neck muscles. The patient stumbled when he walked. *Nervous System*.—Motor weakness of arms, forearms, hands and legs; the fine movements of the fingers were lost. Flexion and extension at the elbows were weak. The anterior tibial muscles of both legs were weak, and there was foot-drop. Some loss of power in the face muscles, and ptosis. His eyes could not be raised above the horizontal: paresis of both orbiculares oris and palpebrarum and some weakness of both occipito-frontales muscles. Right supinator longus muscle and right interossei were wasted. Some contraction

of the sterno-mastoid muscles, but not sufficient to raise his head from the pillow when in bed. *Sensory*.—Tactile sensation to heat and cold normal. Both knee-jerks and plantar reflexes absent; hypogastric and epigastric reflexes present. The tongue did not appear wasted; taste normal. The pupils react to light and accommodation; no changes in the fundus. Speech blurred, the blurring increased by talking; some slight difficulty in swallowing. All the wasted muscles reacted to faradism, but not well, and a strong current was necessary; they did not react to galvanism.

Dr. FARQUHAR BUZZARD said that apart from the muscle atrophy, this case would be called an undoubted one of myasthenia gravis and he could think of no other category into which to place it. Recently muscular atrophy had been described in several undoubted cases.

Mr. JOHN R. LUNN showed a case of Molloscum Fibrosum in a man, *æt.* 22. Present condition was first noticed eighteen months ago. Six months ago he had been obliged to give up his work as some lumps appeared on his face. Two lumps on his toes had disappeared, leaving only slight scars. He had experienced no pain in the swellings, only slight itching at night-time when he got warm in bed. There was no family history of any kind of tumour. *Present condition*.—Healthy-looking man. The patient's trunk was covered all over with tumours, varying from the size of a millet seed to that of a cherry; most of them were sessile, but a few were becoming pedunculated; they were movable on the deeper structures, and adherent to the skin, which was rather thinned over their centres. The distribution did not appear to correspond to any nerves. He had had arsenic and thyroid tablets by the mouth, but no changes in the tumours had taken place. Two of the tumours were excised for examination and sent to the Clinical Research Association. "The larger of these two tumours is a localised, but not encapsuled growth of fibrous tissue, plentifully nucleated and containing blood-vessels and nerves. The presence of the latter, with their concentrically-arranged sheaths, is of some importance, pointing to the probability that this fibroma has arisen from the nerve sheath, and is therefore a neuro-fibroma. The fact that the growths are multiple is also in favour of this, but it does not necessarily follow. The smaller tumour is more diffuse in appearance, and there are no nerve fibres to be recognised in it. Neither of these tumours shows any sign of malignancy."

Mr. LAWRIE MCGAVIN had seen a similar case, which however, had developed a tumour on the sciatic nerve. On excision this tumour proved to be a spindle-celled sarcoma.

Mr. LAWRIE MCGAVIN showed a case of Laminectomy for Traumatic Paraplegia. The patient was a man, *æt.* 36. A steel plate twenty feet long and four feet wide had fallen across his back. On admission there had been complete loss of sensation and motion in both lower extremities; the scrotum and penis were partially anæsthetic; there was complete absence of knee-jerks and of plantar reflexes, and the bladder and rectum were paralysed, as was also the sphincter ani. A depression was found over the spine of the first lumbar vertebra deep enough to meet the tip of the finger. The patient was submitted to operation three hours after the injury. The spinous processes and posterior halves of the first and second lumbar vertebra were found to be completely detached, and forced down upon the cord; the left lamina of the second lumbar vertebra was comminuted, and a portion of this bone was found to have been pushed forward between the cord and the transverse process. The whole of the detached bone was removed, and the wound was closed except for the presence of a horse-hair drain at the lower angle. Twenty-four hours later sensation had returned in the right leg and thigh, and the foot and ankle could be moved. On the following day sensa-

tion returned in left leg and thigh, with the exception of the area supplied by the genito-crural nerve and the lesser sciatic. In three weeks the paralysis of the rectum and bladder improved; and under massage and faradisation the motor and sensory functions have gradually returned, although the left leg and thigh still remain feeble. The patient was now able to walk without the help of either crutches or sticks; the right knee-jerk was still delayed and feeble, and the plantar reflexes were absent.

The PRESIDENT commented on the absent reflexes as being usually regarded as a contra-indication to operation.

Dr. C. E. BEEVOR explained that the significance of the absent reflexes was different according as the lesion was in or above the lumbar enlargement. In the former instance, as in this case, operation was indicated, not so in the second instance.

Mr. JAMES BERRY showed a case with Congenital Aperture in the Centre of the Palate. The patient was a woman, *æt.* 16. The aperture is symmetrical and oval, 7 mm. long and 5 mm. wide. Two-thirds of the opening were in the hard palate, one-third in the soft. The edges were thin. On either side of and behind the opening the tissues were thinner than is natural. The uvula and posterior edge of the soft palate were congenitally cleft. There was no harelip nor any other defect of development except those mentioned. The mother stated that the opening in the palate was noticed soon after birth, and that it was then "nearly covered with a thin membrane."

The PRESIDENT suggested congenital syphilis as a possible diagnosis.

Dr. ESSEX WYNTER remarked that the presence of the bifid uvula supported the diagnosis of a congenital defect.

Mr. BERRY, in reply, said that he could find no evidence at all of syphilis.

Dr. C. H. THOMPSON showed a case of Shaking Head or Spasmus Nutans in a girl *æt.* 8 months. In the first week in December, when the child was six months old, her mother had noticed movements of her head and eyes, which had continued up to the present time. She lives with her parents and two elder children in a dark back room in a basement in Soho. There was no history of injury or fits, and there were no signs of rickets, although sweating about the head at night and throwing off of the bedclothes had been noticed. *Present condition.*—There were almost continuous movements of the head, both lateral and to and fro, while the child was awake. The movements ceased during sleep and when the eyes were bandaged. They also ceased if the child grasped any article and became intent on obtaining it. There was marked nystagmus, lateral, rotatory, and vertical. These movements of the eyes became more marked when the head was grasped and steadied.

Dr. J. WALTER CARR showed a case of Amyotrophic Lateral Sclerosis in a man, *æt.* 33. His present illness had begun about four years ago with weakness and wasting of the right hand; two and a half years ago the right leg had begun to get weak and stiff. A year ago weakness had been first noticed in the left arm, and during the last few months in the left leg. At the present time the legs presented well-marked spastic paraplegia, with extensor plantar reflex, exaggerated knee-jerks, and, on the right side, ankle clonus. There is some *pes cavus* on both sides. The arms showed distinct flaccid paralysis, affecting mainly the small muscles of the hands, and, to a much less degree, some of the shoulder muscles. Fibrillary twitchings were very marked in nearly all the affected muscles. The intrinsic muscles of the hands showed a partial R.D., nowhere complete, except that the right first dorsal interosseous gave no reaction to either current. There was no affection of sensation, of co-ordination, nor of the sphincters, and no indication of any bulbar paralysis, except slight weakness of the right facial muscles. There was well-marked nystagmus of the

right eye, but this is perhaps connected with the blindness of the left eye due to ophthalmia neonatorum.

Dr. W. P. HERRINGHAM showed a case of Transverse Myelitis, with Recovery, in a man, *æt.* 29. Nine days before admission he had had pains in legs and back, which had got worse. His arms had become weak, and he had lost control of his sphincters. Loss of power and anæsthesia had rapidly developed in his legs. On admission there was paralysis of the intercostals, diaphragm, and legs. The arms were weak. There was anæsthesia of the legs, which soon spread upwards as far as the level of the nipples. His condition gradually improved until now, nine months later, he was able to walk about unaided. He still had some weakness of the sphincters, but this was improving. His knee-jerks, which could not be obtained during the early part of his illness, were now present on one side.

Dr. C. E. BEEVOR suggested that the case was one of peripheral neuritis, in spite of the affection of the sphincters. The recovery of the knee-jerks showed that they could not have been lost from a transverse myelitis above the lumbar enlargement.

Dr. HERRINGHAM, in reply, said that the retention incontinence did not suggest a lumbar region. The upper paralysis of the arms and diaphragm had very rapidly recovered. The severe bed sores were strongly in favour of myelitis.

Mr. P. MAYNARD HEATH showed a case of Charcot's Disease in the Thumb, of a man, *æt.* 45. The patient had cut his left thumb with a saw three months ago. There had been some inflammation about the part, but the wound had healed. Soon after the thumb had begun to swell. A month later the skin had become red, and lately the swelling had become much greater. There had been very little pain. At the present time the thumb was very much swollen, and the skin was red and in parts scaly. The swelling was most marked over the interphalangeal articulation, and this joint was disorganised. The metacarpo-phalangeal articulation was normal. There were well-marked signs of tabs. The knee-jerks were unobtainable. The pupils showed the Argyll-Robertson phenomenon, and Romberg's symptom was present.

Dr. C. E. BEEVOR commented on the extreme rarity of this localisation of the joint affection, but the diagnosis was beyond doubt.

Mr. HEATH quoted a series of interesting statistics taken from, amongst other sources, Henderson's paper in the *Journal of Pathology* of 1905.

Dr. BERTRAM ABRAHAM showed a case of Sudden Paralysis of the Third Cranial Nerve in a woman, *æt.* 43. For the last month there had been twitching of the left eyelid. On January 18th and 19th she had been drowsy and sleepy, and had had frontal headache. On the morning of January 20th she found that she saw objects double; the left eye was partially closed, and during the morning the closure became complete. There was no history of syphilis. *Present Condition of eyes.*—*Left*: slight elevation of eyebrow; complete ptosis; slight proptosis. Pupil three-quarters dilated; not quite circular; did not react to light or accommodation. Eye deviated outwards at an angle of about 25°. Movement *outwards* unimpaired, *inwards* not beyond centre of orbit, *upwards* lost, *downwards* lost except a slight downward movement with inward rotation (sub. oblique). *Right*: normal, transverse axis greater than vertical. No iritis; disc and fundi natural. There was crossed diplopia, both horizontal and vertical. In horizontal meridian, the false image was below and to right of line. In vertical false image was below line with downward movement, and above it with upward. When the image was on the level of the centre of the eye it was single.

The other cranial nerves and the rest of the nervous system were natural. There was a systolic bruit at the cardiac apex, and a to-and-fro murmur at the aortic base. The liver was enlarged, the dulness extending to two fingers-breadth below the costal margin in the left mammary line. There was no other abnormal physical sign. The palsy was in an early stage, over-

action of the external rectus and radial dilator of the iris not having developed.

The PRESIDENT commented on the possibility of moving the limb in the adducted position, which is unusual with coxa vara.

Mr. BUCKNALL, in reply, agreed with the President that the case could not be one of the usual varieties of coxa vara. He thought the affection was possibly congenital.

Mr. RUPERT BUCKNALL showed a case of Bilateral Deformity of the Neck of the Femur. The patient, a boy, æt. 9, who always had had difficulty in walking, which had increased as he had grown older. No history of injury; not thought to have had rickets; had been kept in bed during the past twelve months. The lower limbs were of equal size and length. The trochanter on either side lay higher than normal, its tip being three-quarters of an inch above Nelaton's line. Otherwise, when lying at rest the limbs did not appear abnormal. The head of the femur could easily be felt in Scarpa's triangle, much below the level of the great trochanter. Extension was perfect; flexion was good; adduction was slightly increased in range; abduction was remarkably diminished, both in the extended and flexed positions of the limb. When extended, the angle of abduction between the two thighs did not exceed twenty degrees. Internal rotation was slightly diminished. External rotation only could be carried out through half the normal range. The marked adduction of the thighs interfered with walking, and almost led to a cross-legged gait, and running was impossible. Skiagrams showed marked bending of the neck of the femur downwards.

The PRESIDENT suggested the diagnosis of leontiasis ossea.

Mr. KELLOCK, in reply, said that the asymmetry of the condition, together with the microscopic examination, negated this view.

Mr. THOMAS H. KELLOCK showed a case of Osteo-Sarcoma of Frontal Bone, in a man of 23. Between six and seven years ago the patient had first noticed a small hard swelling on the left side of the forehead just above the eyebrow; this had gradually increased in size; it had never been tender nor given rise to any pain or symptoms. A large tumour now involved the left half of the frontal bone and extended a little beyond the mid-line above the nose; it was 18½ inches in circumference, and rose about 4 inches above the level of the rest of the skull; it was densely hard, except in a few spots, which felt soft and elastic; the veins in the scalp over it were somewhat distended. The left eyeball was displaced downwards and forwards, but there was no diplopia. There were signs of optic neuritis in both eyes. A skiagram showed the tumour to be chiefly composed of bone, but the periphery was irregular. The patient's general health was bad but had been excellent, and he had followed his occupation up to the present time. On January 2nd an exploratory incision had been made into the tumour by turning backwards a flap of the scalp, and the periosteum which overlay the growth had been separated. The surface of the growth was found to be soft, and microscopic examination of a piece that was removed showed it to be sarcomatous; the central portion of the tumour was very hard, and was with difficulty cut with a gouge. There was rather free hæmorrhage, which was arrested by the application of adrenalin solution. The wound was closed, and had healed by first intention.

Dr. A. E. GARROD referred to a similar case he had had under his care which was reported to this Society recently by Dr. Langmead. In this case the sigmoid was dilated and the attacks of tetany could be aborted by lavage of that organ.

Dr. BATTY SHAW, in reply, commented on the absent reflexes, and drew the analogy between the condition and the cord changes in another intestinal poisoning, pernicious anæmia.

Mr. H. T. MANT and Dr. H. BATTY SHAW showed a case of Tetany of seven months' duration associated with Gastro-Umbilical Disorder in a girl, æt. 9, appar-

ently cured by the use of thyroid substance. The patient had suffered from gastro-intestinal disorder for the last four years. For the last eighteen months she had been unable to walk because of weakness of the lower extremities, and during this period the abdomen had become much distended. There was marked peristalsis present. She had suffered from repeated attacks of tetany during the last seven months, and had become very pale, the blood examination showing severe anæmia. She was somewhat puffy in the face, and a firm œdema had been present in the feet and hands. The knee-jerks had been lost on a previous occasion, but returned, and the tetany disappeared under treatment in hospital with salol, etc. The same treatment had now failed and the knee-jerks were still absent. The attacks of tetany disappeared immediately after the use of thyroid substance, and though this remedy had been given for a week only, attacks had not recurred. The points of interest in the case were—

1. The long period (seven months) during which the attacks of tetany had been frequently reported.
2. The association with marked gastro intestinal disorder and distension of the alimentary tract.
3. The failure of the antiseptic treatment of the bowel, though on a former occasion it appeared to be successful.
4. The apparent prompt response to thyroid treatment.

Mr. HUGH M. RIGBY showed an infant, æt. 15 months with Plexiform Angioma of the Hand and Arm. The left brachial and radial arteries were dilated and tortuous, and communicated a well-marked thrill. The palm of the hand was occupied by a pulsating vascular tumour. The third part of the left subclavian artery was ligatured in February, 1905. Skiagrams showed gigantism of the bones.

Mr. HUGH M. RIGBY showed a case of Cavernous Nævus of the Tongue. The patient, a girl, æt. 11, was in the London Hospital eighteen months ago for cavernous nævus of the right border and dorsum of the tongue. In July, 1904, the right lingual artery and veins were ligatured, and the tumour apparently completely dissected out. The present condition showed a gradually increasing recurrence.

Dr. C. E. BEEVOR showed a case having Perforating Ulcers and Joint Changes with only slight sensory changes. The patient five years ago had had two fits, with paræsthesia all over right side, and loss of speech. He was in bed six months. He had been unable to move legs, which were stiff, for six weeks; power had returned gradually and steadily. Resumed business in nine months. Sphincters and sensation unaffected. Three years ago toes became stiff; blisters appeared on dorsal and plantar surfaces, which ulcerated. Three pieces of dead bone separated on various occasions; one was evidently distal end of terminal phalanx of great toe. Had pains in right ankle, but could walk with a stick until nine months ago, when pain in ankles worse; feet tender, painful if he trod on a stone. Gave up walking ten weeks ago.

Present Condition.—Some ptosis; slight overaction of frontalis. Pupils equal; react to light and convergence. Talkative, and apt to get confused; lisps. *Sensation.*—Slight difficulty in distinguishing between touch and prick, and also heat and cold on soles of feet and dorsal aspect of toes. Otherwise sensation was normal throughout. No lightning pains. Ankle-joints were stiff on admission, but now appear normal. *Muscular system* normal, except some difficulty in moving the toes; knee-jerks increased; plantar reflex gives flexion of toes. Right foot flat, bones of tarsus and proximal ends of metatarsal bones were large, but joints were movable actively and passively without grating. On admission to hospital there was much swelling of ankle, tarsus, and metatarsus and toes in both feet. This has diminished with rest in bed. Right toes: four external toes were now about normal size; formerly enlarged and stiff. Great toe much enlarged in the soft tissues, which were still larger on admission. Bones of metatarso phalangeal joint were large, but joint

moved well actively and passively without grating. Phalangeal joint quite disintegrated; formerly large perforating ulcer on under aspect, through which three pieces of bone have sloughed, one of which was distal extremity of terminal phalanx, which was absent in skiagram. Toe-nail had been lost many times. Left foot. Arch was not flattened as in right. Outer three toes normal. Great toe misshapen. Great enlargement of metatarso-phalangeal joint, especially in dorso-plantar diameter; considerable bony deformity all round joint; passive movement only possible, and grating was obtained. Fair movement, active and passive, in phalangeal joint; no grating, but joint was abnormally loose. Perforating ulcer less severe under this joint. Second toe abnormally thick and straight, seen from above, but had a large bulbous, soft swelling under the distal phalanx. Metatarsal joint much increased in dorso-plantar diameter; abnormal exostosis at the end of the metatarsal bone; movement of joint very limited; dorsiflexion impossible; no actual grating; movements of phalangeal joints almost absent. Nail was at the extreme end of the toe. The case was probably one of syringomyelia with slight sensory changes. Extraordinary bone changes were sometimes seen in syringomyelia, he had seen a case that had been operated on for leontosis ossæ.

Dr. W. P. HERRINGHAM showed a case of Addison's Disease. The patient, a man *æt.* 25, had had frequent attacks of diarrhoea and vomiting. He had been under observation for over two years, and still did hard work. The bronzing was diminishing. There was no reaction to tuberculin. A hysterical paralysis of the right leg with hemianæsthesia was present.

Dr. WALTER CARR had seen a similar association of Addison's disease with hysterical hemianæsthesia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD FRIDAY, JANUARY 12TH, 1906.

The President, Sir ARTHUR CHANCE, P.R.C.S.I., in the Chair.

REMARKS ON GASTRO-ENTEROSTOMY.

Mr. R. CHARLES B. MAUNSELL read a paper entitled "Remarks on Gastro-enterostomy, with Description of a New Clamp." He advocated operation in gastroptosis and atonic gastritis in addition to the more commonly recognised indications. He considered that there should be no fixed rule for the site or form of incision in the abdominal wall, or for the site of junction of the viscera, as the first would depend upon the amount of ptosis present, often lying partly below the level of the umbilicus on the left side, the junction of the viscera being made near the pyloric antrum, or at the most dependent portion of the stomach, according to the amount of muscular power present in the stomach walls. A new form of clamp was described and shown, it was made somewhat on the principles of Carwardine's intestinal clamp and held the parts neatly in position during the operation. A short *resumé* was then given of the various post-operative troubles and their treatment.

The PRESIDENT expressed himself in favour of clamps, and recognised the advantages of those designed by Mr. Maunsell. In some of his cases vomiting did not occur at all after the operation. He referred to the advisability of suturing the proximal loop of the jejunum to the meso-colon with a view to prevent subsequent internal strangulation.

Mr. BLAYNEY was not in favour of clamps, as he considered their use endangered risk of post-operative hæmorrhage. He had not known of any case in which dispensing with clamps had led to any untoward result through escape of stomach contents or prolongation of the operation.

Mr. JAMESON JOHNSTON was in favour of clamps, and had not noted hæmorrhage in any of his cases. He considered it essential that the anastomotic opening should be free, and that the direction of the peristaltic wave in the stomach and jejunum should correspond. He admired the principles of Mr. Maunsell's clamps.

Mr. WILLIAM TAYLOR had used clamps like those of Moynihan, but of a lighter build; he thought those of Mr. Maunsell were an improvement. He also thought hæmorrhage after gastro-enterostomy could be prevented if the sutures were properly introduced. He had seen one fatal case of vomiting due to the vicious circle.

Mr. EDWARD H. TAYLOR had been rather startled by hæmorrhage in one case after gastro-enterostomy, although he had used every precaution in the suturing process. At present his practice was, in making the gastric incision, to divide the muscular coats carefully and expose the principal vessels in the submucous coat and suture them separately before incising the mucous membrane. In some of his cases vomiting had not occurred once after the effects of the anæsthetic had passed away, and he had observed that those who did best in this respect were those in whom there was decided pyloric obstruction. Where the pylorus was fairly patent one was more likely to encounter post-operative vomiting.

Mr. W. S. HAUGHTON said he had sometimes experienced difficulty in making a sufficiently large aperture in the meso-colon, and he would like to know if Mr. Maunsell considered it likely that the vitality of the colon would be dangerously affected by dividing some of the colic vessels. Instead of clamps on the stomach and intestine he used strong fixation sutures, which held the parts steadily in apposition and facilitated accurate suturing.

Mr. KENNEDY said he had discontinued the use of the Murphy button in gastro-enterostomy. He had met with two cases of hæmorrhage where gastro-enterostomy had been performed some months previously; both recovered, however, under ordinary treatment.

Mr. MAUNSELL, in reply, said he had only meant to touch on a few points respecting the operation of gastro-enterostomy. His habit now was to suture the margin of the divided meso-colon along the line of gastro-jejunal junction. He always ligatured the larger vessels met with when incising the stomach. He did not think there was much likelihood of the peristaltic currents in the stomach and jejunum being reversed if ordinary care were taken. If he could not make the aperture in the transverse meso-colon large enough without tying vessels he tied them. The proximal jejunal loop should be long enough to enable it to be connected with the most dependent part of the stomach without tension. He considered that the vomiting was due chiefly to the anæsthetic.

PARTIAL GASTRECTOMY FOR PYLORIC TUMOUR.

Mr. WILLIAM TAYLOR read a paper on the above subject. The patient, a woman, *æt.* 60, was exhibited in perfect health, free from stomach trouble of any description, able to eat anything and everything without the slightest discomfort. The history dated back for three years, during two and three-quarter years of which she complained of ill-defined stomach trouble, to which she applied the term "weakness." During the three months prior to admission pain after eating became a very prominent feature of the case, but the pain continued after vomiting; in fact, she was never free from pain during this period, but food greatly aggravated it. At times it was so severe as to compel her to press her stomach across the back of a chair or edge of the table; at other times she rolled upon the floor in agony. About two months before admission she noticed a tumour forming, which increased very rapidly in size, and it was on account of this tumour and the severe pain and vomiting that she sought admission to hospital. On examination the tumour was found to be situated a little above and to the right of the umbilicus; it was hard, nodular, and

firmly fixed to the anterior abdominal wall. There was no tenderness. The stomach was moderately dilated. The patient herself was greatly emaciated. Examination of the gastric juice showed a complete absence of free hydrochloric acid. The diagnosis of malignant disease was made on account of the age of the patient, her cachectic appearance, the rapid growth, the hard, irregular nature of the tumour and the absence of free HCl. from the gastric juice. Exploratory laparotomy was performed, when it was discovered that by excising portion of the abdominal wall to which the tumour was adherent the growth could easily be brought outside. This was accordingly done, and as the tumour presented all the naked-eye appearances of malignancy, a partial gastrectomy was performed. The cut ends of the stomach were sewn up with two rows of silk sutures. The duodenum was freed by dividing the peritoneum over the right kidney and fixed by two rows of sutures into the opening made in the posterior wall of the stomach, about one inch beyond the line of section. What was taken to be oesophagus during this procedure was subsequently found to be a constriction, due to the healing of an old-standing ulcer, which had contracted and produced an hour-glass condition of the stomach. This condition was immediately remedied by the performance of gastroplasty. Two enlarged glands were removed from the lesser omentum, and the abdominal wall repaired. The entire operation occupied exactly seventy minutes, and the shock was very slight. Recovery was rapid and uninterrupted, and she left for the convalescent home on the twenty-third day after operation. Examination of gastric juice that day (Jan. 12th, 1906), seven months after the operation, showed that there was not a trace of free HCl, or, indeed, any other free acid to be found. The pathological report of the tumour demonstrated that it was apparently a mass of inflammatory material around an old-standing ulcer. Mr. Taylor then discussed the question of the diagnosis of inflammatory tumours from carcinomata, after which he went into the question of the operative treatment of gastric carcinoma involving the body or pylorus, and contrasted gastro-enterostomy with gastrectomy, both as regards the immediate mortality of these procedures and the average length of life after the performance of these respective operations. The comparatively small number of cures after gastrectomy was attributed to the inability to make a diagnosis sufficiently early, and Mr. Taylor advocated strongly more frequent recourse to Mr. Moynihan's advice, viz., "that one should operate not to confirm but to make a diagnosis."

Mr. MAUNSELL stated that the symptoms upon which he laid stress in the diagnosis of gastric cancer were absence of free hydrochloric acid, short duration of gastric symptoms and, in many cases, irregular pyrexia. In one case he had performed almost complete gastrectomy, but with fatal result. Quite recently he had operated on another case, and took away about half of the stomach, and the patient was making good progress. He thought that, short of cancer in the liver, every effort should be made to remove cancer of the stomach.

Mr. JAMESON JOHNSTON considered that the growth should be removed if possible, as much more benefit was likely to ensue than after gastro-jejunostomy.

Mr. HOUGHTON having also made some remarks, Mr. WILLIAM TAYLOR replied, and the Section adjourned.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, JANUARY 25TH, 1906.

Mr. PRIESTLEY SMITH, F.R.C.S., President, in the Chair.

Mr. SIMEON SNELL (Sheffield) related a case of SEPTIC THROMBOSIS OF THE CAVERNOUS SINUS. On May 1st, 1895, a medical man pricked a small

vesicle on the upper lip with a gold scarf pin which had been used previously to open an abscess, and which was thought to be clean. The next day there were redness and swelling, and later on that day he was obliged to go to bed. On the 5th the condition of the lip was worse and the blush extended to the left cheek and orbit. This was followed by proptosis and swelling of the conjunctiva and eyelids. Later the right side followed the same course, the proptosis being even more marked on this side. The movements of the eyeballs were interfered with, and there was paralysis of the right facial nerve and deafness on the right side, also dulness and evident effusion of the right side of the chest. The patient died fourteen days after the commencement of the illness, his mind having been unaffected throughout. Mr. Snell remarked that the initial lesion was that on the lip, which the medical attendants had considered to be malignant facial carbuncle. No *post mortem* was allowed.

Mr. SNELL also related the case of a pork butcher, æt. 48, who came to him with Acute Œdema of the Eyelids on both sides. The day before he had been dressing a pig, when the gut, which contained a large number of worms, burst, and the contents splashed into his face. The Œdema was present three or four hours later. When first seen by Mr. Snell, twenty-two hours later, the eyelids on both sides were intensely œdematous, projecting as large semi-transparent swellings, leaving only a chink between them. There was considerable chemosis of the conjunctiva. The next day the swelling had much subsided, and the day after the condition of the eyelids had almost passed away, though the conjunctiva remained red. The worms in the pig were the same class as *Ascaris Lumbricoides*, and in seeking an explanation for the condition, Mr. Snell mentioned that it had been recorded that these worms, when alive, give off an irritating vapour. From another pig in which worms had collected together, the contents of the gut were taken, and also nutrient broth into which some of the worms had been placed, after having been cut to pieces, and this created no irritation when instilled into the conjunctiva of a guinea pig.

Prof. A. MAITLAND RAMSAY, of Glasgow, read a paper on the

TREATMENT OF DETACHMENT OF THE RETINA. based on a record of fifty consecutive cases of detachment of the retina, treated in the Glasgow Ophthalmic Institution, during the four years ended October 31st, 1905. The active treatment consisted in sub-conjunctival injections of 5 to 20 minims of 1 in 2,000 bichloride of mercury with 8 per cent, chloride of sodium solution, the severe pain that always followed being mitigated by the addition of a few drops of 1 per cent. cocaine solution. The injection was repeated as often as might be necessary, at intervals of from four to six days; and if no decided improvement showed itself within a fortnight, free diaphoresis was induced by the sub-cutaneous injection of from $\frac{1}{4}$ to $\frac{1}{2}$ of a grain of pilocarpine, this alternating with the sub-conjunctival injections. If the site and character of the detachment were deemed favourable, the sub-retinal fluid was always evacuated by scleral puncture. The patient was kept prone in bed with his eyes bandaged, and every effort was made to improve his general well-being by careful attention to diet and to the action of the bowels, kidneys, and skin. Marked chemosis of the conjunctiva was essential, and when the reaction to the sub-conjunctival injections was absent or ill-marked, 1 to 2 per cent, of dionine was added to the bichloride and chloride of sodium solution. Of the fifty cases treated, ten showed a decided improvement, and thirteen a moderate improvement, though of the former group five, and of the latter group two, relapsed at intervals varying from two weeks to four years. The more recent the detachment the more favourable the prognosis, but the pathological antecedents of the affected eye were more important than the duration of the condition. Failure was the rule in all cases marked by a seriously degenerated choroid, a pupil sluggish to mydriatics, a much diminished tension,

and a red-coloured separation. The method of treatment outlined was simple, applicable to all cases, and, as far as the author's experience went, never did any harm.

Dr. D. J. WOOD related a case of

BITEMPORAL HEMIANOPSIA.

The patient was a man, *æt.* 33, who had suffered for over a year with frontal headache, failing vision and loss of memory. The vision of the right eye was 1-60 and the left 6-60, and there was bitemporal hemianopsia with contraction of the field and loss of fixation in the right. He was mentally dull and forgetful, and there was marked delay in answering questions. The pupils were sluggish, and the knee jerks were almost absent. During the 52 days he was in hospital he grew worse mentally, and on account of his foul language and filthy habits it was impossible to keep him in. After 62 days, during which there was little change, he suddenly sat up and began to ask sensible questions, and when seen some months later he was mentally quite well. His right eye showed optic atrophy, was blind and divergent. The left improved to 6-18, his patellar reflexes were normal, and his memory for events after his sudden recovery was good. He had no recollection of anything during the previous 3½ months. His history was given by his wife, brother-in-law, and mother, who all agreed as to the details. The case was thought to be one of cystic growth of the pituitary body, which during a fit of coughing had ruptured through the eroding bone and had escaped into the pharynx or nasal cavities, but nothing of this sort was noticed by the friends, and the patient was more or less unconscious until the actual relief of pressure had occurred.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST, ON JANUARY 25TH.

Dr. CALWELL, President, in the Chair.

Dr. R. W. LESLIE read notes of a case of

PERNICIOUS ANÆMIA

treated by cacodylate of soda. The patient was a lady over 60 years of age when she came under treatment last summer. She was extremely weak, vomiting continuously, and oedematous in the legs and under the eyes, and appeared practically moribund. She was given rectal injections of the drug, and rapidly improved. The blood count, which had been 703,000 red corpuscles, when she came under treatment, increased in three weeks to 1,900,000. Improvement was steady; she was able to be out in a month, and subsequently returned to her home in England. Dr. Leslie had lately heard from her medical attendant there that she continued to do well.

In his remarks on the case Dr. Leslie said that the point of interest was that while Professor Fraser said that the drug was inert, he had observed in this, as in several other cases he had previously reported in which marked improvement took place, there was a strong smell of garlic in the breath. Another reason against the supposed inertness of the drug was the fact that several cases of peripheral neuritis had occurred apparently from its use. To avoid the risk of this he used it for ten days, then remitted for ten days. He preferred to give it by the rectum to avoid sickness.

Dr. MITCHELL said that he had used cacodylate in keratin coated pills in one case with improvement, but the case relapsed after a year.

Dr. GARDNER ROBB read notes of two unusual cases of

PERFORATION IN TYPHOID FEVER.

The first case was a boy in whom all the symptoms of typhoid were latent till perforation took place, and the actual cause was only demonstrated *post mortem*. The second case was that of a man, in whom perforation occurred on the 123rd day, when he had been

partially convalescent for seven weeks or so. He could find no similar case on record.

Dr. A. B. MITCHELL showed several cases of surgical interest.

Mr. ROBERT CAMPBELL showed a boy of 9, in whom he had done decapsulation of the kidneys for chronic nephritis. Previous to operation the urine was scanty, with a large amount of albumin and casts, and the boy was dropsical. Since the operation he had steadily improved, and now the urine was nearly 40 oz., and contained only a trace of albumin. The dropsy had also disappeared.

THE CENTRAL MIDWIVES BOARD.

MEETING HELD JANUARY 25TH, 1906.

The President, Dr. CHAMPNEYS, in the Chair.

AFTER the Standing Committee had adjourned, Mr. WARD COUSINS moved: "That the Form of Suggestions accompanying the Agenda of December 14 for the guidance of the medical advisers of the Local Supervising Authorities, respecting the duties of Inspectors appointed to exercise general superintendence, be approved and issued to the Local Supervising Authorities."

Dr. PARKER YOUNG inquired if the local authorities would not deem such suggestions an impertinence?

Mr. WARD COUSINS said he was sure any suggestions from the Board would be welcomed.

The PRESIDENT suggested that a Committee be formed to consider and make suggestions and communicate the same to Mr. Fordham for his opinion.

Dr. PARKER YOUNG thought it would be advisable to say that the Board, after consideration of replies from examiners, see no reason to make any alterations, also that a member of the Board was present when the papers were set. This was seconded by Miss PAGER and agreed upon.

A letter was read from the Clerk of the Privy Council with copy of a resolution from the Lutterworth Union complaining of unfairness and asking for the number of cases for a qualification to be reduced from twenty to seven.

Dr. PARKER YOUNG said the question was absurd, and would lead to retrogression if granted. A higher standard was needed, not a lower one. It was then agreed to send a refusal to the Lutterworth Guardians.

Further correspondence read showed that Dr. W. Rivers Pollock and Dr. W. Tate wished to resign as Examiners, which resignations were accepted, the President suggesting Dr. Hicks, of Guy's, London, as one substitute.

Dr. PARKER YOUNG objected, saying there were many men who would like the post and the requirement should be made known in the medical journals that each man might have a chance.

The PRESIDENT pointed out that it was wise to have some examiners in reserve or ready, that was his reason for suggesting Dr. Hicks.

This suggestion was adopted, and a letter from Dr. A. J. Wallace, saying a lady who had attended his lectures to his satisfaction six years ago, now wanted her certificate signed for such satisfactory attendance, but he was unwilling to do so as he had no knowledge of her present acquirements.

The PRESIDENT said this was a case of common law not to be adjudicated on by the Board, and the writer must go by written rules and his own conscience.

Dr. Eustace Hill, County Medical Officer for Durham, inquired by letter as to the extent of the exemption from supervision conferred by Rule E., Sec. 11, on midwives working in hospitals, workhouses, and poor-law institutions under a medical officer, as the Act included *all* midwives.

The PRESIDENT answered it was taken for granted that all medical officers at such institutions were resident and capable. It was highly desirable, but not practicable, that the position be more clearly defined.

Miss WILSON then moved: "That a Committee be appointed to consider the Board's penal proceedings generally and report thereon, as many trivial cases came up which could have been settled otherwise than at the meeting, and much time wasted."

Drs. Boxall, Roberts and Parker Young were therefore appointed as a Committee to inquire further and make suggestions.

The important question of rescinding a motion came up again, when Miss WILSON moved: "(1) That the resolution of the Board of November 23rd, refusing the application of the Secretary of the Cheltenham District Nursing Association for an extension of time for signing the schedules for the February examination in the case of four nurses now being trained by the Association be rescinded," saying that Cheltenham had fixed their dates before the alteration of dates by the Board. That the women would have fulfilled the required time all but two days and would lose appointments ready for them after the Examination, as the Cheltenham nurses were in high repute for their excellent training and rarely failed to pass.

Dr. PARKER YOUNG had much pleasure in seconding the motion. It would be a gross act of injustice to refuse.

Dr. DAKIN inquired if, legally, it could be done.

The PRESIDENT answered it could not, and they would land themselves in a difficulty by acceding.

Dr. PARKER YOUNG remarked it was not a question of formula but an act of justice.

Dr. DAKIN objected, saying that hundreds of other women might take this as a precedent and apply.

Dr. PARKER YOUNG replied that two wrongs did not make a right, whereupon

Dr. DAKIN asked if he found any more cases could he promise them the same "justice"?

The PRESIDENT concluded the discussion by saying that as they were going to drive a coach and six through an Act of Parliament, Dr. Dakin had better get any more through before the gap closed. The Cheltenham authorities had been told once it could not be done; now they were going to grant the request. He, himself, though sympathising with the applicants, must vote against the Resolution.

Dr. Dakin also voted against it, but the same was passed, and intimation to that effect sent to Cheltenham.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, January 28th, 1906.

TREATMENT OF JAUNDICE.

THE treatment of the different forms of icterus depends naturally on the cause, but at the beginning the treatment should be in every case symptomatic.

Milk regime increases diuresis and diminishes the toxins of the intestinal tract. About three quarts, says Prof. Huchard in an article on the subject, should be given daily mixed with alkaline water. Patients should not be forced to take too much milk, as frequently it is not well digested. A slight laxative is better than a drastic purgative, which weakens the patient. Numerous authors prescribe calomel, but neither Dr. Huchard nor M. Chauffard recommend it. According to these authorities adult persons support it badly; it could give rise to phenomena of mercurial intoxication. As to intestinal antiseptics, naphthol, betol, salol, they irritated the organism. Moreover, they take from the tissues the mineral salts which, constitute them, sulphur, potash, &c., and thus demineralise the tissues.

Internal antiseptics by naphthols is one of the greatest errors of the present time. Cold enemata (one quart

morning and evening) may be given and retained five or ten minutes; they produce diuresis, increase arterial tension, and empty the portal vein. In case of colic the enema should be given warm instead of cold.

The morning laxative might be continued eight days and suspended eight days, and so on. During the period of rest benzoate of soda at the dose of 15 grains at mid-day and the same amount at six o'clock in the evening in Vittel water should be prescribed; it acts as a stimulant to the hepatic secretion.

When the icterus is prolonged without much improvement other symptoms set in, and notably pruritus, which causes considerable inconvenience. In such cases, the treatment must be frequently changed to content the patient, for a sovereign remedy is not to be found in the arsenal of therapeutics. Alkaline baths of ten minutes' duration, warm shower baths, lotions with spirits of camphor (1-4), sublimate (1-2000), ichthyol (1-100), chloral (20-1000), give some relief. After the lotion the parts should be powdered with:—

Menthol	10 grains.
Talc	3 ounces.
If the itching persists, paint the region with		
Glycerine	2 ounces.
Chloroform	4 drachms.

If the jaundice shows no sign of abating a calculus is the probable cause, and Vichy treatment may be ordered, or perhaps surgical intervention may be necessary.

In cases of tumour an operation is useless. Where signs of grave icterus are present, two quarts of milk should be given daily, and each morning a purgative enema, followed by an hour later an enema of salt water (1-100).

Agitation is relieved by enveloping the patient morning and evening in sheets steeped in warm water (100° F.) and wrung out. Opothropic treatment might be tried with a chance of success. Dr. Malescopulo, of Alexandria, obtained several cures of infectious icterus by means of hepatic extract.

HYDROCELE.

The classical treatment of hydrocele with injections of tincture of iodine is very painful, and in certain debilitated subjects have produced very grave results. Prof. Teissier recommends the following, which he affirms is painless and free from accidents:—

Orthoform	30 grains.
Proof spirit	6 drachms.
Distilled boiled water	1½ ounces.
Caustic potash	1-32 grain.

The addition of the caustic potash is to obtain a perfectly limpid solution.

After evacuation of the serosity of the hydrocele, and leaving the needle in place, the above liquid is injected, and the parts malaxed for a few moments. The liquid is then withdrawn and the usual tincture of iodine is injected. At the end of ten minutes this solution is again removed and the needle withdrawn. A plug of cotton wet with collodion seals up the wound. The anæsthesia produced by the orthoform lasting a long time by reason of the slow absorption of the drug, the patient experiences no pain during nor after the injection, although the inflammatory reaction is produced as usual.

The solution of iodine which M. Teissier employs is as follows:—

Tincture of iodine	1 ounce.
Distilled water	1½ ounces.

CHAPPED HANDS.

The following will be found very effective in this uncomfortable condition of the hands:—

Glycerine (pure)	1½ ounces.
Peruvian balsam	4 drachms.
Salicylate of soda	1 drachm.
Rose water	6 ounces.

used as a lotion morning and evening.

GERMANY.

Berlin, January 28th, 1906.

At the meeting of the Berlin Society for Psychiatry and Nerve Diseases, Hr. Oppenheim showed preparations from a case of

CEREBELLAR TUMOUR.

He spoke of the difficulties of operation in such cases, and of the great changes set up in the brain by them.

The case was that of a man *æt.* 38, who was attacked in August, 1904, with noises in the right ear and deafness, and later on giddiness. It was not until July last that more grave symptoms appeared—paræsthesia of the right half of the face, spasms and loss of visual power, nystagmus on looking to the right, slight optic neuritis, also slight cerebellar ataxy, and paresis of the right facial nerve.

Diagnosis.—Tumour in the region of the right side of the pons.

An operation was performed by Hr. Borchardt at two sittings. The last in December last when large masses of the tumour were removed. Some portions of cerebellum were also taken away. The patient died in a state of coma the next day. The growth was very extensive, the medulla oblongata, being forced a good deal to one side.

Hr. Mosse showed a case of

PARALYSIS AGITANS.

remarkable for its rapid advance. The hands were blue, and there were jerky movements of the vocal cords from rigidity of the laryngeal muscles.

Hr. Henneberg spoke on

CYSTICERCUS,

as affecting the brain. After going over the symptomatology and pathological anatomy, he went on to say that cysticercus was still comparatively frequent in Berlin. One death took place generally every year in the Nerve Klinik of the Charitee. Cases in which it was doubtful as to whether the disease existed were not so rare.

He reported the following case:—A woman, *æt.* 22, during pregnancy had pains in the stomach, constipation, vomiting, a feeling of constriction in the neck, headache and giddiness, distress and delirium. On admission there was some delirium, optic neuritis, paresis of the abductens of the left facial, the hypoglossus, pain in the neck, static ataxy, loss of patellar reflex, no lymphocytosis of the cerebro-spinal fluid, no increase of pressure, no fever. The autopsy showed cysticercus in the right thalamus. The *foetus* was macerated, there was no hydrocephalus.

He characterised the case as a pseudo tumour cerebri and assumed an auto-intoxication, but he could not exclude an action on the part of the cysticercus with certainty. The frequency of epilepsy and psychosis in cysticercus had been over-estimated. These were often due to accompanying conditions. Epilepsy of childhood from cysticercus was sometimes very pernicious. At the base of the brain the cysticercus often took a racemose form and led to chronic fibrous leptomeningitis. He brought forward five cases of vasa cysticercus. Ventricular cysticerci arose from the choroid plexus. In consequence of the stream of fluid they were most frequent in the fourth ventricle. Brun's symptoms were not always present in these cases and it could not be attributed to change of position in the cysticercus. A man *æt.* 38 had headache, vomiting, giddiness, noises in the ears, hyperæsthesia, hysteriform leptoform attacks. Suddenly paralysis of respiration, and death. Autopsy: A moderate degree of hydrocephalus, a perfectly free cysticercus, the size of a cherry stone in the fourth ventricle. The treatment could be only operative—division of the worm, and this had not yet been carried out.

SPIROCHÆTA PALLIDA.

Volk and Landsteiner exhibited preparation of *spirochæta pallida* in tissue prepared after Levaditi's method.

AUSTRIA.

Vienna, Jan. 28th, 1906.

EXTIRPATION OF LARYNX.

ALBRECHT exhibited a patient on whom Hochenegg operated for carcinoma of the larynx by extirpating the entire larynx. The patient is now well and with the aid of an artificial larynx can make himself perfectly understood. He is able to converse with others in a neighbouring room with closed doors. He is a surveyor and measurer, and can call out on the field with intelligence and energy. In cold weather, to prevent rapid change in the trachea he can breathe from the pharynx by means of an india-rubber tube.

Exner suggested a modification of the instrument, which would enable the patient to whisper or alter the tone at will, and which could be managed by the lips.

TUBERCULOSIS OF SKIN IN APES.

Kraus again informed the meeting that he had conducted other experiments on the *Macacus rhesus* with the same results as in his previous reports. He believes with Kren that it is quite possible to inoculate the monkey with cutaneous tubercle. He has now performed this operation many times, with direct inoculation from the human skin as well as by pure cultures of the tubercle bacilli. He has also obtained similar results with different species of "Provenienz Tuberculosis" as well as with *perl sucht bacilli* on the site of inoculation within 8 or 10 days after inoculating which, can be distinguished from genuine tuberculosis as the latter does not appear within 16 days after the operation.

Paltauf wished it to be distinctly understood that the identity of these two bacilli, the rinder and human, did not destroy the proof that they were different species of bacilli, neither did it disprove the opposite.

LYMPHANGITIS AND LYMPHADENITIS.

Khautz next demonstrated a girl, *æt.* 12, with tuberculous lymphangitis and lymphadenitis cubitalis in the left arm, which suddenly appeared half a year ago after cutting her thumb with the bread knife. No signs or trace of tubercle can be discovered in any of her ancestors, leaving the source of infection a mystery. All the other organs are perfectly healthy. The primary wound has left a morbid growth about the size of a two shilling piece over the extensor surface of the thumb, which dermatologists have diagnosed as tuberculosis verrucosa cutis. In one of these softened glands taken from above the elbow fourteen days ago the tubercular bacilli were found, but in small quantity. The infected lymph vessels are knotty, lying like strings of beads along the sulcus of the bicipitalis internus as well as the flexors of the fore-arm, down to the infected thumb over which the skin is movable, and in no way reddened.

THORACIC DEFECTS.

Ranzi showed the members a boy, *æt.* 9, with defective ribs from the second to the sixth; there was absence of the sterno-costal portion of right pectoralis major; partial defect of the pectoralis minor, serrati, hypoplasia of the right scapula brachydactylia, syndactylia and convex scoliosis. In the second case, 6½ years, there was an absence of ribs on the left side from the seventh to the eleventh, with an elevation of the right scapula and right convex scoliosis.

Berlin Doctors' Incomes.

THE Medical Chamber of Berlin has recently issued some statistics regarding the incomes of local medical practitioners. It would seem that no fewer than 1,322 physicians in Berlin in regular practice do not reach £250 per annum. The average income for a Berlin medical man is £450. In the upper regions of the profession fifteen have an income of £2,500 to £3,000, thirteen from £3,000 to £3,500, three from £3,500 to £4,000, six from £4,500 to £5,000, four from £5,000 to £6,000, five from £8,000 to £9,000, and one each with incomes £13,000 and £16,500.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

WOMEN GRADUATES AND PARLIAMENTARY FRANCHISE.—In view of the fact that voting papers for the coming contest for the Parliamentary representation of Edinburgh and St. Andrews Universities have been sent out only to male graduates, a meeting of the women graduates of these universities was held in Edinburgh on January 27th. A large number of graduates from all parts of the country were present. The proceedings were private, but we understand that it was unanimously decided that immediate steps should be taken to test the legality of the action of the authorities in declining to supply ballot papers to women. It seems that the construction of the statute bearing upon university representation is in this respect by no means clear; indeed, when the Act was passed many of the universities did not confer degrees upon women, and in any case the present is the first contest in which any considerable number of women have been on the roll of members of the General Council. The matter is of very considerable general interest and importance, as should it be decided that female graduates have the same right as males to vote for a University representative in Parliament it would mean the introduction among a limited section of the community, of female suffrage.

BELFAST.

BELFAST HOSPITAL FOR SICK CHILDREN.—The annual meeting of this charity was held last week, and a good year's work was put on record. In the intern department, 841 cases were treated; the annual cost per bed was £50 6s. 8d., and the average cost per day 2s. 3d. The cost of the keep of the household and children per day is less than 7½d. per individual. There were 39 deaths in the wards. The operations numbered 366 in the intern and 341 in the extern department. In the out-patient department, 5,196 new cases were seen with a total attendance of 16,545. The secretary of the Board stated that the question of patients being paid for was very thoroughly investigated by a large committee of the Board and lady representatives. A large number of parents and others were interviewed, and after mature consideration it seemed to be conclusively proved that there was no abuse of the charity, and that only an infinitesimal minority of the parents could contribute anything to the funds. The Dean of Belfast, in speaking at this meeting, made some excellent observations on the necessity of having a united collection for all the hospitals of the city on a given Saturday and Sunday, and not, as at present, each hospital taking care of itself. This matter has often been mentioned, but no step has yet been taken to bring the end in view any nearer.

LONDONDERRY DISTRICT NURSING ASSOCIATION.—The Duchess of Abercorn presided at the annual meeting of this charity last week. The report showed that during the year 1,356 cases had been attended, and 24,136 visits paid.

LETTERS TO THE EDITOR.

SPECULATIVE ACTIONS AND MEDICAL WITNESSES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Whilst agreeing with you that Dr. Miller, of Putney, is to be congratulated upon the success of his action against a solicitor for recovery of fees for attendance in Court as a medical witness, I am afraid that the success is not so far-reaching as is imagined by those who have merely read the newspaper report of the case. In the case it was amply proved that there was an arrangement between the solicitor and his client that the former was to pay all expenses

in the original action against the Metropolitan Asylums Board, and that the client was not to be liable for any costs. It was this important point which enabled Dr. Miller to recover his fees from the solicitor who had thus practically made himself liable for the costs in the action. It must therefore not be taken for granted that in any action brought by a "man of straw" so to speak, that the solicitor would be liable and could be successfully sued. It is only when legal proof is available to convince the Court that the solicitor has accepted the liability in this respect that a successful issue for the recovery of the fees from him can be gained. I am afraid that in the majority of instances such evidence would not be available, and that therefore Dr. Miller's case, although decided upon sound law, cannot be taken as extending the liability of a solicitor except under the very special circumstances of the individual action concerned.

I am, Sir, yours faithfully,

A. GEORGE BATEMAN, M.B.,

Gen. Sec. Medical Defence Union.

Medical Defence Union, 4 Trafalgar Square, W.C.,
January 24th, 1906.

THE APOTHECARIES' HALL AND THE PHAR- MACEUTICAL SOCIETY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am more than amazed to find that the MEDICAL PRESS, which usually advocates the rights of the Irish Medical Corporation, has allowed itself to be led into such a serious error as to state that whereas formerly apothecaries' assistants were required to serve a seven years' apprenticeship, now they get their certificates after three months' training. The fact is, that the regulations require at least two years apprenticeship at present. In the middle of the last century (1852) it was reduced to three years, and previous to that time the seven years was insisted on for the apothecary keeping open shop, whilst his assistant, foreman or shopman, was required to serve five years. I venture to think that the medical profession does not realise how it will be hit if the Pharmaceutical Society of Ireland succeed in their pretensions. Already the British Society has made a mere tool of the Medical Council, and hypnotised it into declaring that if a medical practitioner should keep a pharmacy, and allow his assistant to sell a drachm of precipitate powder, the practitioner will be adjudged to be guilty of infamous conduct and will be struck off the Medical Register unless the assistant happens to be a fully qualified chemist.

Now the law in Ireland is different and still more drastic. It is an offence in this country not only to sell a poison, but to compound a medical prescription; and hence it follows that if the Pharmaceutical Society succeed in upsetting the validity of the certificate of the assistant, which has been issued by the Apothecaries Hall for over one hundred years, every medical practitioner in Ireland who allows anyone but a pharmaceutical chemist to compound his prescriptions will be at the mercy of any common informer who may choose to report him to the General Medical Council, and that body will be bound, according to their own ruling, to strike him off the Register.

To realise the colossal cheek of the effort of the Pharmaceutical Society to discredit the apothecary assistant we must remember that the number of qualified assistants on the Society's own books (excluding pharmaceutical chemists) is only 37, and their argument is that these must be considered the only qualified men to supply the 1,600 pharmacies, drug stores, and private surgeries in Ireland. The pharmacists say that the Act of 1791 compelled the Apothecaries' Hall to examine every assistant in every medical hall in Ireland from 1791 to 1875, but they insist that every certificate given during all that time was invalid unless it was such a one as would have enabled the holder to get on the Medical Register.

So monstrous are the claims of the Pharmaceutical

Society, or rather of Mr. Wells, the ex-president, that one would think they need but be brought into court to be quashed. But the Society has plenty of money and seems inclined to spend it in law, whilst the Apothecaries have not the same lust for the Law Courts. Happily, however, they have in evidence what they lack in litigiousness. They have the charter granted to the Dublin Society of Apothecaries in 1746, in which assistants are given very ample powers. They have registers entitled "Register of Assistants or Journey-men, 1796 to 1828." They have record after record in their minutes from 1793 showing that persons who were refused the certificate to keep open shop as apothecary were given a certificate enabling them to act as assistant to an apothecary. They have proof that so long ago as August 9th, 1859, they moved that when a candidate appealed against their decision to the College of Physicians and the appellant was successful he was granted a certificate to enable him to act as an assistant, but not to use the title "apothecary," and they have the most ample proof of the gradual differentiation and development of the examination required according as the candidate desired to act as a mere journeyman assistant—or as a journeyman further certified to keep open shop—which, in course of time developed into the triple qualification of the present day.

I am, Sir, yours truly,
J. C. McWALTER.

Dublin, Jan. 22nd, 1906.

[The statement to which Dr. McWalter objects was made in the discussion to which we referred, and had passed without contradiction. We quoted it merely as an illustration of the changes that have taken place in education during the past century, and not as a reflection on the Apothecaries' Hall. The main point is, as we said, one to be settled by lawyers.—ED.]

SANITARY ADMINISTRATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As one of the public taking part in sanitary administration I thank you for the article in your issue of January 24th. My mild astonishment at some of the remedies for existing evils put forth from time to time by the very able member of the *Times* editorial staff, who discusses these subjects, has not been diminished by the fact that he is mostly so well informed and that his writings seem to show that he is a member of the medical profession. Is it not quite evident that if authorities were compelled to co-opt a few sanitary experts these would be outvoted whenever a majority of reactionaries were present on the Council and on the other hand that such experts would not be necessary in any place where a sufficiently strong public opinion prevailed? Without public opinion to appeal to the experts would become as powerless as the medical officers now remain. Then again, the proposal to give these last named officers fixity of tenure in their appointments would form a far from complete remedy for their present virtual impotence. The authorities would continue to select candidates and fix the amount of their remuneration. By cutting down the stipend of the medical officer to the lowest possible figure they could make tolerably certain that none save such as recognised themselves to be failures in their profession would apply. Such men would not be as a rule, difficult to intimidate; and the knowledge that any increase in pay and the prospect of a pension for long faithful service would still depend upon the authority would probably suffice to make them as subservient as the authority could desire. The only cure for existing evils is that to which you point—namely, improvement in the personnel of governing bodies; and this can be brought about only by the development of local patriotism. The remedies proposed by the *Times* would form a step towards bureaucracy, and there can be no doubt bureaucratic administration if only tolerably honest, would in most places be of far greater advantage to the public than the present pseudo-democratic method. Gambetta once said, "You cannot

have a republic without republicans," and in the same way you cannot have true "government for the people by the people," when the majority of the public refuse to do their duty as citizens—that our citizens nowadays decline to do their duty, is as you suggest, one of the many ugly signs of the times.

I am, Sir, yours truly,
SANITARIAN.

January 26th, 1906.

OBITUARY.

DR. H. S. PURDON.

THE death of Dr. Henry Purdon removes a figure well known for many years in Belfast, where he practised as a dermatologist, and also acted as medical inspector under the Factory Acts. Dr. Purdon was a little over sixty, and was the eldest of the second generation of medical men of the name in the town. His father, Dr. Charles Purdon, and his uncle, Dr. Henry Purdon, were leading practitioners forty or fifty years ago; two of his brothers are in practice—one in the city and one in England, and two of his sons have entered their father's profession, one of them following him at the Belfast Skin Hospital.

Dr. Purdon studied in Belfast, then in Dublin, Glasgow, and London. For many years he was on the staff of the old Royal Hospital, but later confined his attention to the Skin Hospital and his Factories work. He was a singularly quiet and retiring man, with few intimate friends except those of his boyhood who remained here. He was known to be in bad health for some time past; the cause of death was organic obstruction of the bowel.

DR. JOHNSON, OF BRADFORD.

DR. JOHNSON was an Ulsterman, educated at Queen's College, and a graduate of the Queen's University. Though settled in Bradford for more than thirty years he kept up an intimate connection with his native land, and many a successful practitioner in Belfast and elsewhere has begun life by passing from Queen's College, Belfast, to act as assistant to Dr. Johnson. He was a bachelor, and two of his great interests in life were the Bradford Medico-Chirurgical Society, and the Bradford Rifles, of which for twenty-two years he was surgeon, retiring with the rank of Surgeon-Lieutenant-Colonel about three years ago. He was an excellent shot, and wore the Volunteer medal for long service. He was a great personal favourite with a large circle of friends.

DR. E. J. HAWKES, J.P., OF RAMSGATE.

WE regret to record the sudden death, on the 22nd inst., of Dr. Edward John Hawkes, J.P., of Ramsgate. He had recently recovered from a somewhat severe indisposition, and had for some days been actively pursuing his professional duties. As late as the morning of his death he occupied a seat on the Bench at Ramsgate in his capacity as a borough justice. Later on in the day, he passed away as the result of the breaking of a blood vessel. Dr. Hawkes, who was sixty-four years of age, came of an old Cornish family. He studied medicine at the Bristol Medical School and at Edinburgh. For some years he practised at Hastings, and later took charge of the South Devon Hydropathic Establishment for three years. He came to Ramsgate in 1886.

DUNCAN MACGILVRAY, M.B., C.M.GLASG.,
L.F.P.S.

WE regret to announce the death of a well-known Glasgow practitioner, at the early age of forty-seven. Infection caught in the course of his ordinary work developed into blood poisoning, and a vigorous career was speedily brought to a painful termination. He was undoubtedly a victim to the faithful performance of a duty wherein danger lay. He was M.B. and C.M. of the University, and also a licentiate of the local

Faculty. He was president of the Glasgow Southern Medical Society, and chairman of the Glasgow Medical Club. He was unmarried, and is survived by his mother and sisters.

**WILLIAM WINGATE SAUL, M.D., HEIDEL.,
M.R.C.S. ENG., OF LANCASTER.**

SURGEON-COLONEL WINGATE SAUL, who for over a quarter of a century was one of Lancaster's leading physicians and public men, died on the 22nd inst., aged sixty-four. Deceased was connected with the Duke of Lancaster's Yeomanry for twenty-two years, and served under six commanding officers. He was the founder of the Lancaster St. John Ambulance Association. For nearly twenty-five years Colonel Wingate Saul was surgeon to the civil and military prisons. For some years the deceased was a member of the Central Committee of the Royal Albert Asylum at Lancaster.

**SURGEON-MAJOR-GENERAL WILLIAM
FREDERICK DE FABECK, M.D., M.R.C.S., Eng.**

THE death is announced of Major-General de Fabeck, late of the Indian Medical Service, who died at his residence in London on January 18th. He entered the Army Medical Department in 1855, and served both in the Crimean campaign and in the operations for the pacification of Northern India following on the Mutiny. After holding many military medical appointments and also district civil surgeoncies in India, he was selected in 1886 for the post of deputy-surgeon-general for the Nagpur force and the Central India regiments. Four years later he became surgeon-general with the Government of Madras, and continued to hold executive charge of the medical service in the presidency until his retirement in May, 1894.

SPECIAL ARTICLE.

POPULATION RETURNS (IRELAND).

THE Report of the Registrar-General for Ireland for the year 1904 has recently come to hand, nearly twelve months from the termination of the period to which it relates. It is difficult to see any reason for this long delay, as the Report does not contain any novel features, and the entire compilation might be performed in fewer weeks than it has taken months.

The estimated population of the country is still decreasing—the decrease shown in the present Report being some twelve thousand, as compared with over eighteen thousand in 1903. As usual, this decrease is entirely due to emigration, the births showing a healthy preponderance over the deaths. The actual numbers are—births, 103,811; deaths 79,513; emigrations, 36,902. That is to say, the natural increase of population of 24,298, was overbalanced by the number of emigrants, resulting in a decrease of 12,604. To this, there should be a slight set-off from immigration of which no official record is taken. In the face of these dismal facts it is some little consolation to learn that the emigration rate per 1,000 of the population is at present, and has been since 1900, on the decline, though the actual fall is very slight. It is to be feared that the present marked depression in trade will show itself in the next emigration tables by a distinct rise. It is perhaps a sign of increasing prosperity that the marriage-rate has, during the past twenty years, shown a consistent upward trend, and now stands at its highest point, 15.22 per 1,000 of the population. The number of persons married under age is very small, being only 1.42 per cent. of the men married, and 6.32 per cent. of the women. Of those married under age the highest proportion of both men and women was in the province of Ulster, and the percentage in Ireland as a whole was much less than in either England or Scotland.

Of the children whose births were registered during the year, only 2.5 per cent. were illegitimate. The percentage in Ulster was 3.4, in Leinster 2.6, in Mun-

ster, 2.2, and in Connaught 0.7. These returns compare favourably with the returns of most other countries.

In the table of the causes of death, tuberculous diseases still stand easily first, with a total of 12,694 deaths, yielding an annual rate of 2.9 per 1,000 persons living. This is the maximum rate yet reached, and it is deplorable that whereas the death-rates from tubercle in England and Scotland have declined almost by half in the last forty years, the rate in Ireland has gradually increased.

The rate, too, which represents the total deaths from malignant disease, was the highest yet recorded for Ireland, 0.69 per 1,000.

The Report has been carefully prepared, and contains a mine of information for the statistician and the medical man. We notice that the Registrar-General gratefully acknowledges his indebtedness to Dr. Ninian Falkiner, Medical Superintendent of Statistics.

NEW BOOKS AND NEW EDITIONS.

THE following have been received since the publication of our last list:—

- J. B. BAILLIÈRE ET FILS (Paris).
Mouches et Choléra. By A. Chantemesse and Frédéric Borel, Pp. 96.
- JOHN BALE, SONS AND DANIELSSON, LTD. (London).
Indigestion: Its Causes and Treatment. By Fernandez Clarke, L.S.O., L.R.C.P., &c. Pp. 85. Price 2s.
- Patent Foods and Patent Medicines: Two Lectures by Robert Hutchison, M.D., F.R.C.P. Second Edition Pp. 47. Price 1s. net.
- A. AND C. BLACK. (London).
The Englishwoman's Year-Book and Directory, 1906. Edited by Emily James. Pp. 402. Price 2s. 6d.
- CHAPMAN AND HALL, LTD. (London).
An Introduction to Volumetric Analysis. By A. Jamieson Walker, Ph.D. (Heidelberg), B.A., and Owen E. Mott, Ph.D. (Heidelberg). Pp. 64. Price 2s. 6d. net.
- ARCHIBALD CONSTABLE AND Co., LTD. (London).
Lectures on Tropical Diseases, being The Lane Lectures for 1905. By Sir Patrick Manson, K.C.M.G., M.D., &c., &c. Pp. 230. Price 7s. 6d. net.
- HENRY J. GLAISHER. (London).
Oliver Wendell Holmes and The Contagiousness of Puerperal Fever, by C. J. Cullingworth, M.D., F.R.C.P. With Portrait. Pp. 35. Price 1s. 6d. net.
- T. C. AND E. C. JACK. (Edinburgh).
The Edinburgh Stereoscopic Atlas of Anatomy. Section 3. Edited by David Waterston, M.A., M.D., &c., &c., Price 25s. net.
- MACMILLAN AND Co., LTD. (London).
A Handbook of Climatic Treatment, including Balneology. By William R. Huggard, M.A., M.D., &c. Pp. 536. Price 12s. 6d. net.
- A Text-Book of the Diseases of the Ear, Nose and Pharynx. By D. B. St. John Roosa, M.D., LL.D., and Beaman Douglass, M.D. Illustrated. Pp. 621. Price 12s. 6d. net.
- YOUNG J. PENTLAND. (Edinburgh).
The Edinburgh Medical Journal. Edited by Alexis Thomson, M.D., L.R.C.S. Ed. and Harvey Littlejohn, M.B., F.R.C.S., Ed. New Series, Vol. XVIII. Pp. 576.
- W. B. SAUNDERS AND Co. (London).
A Text-Book of Physiology for Medical Students and Physicians. By William H. Howell, Ph.D., M.D., LL.D. Illustrated. Pp. 905. Price 18s. net.
- A Manual of the Diseases of Infants and Children. By John Rubrah, M.D. Illustrated. Pp. 404. Price 10s. net.
- THE SCIENTIFIC PRESS, LTD. (London).
Surgical Instruments and Appliances used in Operations. By Harold Burrows, M.B. Lond., B.Sc., &c. Pp. 96. Price 1s. 6d. net.
- SMITH, ELDER AND Co. (London).
Bodily Deformities. Vol. I. By the late E. J. Chance, F.R.C.S. Eng. Edited by John Poland, F.R.C.S. Eng. Second Edition. (in 2 vols.) Pp. 315. Price 6s. net.

WALKER'S ARBORETA DIARY forms a most convenient diary with detachable sheets. The cover is of solid leather, and may be had of various qualities and prices. There is provision for cash accounts and other medical and general memoranda. Altogether it is an excellent diary. As to the medical case-book, constructed on the same plan, it is one of the best we have hitherto seen. It has a temperature chart and diagram of chest with spaces for name, age, family, and personal history, notes of case, and so on, all on detachable sheets, which can be filed separately. It is the very thing for an honorary medical man attending hospital to take notes of rare or interesting cases, or for the general practitioner or consultant to keep a systematic record of bedside memoranda. Published by J. Walker and Co., Warwick Lane, London.

MEDICAL NEWS IN BRIEF.

A Herbalist fined under the Pharmacy Act.

AN action was brought by the Council of the Pharmaceutical Society of Great Britain, for whom Mr. J. B. Marsh appeared to recover £5, under the Pharmacy Act of 1868, from Thomas B. Fahy, herbalist, of 139, Golden Hillock Road, Small Heath.—Mr. Marsh explained that the action was brought to recover the penalty imposed upon the defendant for having described himself as a chemist, whereas his name did not appear on the register which was kept by the Pharmaceutical Society. He believed there was a letter before the judge in which defendant admitted the offence, and undertook to pay the full penalty by £1 per month. He asked for judgment on those terms.—This was entered accordingly.

Patient Sues Medical Man for mistaken Diagnosis of Enteric Fever.

IT is alleged by Mrs. Hall, wife of a Brixton billiard marker, that Dr. Louis Stamm wrongly diagnosed her to be suffering from typhoid instead of influenza, that she was taken to Stockwell Fever Hospital for seventeen days, and that some of her goods were destroyed in a process of "disinfection." The sequel was a claim for £40 damages made in the Wandsworth County Court on January 24th, by Mrs. Hall, and her husband against Messrs. Burgess, Brock and Stamm, physicians and surgeons, for alleged negligence. Just before her illness, it appeared, Mrs. Hall had eaten a quantity of oysters. Two of the hospital doctors gave evidence that the symptoms were very suggestive of typhoid, and that Dr. Stamm's action was justified. Judge Russell said it was a case which ought never to have been brought. Dr. Stamm sent the woman to the hospital for proper treatment, and in return the plaintiffs had shown their appreciation by bringing an action against him. He gave judgment for the defendants, with costs on the "C" scale.

A New Prophylactic against Plague.

THE Local Government Board's medical department has issued a preliminary report, made by Dr. Klein, F.R.S., on a new prophylactic against plague, and it is hoped that his experiments will point the way to some more certain and uniform method than those at present in use.

The Gresham Lectures.

DR. E. SYMES-THOMPSON, as Gresham Professor, continued his course of lectures on the nervous system at the Gresham College on Friday last, and, in dealing with the question as to which kind of food was best for the maintenance of the nerves, said the whole matter rested upon the health of the individual. If a man was healthy he could get adequate nourishment from almost any kind of food. The particular foods best suited for the building up of the nervous system were those of a fatty nature, such as milk, cream, butter, eggs, and white meats. Where the digestion needs assistance, the nervous system benefited by one or other of the artificial nerve foods containing glycerophosphates, which was a particularly valuable, in fact, one of the most valuable, foods. He strongly deprecated the indiscriminate use of drugs, such as antipyrine, though it might be beneficial in certain cases when taken under the instructions of a medical man.

Colonies for the Feeble-minded.]

THE Royal Commission on the Care and Control of the Feeble-minded is continuing its sittings at Westminster, the evidence on Friday last being of an interesting and suggestive character. Dr. Nathan Raw, visiting medical superintendent at the West Derby

Union Infirmary, Liverpool, said that he thought defective children should be separated into two divisions—those capable and those incapable of education. The first should be under the control of the education authority, and the second taken charge of by the county councils, and either classed in special institutions or in the present county asylums. There was no difficulty in the case of adults obviously certifiable as insane, but for those on the border line the case was not so easy. Many cases had come under his notice of persons repeatedly convicted of offences who were not really responsible for their actions. Such people should be drafted off to proper colonies, where they could be under permanent detention, and made to lead a useful life. On a large scale these colonies might be made practically self-supporting. Dr. Thomas Jackson, late assistant medical officer of the Glamorgan and Notts Counties Asylums, urged the necessity for establishing a system of notification of cases of feeble-mindedness. It would, he said, be useless to insist that the parents of those afflicted should notify, as relatives rarely admitted that a kinsman was mentally unsound. For statistical purposes, it was necessary that proper notification should be instituted as well as on the score of economy. Idiots, imbeciles, epileptics, and others were repeatedly thrown on to the rates at a late period of their lives, when they were practically useless and incapable of any training.

Medical Society of London—The Lettsomian Lectures.

THE first of the Lettsomian Lectures (1906) on "Some Points in the Surgery of the Brain and its Membranes" will be delivered by Mr. Charles A. Ballance, M.S., F.R.C.S., Surgeon to St. Thomas's Hospital, and to the Hospital for Paralysis, on Monday next, Feb. 5th, at 9 p.m., the subject being "The Surgery of Meningitis."

Apothecaries' Hall of Ireland.

AT the January Medical Examination, W. Shaw-Stewart, passed in Chemistry and Junior Anatomy, and completed 1st Professional. J. E. McDonogh passed in Chemistry and Physics, M. Moody passed in Senior Anatomy, and completed the 2nd Professional. J. Gillespie passed in all subjects and completed the 3rd Professional. D. J. Boyle and J. Hartigan passed in Pharmacy and completed the 3rd Professional. M. J. Murphy passed in Hygiene and completed the 3rd Professional. M. Moody passed in Hygiene, J. Gillespie and J. Hartigan passed in Medicine, Surgery, Midwifery, and Ophthalmology, and completed the 4th (final) Professional. D. J. Boyle passed in Medicine, Surgery, and Midwifery.

The Diploma entitling the holder to practice Medicine, Surgery, Midwifery and Pharmacy, will be granted to the following candidates—J. Gillespie and J. Hartigan.

Conjoint Examinations in Ireland.

CANDIDATES have passed the Second Professional (January) examination as undernoted:—W. M. Woods (with Honours), J. J. Barry, G. Collins, A. Cullen, C. T. Cullimore, J. Farrell, J. A. J. Flannery, G. W. M. Gleeson, C. Greer (Victoria, Australia), C. Macauley, H. E. M. Miles, D. McCormack, F. J. McManus, T. J. O'Donoghue, G. Patton, H. B. Sherlock, C. Stringer.

Candidates have passed the Final Professional (January) Examination as undernoted:—Leopold ApArthur Andrews, Charles Joseph Rea Clarke, Frederick O'Dowda Fawcett, Thomas A. Flynn, Cormac Gordon, Michael Joseph Christopher Kennedy, Ernest Henry Marcus Milligan, Richard Vincent Murphy, John McQuillan, Benjamin Alexander Odium, Cornelius William O'Keeffe, Caroline Elizabeth O'Mear, and William Roche.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for the MEDICAL PRESS AND CIRCULAR.
RECENT MEDICAL LITERATURE.

The Elimination of Chlorides in Nephritis.—Miller (*Journal of the American Association*, Dec., 1905) gives the results of his experiments in investigating the action of chlorides on the kidney functions in cases of nephritis. Working on the lines of previous observers, he made observations on the urine in cases of acute and chronic parenchymatous nephritis. The patients at first were kept on a dietary almost free from salt, and then, the effect was noted of the administration of large quantities of sodium chloride. The first three days the patient had merely the chlorides contained in his food; the following three days he received daily an additional 10 grammes of NaCl; then the three following merely the chlorides contained in his food. The total urine for each of the three day periods was noted; the total chlorides in each period; the grammes of chloride retained in the body when extra salt was given, and the percentage of it in the urine during each period. Two cases of acute nephritis were examined and six of chronic parenchymatous nephritis. In all there was a visible increase in the œdema during the saline administration, one patient gaining 3 lbs. during the taking of the chloride, and losing it when the salt was discontinued. In all there was a chloride retention, the urine was diminished, and the amount of albumin markedly increased. Two patients developed uræmic symptoms. In two patients suffering from uræmia, following administration of the salt the urine was lessened—one case from 500 to 240 c.c.—and scarcely any of the extra chloride appeared in the urine. The œdema was decidedly increased, and the patient's condition worse. Four patients without apparent heart or kidney trouble were tested as controls. All of these showed a chloride retention about equal to that of the milder cases of nephritis. In these the quantity of urine was not diminished. No œdema resulted. Assuming that the salt was absorbed from the intestinal tract, it must have remained in the tissues, associated with sufficient water to maintain the proper dilution—i.e., the patient had an undemonstrable œdema. The tissues of the nephritics were already water-logged so that any increase in œdema was readily observed. In support of this view one of the patients was weighed daily and showed an increase of 2½ lbs. during the administration of the chlorides. From his observations Miller deduces that both in normal subjects and in cases of moderate nephritis there is a chloride retention when large quantities of NaCl is given—i.e., only a small quantity of the extra salt appears in the urine, but in advanced cases of nephritis, there is a very marked impermeability of the kidney to sodium chloride; that during administration, the patient gains in weight, the œdema becomes more marked, the albumin increases and symptoms may develop resembling uræmia. From a therapeutic standpoint in cases of nephritis he suggests that common salt should be avoided as it causes not only water retention, but, by increasing the osmotic pressure of the blood, lessens perspiration, and the amount of water lost by respiration. Two grammes of sodium chloride are sufficient for the animal economy. Disappearance of œdema and general improvement in cases of nephritis have been noted on the following dietary; meat 400 grammes; potatoes, 1,000 grammes; sugar, 100 grammes; butter (unsalted), 80 grammes; fluids, 2,500 c.c. This diet contains only 1.5 grammes of chloride. The use of subcutaneous injections of salt is contra indicated as it may favour the development of uræmia. D.

Treatment of Attack in Spasmodic Asthma.—Morrison (*Lancet*, Dec. 1905) describes his treatment of the attack in spasmodic asthma as carried out frequently and always with success. The principle of the treatment is to aid the patient to empty the chest of

air. With one hand on the back and the other on the front of the chest, Morrison empties it at the end of each inspiration. After several manœuvres of this kind relief is given. Even in old people with stiffened chests he has found compression by one hand over the thorax and the other over the epigastrium, the lower ribs, or preferably over the right hypo-chondro-epigastric region, give relief from the thoracic anxiety attending the fixation of the chest, which is chiefly inspiratory. It is unnecessary to give any drugs. D.

Therapeutic Value of Lecithin.—Fritz Levy writes (*Berlin Klin. Woch.*, Sept., 25th, 1905, No. 39), on the medicinal uses of lecithin and of lecithin containing food stuffs. He points out that previous observers had noted an increase in red cells and in hæmoglobin when pure lecithin was administered, and then details the result of his own experience with lecithoyen, a lecithin-containing cocoa. Three or four teaspoonfuls of the powder were given daily, mixed with milk, to five patients, and the clinical results were accurately noted day by day. All of these patients were suffering from anæmia, and in all of them he observed a rapid increase in the number of red cells and in their hæmoglobin contents, and a corresponding increase in body weight. At the same time there was an increase in the output of urinary phosphates. From this he concludes that lecithin containing substances are absorbed as readily as pure lecithin, and are of equal therapeutic value. M.

Miliary Aneurysms of Stomach.—Hæmorrhage resulting from small miliary aneurysms in the gastric mucous membrane are very rare. Up to this only six cases have been recorded in the literature. Hirschfeld (*Berlin Klin. Woch.*, 1905, No. 22) now describes a seventh in a man, æt. 38. The patient first suffered from bleeding in 1883, and the hæmorrhage recurred thirteen times in the course of twenty years, the last proving fatal. At the autopsy all the organs, including the liver, appeared to be perfectly healthy, but close observation revealed the presence of multiple miliary aneurysms in the gastric mucous membrane, many of which were only to be detected by the aid of the microscope. It appears probable that many cases of obscure hæmatemesis may be due to this condition, especially in individuals of a hæmophilic tendency. M.

Carcinoma of the Thoracic Duct.—Schwedenberg (*Virchow's Archiv*, Bd., 181, H2) reviews the literature dealing with this subject and comes to the conclusion that carcinoma of the thoracic duct is not so rare as is generally believed. He himself met with twelve cases in the course of two years. In eleven of these the primary tumour was infradiaphragmatic and in the twelfth was mammary. In some of the cases the cross section of the duct was in part as thick as the little finger. Its lumen was sometimes obstructed, sometimes free, and frequently tumour cells were found in the midst of lymph [or blood coagula, in addition to forming part of the thickenings in the wall of the duct. The author believes that involvement of the duct arises from cells which become caught in coagula, and after organisation of these latter develop and invade the interior of the duct. Once the duct is attacked retrograde metastases can occur in the lungs and elsewhere. M.

Raw Meat Feeding in Tuberculosis.—Philip (*Lancet*, December 23rd, 1905), reports his experience in the treatment of tuberculosis by raw meat. The meat, he says, may be ordered in one of three ways—namely (1) as pounded raw meat; (2) as meat juice; (3) as raw meat soup prepared with milk. The clinical results that he claims are (1) Improvement in general

appearance and in muscular tones; (2) slowing of pulse with rise in blood tension; (3) rapid increase in hæmoglobin; (4) increase in weight; (5) lowering of a hitherto raised temperature; (6) general improvement in gastro-intestinal functions, and improvement in local lesions. These observations are the result of many years' experience, and they are confirmed by experimental investigations.

M.

Convulsions in Typhoid Fever.—Osler (*Practitioner*, Jan. 1906) discusses the occurrence of convulsions in typhoid fever. Murchison has pointed out the rarity of the phenomena, even in serious cases of the disease having met only with six cases out of a total of 2,960 typhoid patients. At the Johns Hopkins Hospital convulsions occurred in eight out of a total of between 1,500 and 1,600 cases. Osler groups these eight cases into three classes, according to the period of the disease at which the convulsions appeared. In the first class where the convulsions appeared at the onset of the disease there were two cases both of which ended favourably. In the second class the convulsion is a manifestation of the toxæmia and occurs during the course of the disease. Half of the cases belonged to this class and two of them eventually ended fatally. One of these patients admitted on the twenty-eighth day of the disease with an attack of great severity had on the next day five separate convulsive attacks after which, though there was no paralysis, there was marked rigidity and increased knee jerks. Eventually the rigidity almost completely disappeared and the patient was able to leave hospital but died at home about a week later. In the third class where the convulsion is the result of severe cerebral complications there were two cases both of which ended fatally. In one case the convulsions occurred at noon and the patient died some six hours later. *Post-mortem* examination showed thrombosis of the branches of the middle cerebral artery due to extensive arteritis. The other case was one of combined typhoid and tubercular infection, and at the *post-mortem* there were evidences of fresh tuberculous meningitis. Osler states that in the six cases of meningitis in his typhoid series only one had convulsions. In a few rare instances convulsions occur from unknown causes during convalescence. On the whole, considering the alarming nature of the complication the prognosis is not very grave.

K.

Xanthelasma and Chronic Jaundice.—Futcher (*Amer. Jour. Med. Sci.*, December, 1905) contributes a paper on this subject founded on the only three cases which occurred in the wards of the Johns Hopkins Hospital, during the first sixteen years of its existence, ending May, 1905, among 18,400 medical admissions, including a large number with chronic jaundice. The history of the three cases is briefly as follows:—1. Female, aged 30, gives a history of enteric fever about three and a half years before admission, during which she had cholecystitis. About thirteen months before admission she became jaundiced and the jaundice has persisted ever since. There had been severe pruritus. About eight months after the onset of the jaundice she noticed flat yellow patches appearing on the palms of the hands, elbows, axillæ, and sides of the neck. On admission there were numerous patches of various sizes, some of which were raised but the majority of which were flat. Later some small patches appeared over the upper and lower incisor teeth. The blood coagulation time was eight minutes and fifteen seconds, but after treatment with calcium chloride it became reduced to three minutes and fifty-five seconds. The patient was operated on and several gall-stones removed. Four years later the xanthomata had completely disappeared. Case II.—A female, aged 39 years, had persistent jaundice for eight years before admission, and two years ago had developed yellow patches on the palms of the hands and subsequently on other parts of the body. The liver was enlarged and the gall-bladder could be felt below the edge of the

ribs. In this case the blood coagulation time was fourteen minutes and under treatment was reduced to four minutes and fifty-three seconds. Patient refused operation and died a few days after leaving hospital. *Post-mortem* gall-stones and biliary hypertrophic cirrhosis of the liver were found. In this case there were numerous nodular xanthomata. Case III. Female, aged 42, had persistent jaundice for two and a half years before admission, during one and a half of which she had noticed yellowish patches developing below the eyes. Exploratory laparotomy was performed, but no gall-stones were found and a diagnosis of hypertrophic cirrhosis of the liver was made. In this case the xanthomata were confined to the eyelids. Dr. Williams made a careful histological examination of xanthomata excised from Cases I. and II., and came to the conclusion that they are of endothelial origin, thus differing from Crocker, who held that the primary factor was an inflammation and that the whole process was of toxæmic origin.

K.

Stokes-Adams Disease.—Stengel (*Amer. Jour. Med. Sci.*, Dec. 1905), reports a case which practically establishes the fact that experimental heart block and the phenomena of this disease are identical. He first reviews the experimental work which has been done to demonstrate the phenomena of heart block, and especially that of Erlanger. Erlanger, by a carefully devised experiment on the intact heart of dogs was able to compress the auriculoventricular bundle of His and thus produce heart block, and he had suggested that the phenomena of the Stokes-Adams disease might probably be due to the involvement of His' bundle by a patch of sclerotic endocarditis beginning on the anterior mitral leaflet at its base and aortic border and extending to the interventricular septum where the bundle of His passes upward toward the ventricle. Stengel's patient was a man aged fifty-seven years, who two and a half years ago, while at work suddenly fell backwards and became unconscious for a few moments. Three months later he had a similar attack and then others in more rapid succession. He gave up working about five months before admission to hospital when the attacks had become very frequent. On admission the pulse rate was 36 and there was a loud systolic murmur in the mitral area in which region a systolic thrill could also be felt. The attacks now became much more frequent and during one the pulse stopped for two minutes and ten seconds. During the last few days of life a condition of complete heart block appeared to be present, the auricular and ventricular pulsations being entirely independent. On *post-mortem* examination a general arteriosclerosis was found. The heart was hypertrophied but the muscle normal in appearance except where an endocardial lesion affected a small area at the upper part of the interventricular septum. The chief lesion of importance was one on the anterior mitral leaflet, toward its base and aortic edge. This patch was of atheromatous character, sclerotic and white and it extended to the endocardium exactly over the bundle of His where this band passes from the ventricle to the auricle.

K.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynæcological and Obstetrical Literature."
- (4) "The Recent Literature of Anatomy, Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

MR. HY. M.—Unfortunately for you the early admission you made to the patient gives him a suggestive hold of you; if he is determined to prosecute his claim we advise you to compromise the matter, as the law costs would be heavy, even were you to gain your case.

DR. S. E. T.—There are already so many duties the profession is called on to perform gratuitously, or for next to nothing, that we can hardly agree with your suggestion to make another ailment notifiable.

EDINBURGH STUDENT.—The work referred to is the most reliable, and at the same time the pleasantest to read on the subject with which we are acquainted.

DR. A. W.—Next week if possible.

L. L. ALEXANDER.—The volume of medical journalistic literature upon the subject is enormous, but the pith of it would not be hard to compress within a short paper, say, of 1,000 words. Although the discovery was first announced only within a year it has been the object of almost universal investigation. There is plenty of room, however, for independent work, if original and skilled.

WISE AND OTHERWISE.

At a recent meeting of physicians, an American contemporary informs us, one speaker remarked that "the rage for parcelling out the human frame into special territories is passing all bounds. We have specialists for the nose, the throat, the ear, the lungs, the heart, the genito-urinary organs, the rectum, the mouth, the brain, &c. It seems to me, gentlemen, that it will not be long ere the specialists, like Alexander, will have to sigh for new regions to overcome. So far as I can see, the umbilicus is about the only portion of the human body not allotted to a specialist."

Whereupon a veteran practitioner exclaimed: "Doctor, you're forgetting the naval surgeons."

KARL STROMMEYER.—It would be simpler to enter one of the London medical schools, unless you care for one of the provincial universities. In some of these an arts degree is compulsory, and means a longer period of residence.

C. F. (Earl's Court).—If you want to find out the present position of the hospital you mention you had better write to the Secretary of the Hospital Saturday Fund, which we understand is now engaged in making a special inquiry. It will be well carefully to disassociate past scandals from present conditions, which the committee claim to have set straight absolutely from one end to the other.

DR. R. J. L.—Your letter is unavoidably crowded out of our present issue.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, JANUARY 31st.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Mr. T. Adams: The Garden City and the Cheap Cottage.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5 p.m. Papers:—Dr. A. Morrison: The Present Position of the Treatment of Cardiac Disease by Baths and Exercise. (If time permits) Dr. Braithwaite (Buxton): Cases treated at the Devonshire Hospital by the Buxton Waters.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. F. L. Daniel: Clinical (Surgical). 5.15 p.m. Lecture:—Dr. P. Stewart: Disorders of Articulation.

THURSDAY, FEBRUARY 1st.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.15 p.m. Annual General Meeting. Election of Officers. 8.30 p.m. Paper:—Mr. W. Bateson: Mendelian Heredity and Its Application to Man.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Dr. A. J. Whiting and Dr. G. Basil Price: Clinical and Pathological Demonstration (illustrated by lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinicque. (Surgical.) 5.15 p.m. Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—8 p.m. Dr. M. Dockrell: Syphilis: I, History and Primary Invasion (Constitutional and Local). (Chesterfield Lecture).

FRIDAY, FEBRUARY 2nd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. A. Lawson: Clinicque. (Eye.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 p.m. Dr. G. N. Meachen: Acne and Its Treatment.

THURSDAY, FEBRUARY 8th.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Dr. Jellet: I, Advanced Carcinoma of both Ovaries; II, Double Pyosalpinx associated with the presence of a Four Months' Extra Uterine Fœtus. Dr. Bedford Fenwick: Two Cases of Fibroid Complicated by Pregnancy. Dr. H. Macnaughton Jones: A Note on Cryst. of the Vagina. Paper by Dr. Jellet: Notes on two rare conditions met with in the Pelvis during Operation. The President's Inaugural Address.

Vacancies.

Beckett Hospital, Barnsley.—House Surgeon. Salary £100 per annum and all found. Applications to R. Pawser, Hon. Sec., 8 Regent Street, Barnsley.

Bradford Poor Law Union.—Resident Assistant Medical Officer. Salary £100 per annum with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22 Manor Row, Bradford.

Burton-on-Trent Infirmary.—House Surgeon. Salary £120 per annum, together with furnished rooms, board, coal, and light, free. Applications to the Hon. Secretary, Mr. John Wood, the Infirmary, Burton-on-Trent.

Cheltenham General Hospital.—Surgeon-in-Charge of the Branch Dispensary. Salary £90 per annum, with board and lodging at the General Hospital. Applications to W. H. Head, Secretary.

Kent and Canterbury Hospital.—House Physician. Salary £90 a year, with board and lodging. Applications to the Secretary.

Kent and Canterbury Hospital.—House Surgeon. Salary £90 a year, with board and lodging. Applications to the Secretary.

Leeds General Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary to the Faculty at the Infirmary.

Royal Sea Bathing Hospital, Margate. Resident Surgeon. Salary £120 per annum, with board and residence. Applications to the Secretary, R.S.B.H. Offices, 13, Charing Cross, London.

Sierra Leone.—Princess Christian Hospital, Freetown, West Africa.—Medical Officer. Salary £250 a year and rooms. Applications to Rev. Arthur Sinker, 136 Southwark Park Road, S.E.

St Mary's Hospital Medical School, Paddington, W.—Lecturer on Physica. Salary £100 per annum. Applications to H. A. Caley, M.D., F.R.C.P., Dean.

Appointments.

BALL, J. BRAMLEY, L.D.S.R.C.S.Eng., Dental Surgeon to the Royal Hospital School, Greenwich, S.E.

COX, FRANKLIN, M.R.C.S., L.R.C.P.Lond., District Medical Officer for the Clutton Union.

DOBSON, MARGARET B., M.D.Lond., Pathologist to the West Riding Asylum, Wakefield.

FITZWILLIAMS, DUNCAN C. L., M.D., Ch.B., F.R.C.S.Edin, Casualty Officer to the Hospital for Sick Children, Great Ormond Street.

GARRATT, G. C., M.D.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Singleton District of the county of Sussex.

HARRIS, HERBERT, M.D.Edin., Honorary Medical Officer to the Rochdale Infirmary.

LAVAL, EVARISTE, M.B.Edin. Assistant Medical Officer to the Warneford Mental Asylum, Oxford.

LYSTER, ROBERT ARTHUR, M.B., Ch.B.Lond., D.P.H., B.Sc. in Public Health, Assistant County Medical Officer of Health to the West Riding County Council.

MILLER, JAMES WEBSTER, M.B., Ch.B.Aberd., Assistant Medical Officer at the Dorset County Asylum.

MONTGOMERIE, HUGH MAYER, M.D., O.M.Edin., Physician to the West Cornwall Infirmary, Penzance.

MONTGOMERY, JAMES BARCLAY, M.D.Glasg., F.R.C.P.Lond., M.R.C.S., Honorary Physician to the West Cornwall Infirmary, Penzance.

POLLOCK, W. B. INGLIS, M.D.Glasg., Pathologist and Bacteriologist to the Glasgow Eye Infirmary.

SUTCLIFFE, AMELIA, M.B., Ch.B.Edin., Clinical Assistant to the Southern Branch of the Leeds Public Dispensary.

Births.

FITZGERALD.—On Jan. 24th, at Chatham Down, near Canterbury, the wife of G. C. FitzGerald, Esq., M.D., of a daughter.

GAITSKELL.—On Jan. 23rd, at Burgess Hill, Sussex, the wife of H. Ashley Gaitskell, Esq., M.D., of a son.

HARVEY.—On Jan. 24th, at Clarence Villa, Hartfield Road, Wimbledon, the wife of Joseph Harvey, M.B., of a daughter.

Marriages.

FINCH-SMITH.—On Dec. 13th, at Boree Cabonne, Sidney, youngest son of the late Dr. Robert Finch, of Blackheath, London, to Mary Maud, second daughter of Lancelot Noel Smith, of Boree Cabonne, New South Wales.

LINTON-ROBBS.—On Jan. 27th, at St. Stephen's Church, Dalwick Denys Linton, eldest son of the late Right Revd. Sydney Linton D.D., Bishop of Riverina, N.S.W., to Annie Louise (Nancy) youngest daughter of the late Charles Henry Denny Robbs, M.B., of Grantham.

Deaths.

CAHILL.—On Jan. 24th, at 9 Edith Villas, West Kensington, London Elizabeth (Beasle), second daughter of the late Thomas Cahill, M.D.

HAWKES.—On Jan. 22nd, at 4 West Cliff Road, Ramsgate, suddenly, of aneurism, Edward John Hawkes, L.R.C.S., L.R.C.P.Edin., in his 63rd year.

LEDGARD.—On Jan. 23rd, at Kirkby Lonsdale, William Edward Ledgard, L.R.C.P.Edin., M.R.C.S.Eng., elder son of the late J. A. Ledgard, Surgeon, Wetherby, aged 59 years.

WAUGH.—On Jan. 25th, at Conger House, Teddington, Bedfordshire, Lily Lavinia, wife of J. Waugh, M.D., J.P., aged 45 years.

NOTES AND COMMENTS.

The Doctor's Boy.

TIME was when "the doctor's boy" was a familiar figure in social life. Clad in a neat page's uniform, and resplendent with many buttons, he went his rounds, leaving at the houses of his master's patients physic which he unearthed from the depths of a double-flapped wicker basket. Even now, in the year 1906, it appears he has not finally retired from the scene. At a London police court last week a medical man was fined for keeping a male servant without a licence. In vain he pleaded that a doctor's boy who carried medicine and ran errands was no less necessary than the untaxed oilman's boy who delivered bundles of wood. Notwithstanding this defence, which, by the way, presents in tabloid form the commercial side of the practitioner's life the magistrate upheld the view of the opposite side, namely, that a boy who cleaned boots and windows, polished the big handle of the front door and so on, was a page in the eye of the law. This decision means, therefore, that medical men may be in future called upon to pay duty upon a boy employed by them mainly in a domestic capacity, and incidentally only in the delivery of medicines.

A Liverpool Skin Specialist—so-called.

SOME day the public will wake up to the farce that is being played at their expense by the legislature in the matter of the Medical Acts. The depths of infamy have surely been sounded by a Liverpool quack, whose proceedings were recently brought under the notice of a coroner's jury. It appears that the deceased woman was suffering from a "highly septic" inflammatory skin affection, for which she was attended by a medical man. Upon her improvement, however, he was told his services were no longer needed, and that a "skin specialist" was going to look after her. The person thus imported was an unqualified man, named Wolfender. His remedies seemed to have consisted of lard, olive oil, beeswax, and so on, but lacking the necessary antiseptics. Under these circumstances the septic condition returned in full force, and the unfortunate woman died. The Coroner censured Wolfender, and told him that he had brought himself "very near" a criminal prosecution. It is not easy to see how such notorious quackery could escape criminal prosecution, even with the machinery of our feeble and antiquated Medical Acts. The attention of the Liverpool police and of the Public Prosecutor may well be called to this case. The crucial point is whether

the death would have occurred under proper—i.e., duly qualified and recognised—medical treatment. A negative answer spells manslaughter.

Medicine as a Great Electoral Power.

THE analytical faculty of the Conservative party has been sorely taxed in the effort to lay bare the ultimate causes of their recent defeat at the polls. A hundred reasons, plausible and otherwise, have been advanced, laying the blame upon this, that or the other person or circumstance. It was left for a daring writer in the *Morning Post*, however, to draw up a formal indictment of the medical profession. One cause of his own defeat, he asserts, was the refusal to answer hundreds of questions "cunningly arranged to commit the answerer." "Though I saw a deputation on the subject of the British Medical Association," he writes, "and we agreed on all important points, one doctor refused to vote for me, though he sympathised in general party politics, because I still refused to sign a promise to vote as the string of questions demanded." According to this authority, then, the medical profession had a considerable finger in the recent election pie, whereas the professional journals have been singing jeremiads a generation over our wasted political opportunities. The two other reasons given by this defeated candidate were Chinese labour and the Post Office Vote. Medicine ran third.

The Union of the London Medical Societies.

THE Committee of Representatives responsible for the Society amalgamation propose to admit two grades of members. "Fellows" are to be admitted at a subscription of three guineas annually, and "Members" of a particular section at one guinea. We cannot say that we altogether approve of such an arrangement. The, to us, fundamental principle of an "Academy," or whatever the new Society is to be termed, is that every one joining it joins the entire organisation, and not one or other section. If two scales of fees are necessary by all means adopt them, but let each scale ensure full membership so far as the right to attend all sections is concerned. The one scale can carry with it the "Fellowship," the other "Membership," and distinctions can be made as to the use of libraries and reading-rooms, and to the receipt of the Society's Transactions. The scale of fees also appears to us to be wrong. Two guineas should carry with it the Fellowship and all rights, and by so fixing it the funds would not suffer since many men who under the present arrangement can join one Section for a guinea would gladly become Fellows if the privilege simply cost an extra guinea. Further, the Society cannot expect a great influx of country Fellows at three guineas, since that is too high a scale for

privileges that perhaps would be exercised only once or twice in the year. The Committee of Representatives would be well advised to add to their present proposals one for the admission to the Fellowship of men residing, say, one hundred miles from London at an annual subscription of one guinea.

LEADING ARTICLE.

THE STATE AND INEBRIETY.

It is claimed in all the Liberal newspapers and magazines that an era of social reform, the like of which has never been known, is about to dawn on the country. We hope with all sincerity that this is so. Both political parties in the past, partly through limitation of opportunity, partly—and principally—through lack of a sufficiently strong force of public opinion behind them, have touched social reforms only with tongs. But little party capital, it was felt, was to be made out of "parish pump politics," and most people had widely different ideas both as to what to do and how to do it. Every country gets the Government it deserves, and, if the great and pressing social reforms that are needed have been held in abeyance too long, the delay must be put at the door of the payer who called the tune rather than of the piper who did not play. But if the new Government is really agog with eagerness to be up and doing in the cause of the welfare of the people, we can point to a dozen hygienic and social problems that they may take in hand with the full and complete approval of the profession. At the moment there is one to which we would especially like to call attention. We mean the reform of inebriate legislation. The Acts relating to the restraints that should be placed on chronic drunkards are lamentably defective both as to scope and powers, and though there is little or nothing to repeal there is a vast deal to be done in the way of extension and consolidation. The modest little Act which the late Lord Ritchie guided so skilfully through Parliament is simply an instalment of a wider and more far-reaching measure designed to abolish, or at any rate materially to lessen, the scandal of inveterate drunkenness with all its tales of misery and degradation. It is thoroughly recognised by the medical profession that the chronic drinker is far more than a ne'er-do-weel; he is as great an enemy to himself as to his fellows, and he is incapable, after a certain stage, of reforming his habits. In fact, his complaint is one of the mind, and should be dealt with as such. In speaking of the drunkard as "he" we do not lose sight of the fact that in the even sadder and more hopeless cases the victim is a woman. If a vote were taken among practitioners as to which class of patient they found themselves most powerless to help, we fancy it would be pretty generally given for the female inebriate. Degrading and demoralising as is a drunken husband, it is impossible to compute a tithe of the evil wrought by a drunken wife and mother, and, as the law stands, while either the one or the other fails

to make frequent public exhibitions of their vice in the streets, no relative or official can do more than use moral suasion to induce them to put themselves under medical treatment or restraint. If legislators would clearly understand that the disease is of the mind, they would not hesitate to consent to treat such patients as the other classes of mentally diseased persons are treated at the present day, namely, by compulsory detention in properly organised establishments under public control and Government inspection. As it is, they fear to trench on the sacred principle of individual liberty. It is, then, much to be desired that a Royal Commission should be appointed at an early date to gather evidence and recommend legislation. The feeling in Scotland on the subject is already running high, and the municipalities of the leading towns have now before them the draft of a Bill which it is proposed to promote in Parliament with a view to giving extended public control over inebriates. In this Bill, among other things, it is provided that a near relative of the drunkard may, with the consent of two magistrates, call upon a Sheriff to institute a public trial before a jury of the party complained of, and if the jury find the accused to be an habitual drunkard, and by reason of his habits and conduct a fit and proper person for treatment in an inebriate reformatory, the Sheriff may sentence him to a term of detention not exceeding three years in duration. It is surely obvious that a Bill making such a decided inroad into personal freedom has not the slightest chance of passing into law except as a Government measure, and the procedure recommended is open to the gravest criticism. The publicity of the process as proposed would act as such a deterrent with relatives, especially of the well-to-do classes, as would make the Act a dead letter. Moreover, there would be opened up channels for persecution and blackmail which should not be possible. A Royal Commission could take all circumstances and factors into account and produce a report on which official action would be based, and based authoritatively. Such a Commission would probably find the method least open to objection would be one fashioned on the analogy of the lunacy proceedings, namely, either by medical certificate and magistrates' order, or by inquisition as in the case of Chancery lunatics. The latter, if the expense could be rigidly cut down, would present many advantages, especially in the case of drunkards with important responsibilities or property. Legislation on temperance questions is generally strongly opposed by "the trade," but the licensed victuallers recognise the inebriate as their own enemy as well as that of society, and more than one leading member of the trade has spoken approvingly of the principle of the Scotch Bill already mentioned. We believe that the House of Commons would present no difficulties to the passage of a well-thought-out and authoritative scheme, and such a measure would be one by which the Government of the day would gain credit and gratitude on every hand.

NOTES ON CURRENT TOPICS.

The Election of Direct Representative for Ireland on the General Medical Council.

THE result of the election of the Direct Representative for Ireland will probably come as a surprise to many members of the Profession, although perhaps those who knew most were inclined to think that the voting would be very close. That their opinion was correct, the result has shown, for never in the history of these elections has the majority of the successful candidate been so small. To the victor go the spoils, and therefore we desire first to offer our sympathy to the defeated candidate. Sir William Thomson during his period of office has discharged his duty in a thoroughly capable manner, and with the knowledge that he has done so, and that his defeat is due to the not unnatural desire for a provincial representative, will, we trust, remove from his own mind any sense of the bitterness of defeat, just as it tells his medical brethren that his defeat was due to no other cause than the revolution of the hands of the clock of time. The tendency of the time showed that sooner or later a provincial candidate was bound to come forward who would receive the confidence of the majority of his medical brethren. To the victor we offer our congratulations. Dr. Leonard Kidd has had a hard and uphill fight, and has fought it in an honourable and straightforward manner. Should he in future be as *suaviter et sagaciter in modo* as he has proved himself *fortiter in re*, his success as a direct representative of the medical profession is assured. On one point we desire to congratulate the entire profession in Ireland. Despite many efforts by lay organs and individuals, no trace of sectarian or political venom has been allowed to mingle with the desire that the most suitable man should be found to represent the profession. We are confident that Dr. Leonard Kidd will not in his official capacity be influenced a hair's breadth by such prejudices, and we also believe that should a medical man of different creed or political faith come forward on a subsequent occasion, who is as suitable a candidate as were those at the present election, he will receive the same whole-hearted support from all sections of the medical profession, provided that his appeal to them is based on his professional attainments and reputation and on those alone.

Instruction in Temperance.

THERE is no doubt that some good may be done in the direction of temperance reform by proper instruction given to the young. It is, however, a matter of considerable difficulty to choose the best form in which to administer such instruction. On the one hand, a child pays but little attention to mere statement of facts unless it can be made interesting, and on the other if any extravagance be used he is likely, on reaching what has been wittily called "years of indiscretion," to discard too much of his early training. While

medical men are, perhaps, not the best fitted to give sensational lectures on such subjects as temperance, they are above all others fitted to give sound and sane advice on the physical aspects of the question. The plan has, therefore, been adopted in some places of inviting medical men to give short lectures on temperance in primary schools, and we believe that teachers generally have regarded the results as successful. Some two years ago, a number of lectures of this sort were delivered in Dublin schools with great success, and we understand that this spring it has been arranged that lectures on temperance shall be delivered by medical men in practically all the parish schools of Dublin and the suburbs. The organizer of the scheme, the Rev. Principal Moore, has had no difficulty in obtaining the co-operation of many well-known physicians, most of them members of hospital staffs, and we have no doubt their efforts will have a good effect.

Sleep at Schools.

WHEN Canon Lyttelton was appointed headmaster of Eton various stories were set about of his peculiar notions about boys' dress and habits and of the changes he intended to introduce into Eton, the home of authority and tradition in all that pertains to high-class education. The fact was that Canon Lyttelton, among prominent classical schoolmasters, was the one who perhaps best realised what modern hygiene had to teach with regard to the development of the young, and we welcomed his appointment particularly on the ground that if he could introduce his ideas into Eton their influence might spread through the public school system. So far we have not heard of any startling revelations, but one change has just been made which will probably be resented as a curtailment of Eton privileges but which may also be regarded as a bold and wise step. Impressed by the force of the contentions lately raised as to the length of sleep given to boys at public schools, Canon Lyttelton has fixed the bed-time of the lower school at half-past nine instead of ten, and of the upper school at ten instead of half-past, so that all boys will get an extra half-hour in bed. Whatever the lads themselves think, their parents should be very grateful to a headmaster who puts himself on the side of common sense and sound hygiene.

Work for Consumptives.

ONE of the many difficult problems in connection with tuberculosis is the provision of suitable work for consumptive patients. Too often it happens that a patient, improved and educated by sanatorium treatment, has to return to surroundings the worst possible of the kind for his condition of health. It is obvious that country life, or, at any rate, open air work is the best suited to improve his health, but we can hardly hope to find country or open air employment for the thousands of town tradesmen, to speak of no other class, who suffer from tubercle.

A city-bred subject, whether in good or bad health, is not likely to content himself with country life, even were it possible to find work of which he would be capable. An additional difficulty is that employers nowadays have a very marked dread of receiving into their houses, offices, or places of business a person infected with tubercle. The public has, indeed, become firmly convinced of the infectivity of tubercle, and it rushes to the extreme of regarding every unfortunate consumptive as plague-stricken. It is the duty of medical men to make clear that a consumptive patient, instructed in hygienic measures and careful to carry them out, is in no way a danger to the community. In papers on the whole subject in the January number of *Tuberculosis*, by Drs. Jane Walker and W. J. Fanning, the suggestion is made that in every large town there should be a central bureau charged with the duty of finding employment for consumptives, particularly those recently discharged from sanatoria. An organisation of this sort would attract to it offers from well-disposed private individuals, and would doubtless be a great boon to a very unfortunate class.

'A Ladies' Health Society.

THE ladies of Manchester have set, in the formation and working of their Ladies' Health Society, an example which might well be followed in other towns. The Society is entirely voluntary, and it maintains, aided by the Corporations of Manchester and Salford, a large number of health visitors who, under the direction of the medical officers of health of the two cities, spend their time in visiting the dwellings in their districts. They endeavour, by persuasion and advice, to bring home to the women of the working classes the value of cleanliness, fresh air, and wholesome food. Particular attention is given to young mothers and their babies, and, when artificial feeding is absolutely necessary, advice is given as to the most suitable forms of food. Though the intention of the Society is not eleemosynary, yet in some cases it has been found advisable to give aid in money or in kind. For instance, it has sometimes happened that a mother, herself on very inadequate diet, is found nursing a child. Instead of giving artificial food to the child the visitor has provided the mother with some addition to her own diet, such as a given quantity of milk, the result to mother and child being excellent. In cases of deficient sanitation or other grave fault, the visitor, in case suasion fails, has power to invoke the aid of the public health department.

Lincoln Epidemic Compensation.

WE commented in these columns some time ago on the fact that a large number of actions for damages were being prepared against the Lincoln City Council in relation to the late typhoid epidemic. That epidemic, our readers will

remember, was due to the systematic neglect of medical warning and advice which had been given year after year. The outbreak was extensive and the provision of hospitals, medical relief, and a pure water service involved the town in large expenditure. On top of all this came the threat of actions for damages to be brought by the actual sufferers. Had these actions been persisted in, and proved successful, the rates of the city would have risen to such a crushing figure that the prosperity of the town would have been gravely compromised. At the same time, it would have been well from a public standpoint had it been possible to demonstrate conclusively that a negligent sanitary authority was liable for the results of their negligence, as it would have brought home a sense of civic responsibility to those councillors who regard their seats on municipal bodies as positions of privilege, or as opportunities for advancement, rather than as trusts committed to their keeping by their fellow citizens. We learn, however, that the Lincoln Council have decided not to face the music, and have decided to award compensation on a scale which involves them in a nett cost of £4,000. This may be well for the ratepayers, and may be considered by them a lucky let-off, but a fight to the finish would have had a larger public value. The citizens themselves could not have been altogether cleared of responsibility for contributory negligence in that they continued to elect representatives who were determined not to alter the old water-supply arrangements, and the terrible results of this wilful stupidity could not have been made known too widely among the inhabitants of other towns.

Medical Men in the New Parliament.

IT is interesting to note the occupations represented in the newly-elected House of Commons. Heading the list we find 105 barristers, as against the next numerous class, that of journalists, who number 36. If to the barristers we add 34 solicitors, we have the proportionate figure of 139 representatives of the legal profession. Hitherto the great influence of the legal element in the Commons has not made itself felt either in the clearness of legislative Acts or in the urgently needed codification and simplifying of law. Possibly under the influence of the new democracy, the lawyers will exercise their powers more freely in the interests of the nation. There are 54 Labour M.P.'s, who should have something to say on the question of law reform. There are four brewers and four distillers, a much smaller number than that usually present in the House, and one that may possibly augur well for temperance legislation in the near future. Of medical men there are ten, a number totally out of proportion to the enormous influence wielded by their profession upon the social, the moral, and the scientific enlightenment and advance of the community. It is difficult to see how our professional representation can be increased, seeing that most of its members lead busy lives and are not, as a rule, possessed of

independent incomes. The scheme whereby the British Medical Association hopes to return professional representatives to Parliament appears to be futile, if only on the ground of the impossibility of reconciling party differences. A Conservative practitioner, for instance, could hardly be expected to vote for an advanced Liberal, or *vice versa*, simply in order to increase the weight of the medical profession in the legislature. That sacrifice of individual principles, however, is asked for by the Association.

A British Dumping Ground for American Quacks.

FOR years past the United Kingdom has been exploited by American quacks. By availing themselves of the simple commercial method known as "dumping" they compete boldly with our own extensive knot of producers, vendors, and proprietors of sham remedies. The American quack simply places on foreign markets the overplus of the particular fraud he is engaged in manufacturing. Unfortunately, on this side of the Atlantic we Britishers have no effective law against the sale of secret or quack nostrums, no matter how flagrant their pretences or how heartless their fraudulent practices. Judging from the signs of the times, the evil of this unwholesome alien competition is likely to increase rather than to lessen in the near future, for in America the more enlightened portion of the community appears to be getting somewhat out of patience with the methods of quackery. Not long ago, President Roosevelt directed the prosecution of some quack proprietors for obtaining money under false pretences. Now we hear of a medical society prosecuting a man named Hilgut for practising as a doctor without a licence. His plan was simple. He sold to credulous customers "magic boots," which he guaranteed to cure paralysis, locomotor ataxy, neurasthenia, heart disease, sciatica, tic douloureux, St. Vitus dance, and many other maladies. It is said that Mr. C. W. Schwab paid £1,000 for a pair of these precious appliances, and Bishop Potter £300. The "magic" is held to be a pinch of white pepper in the soles of the boots. Fantastic and foolish as this story may seem, it is not a whit less ridiculous than the claims of the "rheumatic ring," which has an enormous sale in the United Kingdom for the cure of rheumatism. American law, however, can punish quacks effectively, whereas British law cannot.

Sanitation in the Isle of Wight.

ONE is accustomed to look on certain South Coast spots specially favoured by nature as ideal resorts for regaining health and passing happy holidays. From time to time the ruthless inspectors of the Local Government Board shatter these ideals by publishing reports in which the sanitary circumstances and administration of these enticing resorts are shown to be far from conducive to either health or enjoyment. Several instances will occur to each reader in which this iconoclastic process has been brought to bear. As a result of complaints,

the Local Government Board, which has repeatedly drawn the attention of the Rural Council of the Isle of Wight to the want of proper sanitary inspection, sent Dr. Timbrell Bulstrode to report in detail. The island was thoroughly explored by this gentleman from a sanitary point of view, and after full inquiry and investigation he has furnished the Board with a report, saying that in his opinion the present system is bad and that no improvement can be looked for till the machinery is completely overhauled. One of the complaints he makes is that the duties of Inspectors of Nuisances and of Highway Surveyors are discharged by the same person in many instances, with the result that both functions are not performed as they should be. He urges that disinfecting apparatus, proper arrangements with regard to infectious diseases, and other reforms should be instituted, and that the Board should not sanction financial aid to the Rural Council till modern requirements are satisfied. It remains with the Isle of Wight to clear its character as a health resort by seeing that these changes are made at an early date.

PERSONAL.

ON February 1st, news was cabled from the Cape that Dr. Anson Donaldson, of Brockville, Canada, had been shot down by German soldiers at Swakopmund. As a matter of fact, Dr. Donaldson sailed from Liverpool last week as Surgeon on the Elder-Dempster steamer *Papele* for West Africa.

MR. A. T. COOKE has tendered his resignation of the post of Surgeon to the Stroud General Hospital after more than forty years' service. He was the first house surgeon to the Institution.

A HANDSOME presentation has been recently made to the Hon. William Thomas Prout, C.M.B., M.B. Edin., Principal Medical Officer in Sierra Leone, by fellow officials on the occasion of his recent decoration with the companionship of the order of St. Michael and St. George.

THE first of an important series of lectures upon food and nutrition was delivered by Dr. William Stirling, Fullerian Professor of Physiology, at the Royal Institution, London, on the 5th instant.

THE sum of £100 has been left to the Medical Society of London, by the will of the late Mrs. Gant, the widow of a former president.

THE Basingstoke Cottage Hospital receives £1,000 under the will of the late Sir Wyndham Spencer Portal.

VACANCIES on the Council of the Royal College of Physicians of London have been filled up by the appointment of Dr. William Osler, Dr. H. R. Crocker, Dr. H. H. Tooth, and Dr. T. D. Acland.

THE late Mr. Capper Pass, of Bristol, bequeathed £1,000 to the Bristol General Hospital, and £2,000 more conditional upon his son attaining his majority.

UNDER the presidency of Mr. L. A. Bidwell, the annual dinner of the West London Medico-Chirurgical Society takes place at the Grand Central Hotel, on the 7th instant (date of present issue).

PROFESSOR EBSTEIN, of Göttingen, who is seventy years of age, is resigning the directorship of the University Clinic and Polyclinic.

MR. A. H. TUBBY will deliver the Hunterian Oration at Pagani's Restaurant, London, W., on February 14th, at 6.30 p.m., on "The Treatment of Certain Forms of Paralysis."

MR. J. C. HUDSON will read a paper on "American Schools and their Relation to the Child and Society," before the British Child Study Association, at the Parkes Museum, London, on the 8th instant, at 8 p.m.

PROFESSOR W. KEERTE, of Berlin, will preside at the Thirty-fifth German Surgical Congress to be held at Berlin, April 4th to 7th.

A CLINICAL LECTURE

ON

SYPHILITIC PSEUDO-GENERAL PARALYSIS.

Delivered at the Adelaide Hospital, Dublin.

By HENRY T. BEWLEY, M.D. Dub., F.R.C.P.I.,

Physician to the Hospital; Lecturer on Forensic Medicine and Hygiene, Trinity College, Dublin.

SYPHILIS affects the central nervous system in a variety of ways. The connection between the syphilitic poison and the nervous lesion may be direct, as when gummata form, or when syphilitic end-arteritis occurs; or the connection may be indirect, as when the syphilitic poison lowers the vitality of the nervous structures so that they become liable to certain forms of degeneration, such as occur in tabes, and in general paralysis. You must, however, always remember that in some cases of tabes and of general paralysis no antecedent syphilis is demonstrable; so that we are not in a position to say in all cases of these diseases that even an indirect connection with syphilis exists.

The cases which I wish to bring under your notice belong to the first group; the lesions are part of the tertiary stage of syphilis; and they are directly amenable to specific treatment—a feature which markedly distinguishes them from the diseases belonging to the second group—the so-called parasymphilitic diseases.

But if the effects of treatment sometimes help us to distinguish between diseases belonging to one or other of these groups, yet there is not the same degree of difference between their symptoms; we may be for a while in doubt as to the category a certain case belongs.

The direct effects of syphilis on the central nervous system may be divided into four groups: (1) symptoms (hemiplegia, aphasia); (2) focal lesions (gummata) arising from vascular occlusion due to end-arteritis of the cortex and cortical membranes; (3) gummatous meningitis of the base of the brain; (4) diffuse and wide-spread arterial and meningeal lesions. The cases which I am showing you belong to this last group. They present both mental and motor symptoms, and they belong to a group of cases which often present symptoms which closely simulate those of general paralysis of the insane. But there is a very real difference between general paralysis and the disease which I am about to describe, to which the names of pseudo-general paralysis or syphilitic dementia have been given.

The history of the first case is as follows: Some years ago this young man, who now is *æt.* 30, contracted syphilis. He was treated and appeared perfectly well till June, 1904, when he one day fell unaccountably while playing at a school fête; he said he felt as if his foot suddenly refused to obey his will. In July, 1904, he awoke one morning seeing double, and this trouble continued for four days. In October, 1904, he became sleepless and began to suffer from neuralgic pains in his head.

In January, 1905, he consulted Dr. James Little, complaining of general weakness and want of energy. On February 14th, he awoke feeling as if his face, arm, and leg on the left side were asleep; when he got up he found he could not walk properly, on account of weakness of the left leg; and soon afterwards he fell while walking across his room. The weakness increased, and extended to his right arm and leg. His speech became affected, and his utterance slow and hesitating. He became unable to stand, and was admitted into hospital on March 13th, 1905, under the care of Dr. Little, and subsequently I took charge of the case.

When admitted to hospital he was unable to stand alone; his legs were both weak and the deep reflexes greatly exaggerated. His mind had become enfeebled, and his memory exceedingly defective, so that if he tried to read he was unable to grasp the meaning of the

passage. His articulation was indistinct and confused. When asked a question he would pause a considerable time before answering and then the words were slurred and indistinct, and he had much difficulty in forming even simple sentences. He occasionally complained of headache. There was a certain expressionless appearance in his face. His tongue protruded to the right. His pupils and retinae were normal, but there was a defect in the conjugate lateral movements of the eyeballs. His grasp was very feeble with both hands. His urine was passed involuntarily every three or four hours, and he had very defective control over his rectum. His thoracic and abdominal organs were normal, except that his heart's action was feeble.

Here, then, we had a case of disease of the central nervous system so wide-spread in extent that almost all parts were affected from the intellectual centres in the brain down to the centres which preside over the bladder and rectum, which are situated in the lumbar enlargement of the cord. When I first saw the case I was inclined to think the disease might be general paralysis, but the progress of the case showed that Dr. Little's diagnosis of diffuse syphilitic vascular disease of the central nervous system was correct. The patient was subjected to a course of mercurial inunctions, and subsequently was treated with iodide of potassium in doses increasing from 15 grains three times a day to 45 grains three times a day.

He, under this treatment, steadily improved. By July his mental powers had greatly improved, so that he was able to read a book and to remember quite well what he read. His speech was slow; there was slight slurring, and he spoke with great deliberation. His power of grasping was approximately normal. He could walk with the aid of two sticks; ankle-clonus and exaggerated knee jerks were present. Still he had trouble with his urine; every three or four hours the bladder would suddenly empty itself with a force which he could not restrain. The control of his rectum was also defective. In this state he left hospital and has since lived either in a suburb of Dublin or in the country.

As you now see him (December, 1905) he is vastly improved. His memory is quite good. His speech is fairly rapid but from time to time there is some hesitation. He talks in little rushes of words—a few words uttered quickly; then a pause; then some more words, something after the manner of a drunken man. His facial and ocular muscles are normal; his tongue protrudes a little to the right. His arms are normal; his legs are in a state of spastic paralysis; he can walk pretty well but tends to drag his toes, and his reflexes are much increased. He has not regained full control over his rectum, and the bladder still empties itself automatically every three or four hours, so that he must constantly wear a rubber urinal.

The second case is that of a gentleman, aged now about 50 years, who, about 2½ years ago contracted syphilis in a very severe form; about nine months later he had some kind of hemiplegic seizure from which he recovered to a very great extent. During the summer of 1904 he began to use wrong words—*e.g.*, when he wished for a drink of water he said "I want a book." This symptom continued at intervals from that time on. During the summer of 1905 his mental faculties were noticed suddenly to become duller than formerly. This dullness increased until in September he was quite stupid; he could not in the least understand a book when it was read aloud to him. In

October his speech became very imperfect ; he could only enunciate the simplest sentences, and that with difficulty and hesitation ; he forgot many words and also frequently called things by wrong names ; he became entirely unable to write ; when asked to write a very simple sentence he would slowly trace the first two or three letters correctly and then make a mistake in a letter, and finally write down an utterly wrong series of letters ; he had enough mental ability to know that he made mistakes but not enough to be much troubled about them. There was no obvious paralysis, but his muscles generally were weak.

I was asked to see him as the doctor who was treating him had a suspicion that the case was one of general paralysis. I came to the conclusion that the case was one of syphilitic dementia ; and as treatment could not be efficiently carried out at home, he was brought into a pay-ward in the hospital.

GENERAL PARALYSIS.	SYPHILITIC DEMENTIA.
Indirect, or may appear to be non-existent. Often later—after many years	Direct. Often occurs earlier—a few years after infection.
Delusions of expansive nature common. Dementia becoming more marked as the case progresses.	Enfeeblement (dementia).
A marked symptom.	Absent, or slightly marked.
Rare. When they occur, they may be temporary.	Common—(e.g., hemiplegia, monoplegia, aphasia).
Progressive tendency toward death.	Ill-defined ; may improve up to a certain point.
Antisyphilitic treatment unavailing.	Hg and KI often produce great improvement.
	Connection with Syphilis. Time of onset. Nature of mental symptoms. Tremor. Paralyses. Duration and course. Effects of treatment.

When admitted his chief symptoms were mental ; his brain formed ideas with slowness and difficulty ; he could understand only the simplest questions ; he could hardly speak as he had forgotten most words. He did not complain of headache ; there were no sensory symptoms ; his limbs were weak but there was no actual paralysis and no tremor, except for some old iritis his eyes were normal ; he had control over his sphincters ; his reflexes were all normal.

He was treated by mercurial inunction for a month, and is now taking iodide of potassium, 30 grains thrice daily.

As you now see him (December, 1905), his speech is quicker and more correct, but he still slurs some of his words. He has a much greater command of words than formerly, and his mental powers are greater than they were. He cannot, however, carry on any conversation and cannot understand a book when it is read to him. He is able to sign his name correctly,

though with difficulty. He will soon leave hospital and I shall advise that he should continue the iodide for some months. He has improved under the vigorous treatment, but I do not expect he will ever regain much mental energy.

In both of these cases there have been widespread lesions of the brain and spinal cord ; both cases were for a time supposed to be examples of general paralysis ; and yet not only were the symptoms somewhat different from those commonly found in this disease, but the course of the cases was entirely unlike what occurs in general paralysis. Both patients are suffering from syphilitic pseudo-general paralysis or syphilitic dementia ; they are the subjects of diffuse arterial and (probably) meningeal lesions of syphilitic nature.

I have embodied in tabular form (taken mainly from Fournier's work) the main features which distinguish this condition from ordinary general paralysis.

Optic neuritis, severe headaches and vomiting are more likely to occur in cerebral syphilis than in general paralysis. I need not dilate on these diagnostic points, for the cases you have seen illustrate most of them.

As regards prognosis and treatment, these cases are directly syphilitic ; they are a part of the tertiary stage of syphilis ; hence they are far more successfully treated than are such parasymphilitic diseases as general paralysis and tabes. In syphilitic dementia energetic treatment will probably check the course of the disease, and may cause great improvement. I am, however, doubtful if complete recovery ever occurs, especially if there is vascular disease. With regard to the mode of administering antisyphilitic remedies in these cases, I am in favour of a course of mercurial inunction followed by a prolonged course of iodide of potassium, the dose of the iodide being increased from 30 grains up to 120 grains a day, divided into three doses. I have never seen large doses disagree where small doses were well borne, and I am satisfied that large doses of iodide often succeed where small doses fail to relieve the symptoms.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by William Murrell, M.D., F.R.C.P., Physician and Lecturer on Medicine at Westminster Hospital, &c., on "Gonorrhæal Rheumatism and Gonococcic Infection."

ORIGINAL PAPERS.

A NEW METHOD OF SERUM THERAPY.

By D. M. PATON, L.R.C.P., L.R.C.S.Ed., L.F.P.S Glasgow.

(Concluded from page 121.)

V.—Inflammation, Suppuration, Abscess.—Serum treatment falls into line with present day pathology in that it ignores the distinction which used to prevail between what was then called simple and septic inflammation.

The various phenomena of inflammation need not be enumerated here, but for the purposes of treatment the whole course of inflammation may be divided into three stages.

1. The initial stage, including all that precedes the death of tissue.
2. The death of tissue and formation of pus.
3. The rupture or incision of abscess and elimination of the products of the previous processes.

1. In the stage which precedes the death of tissue ADS. when used properly is specific. The acute pain is the first symptom to be affected, and the patient can

soon be rid of that pain which will not give him rest. The following is a fair example:—

Miss M'C—, æt. 42, had been suffering from an acute bursitis of the left knee and had been continuously fomenting and poulticing it for thirty hours during which she had no rest, and when the prospect of another such night was before her she sought advice. She was at once given ADS., one dose every hour for the first three doses. At the time I said to her that she would probably be asleep before she had the third dose. The forecast was correct, as she fell asleep after the second dose and had to be wakened for the third. She took eight doses, and felt so well that she stopped the treatment against advice, and in twenty-four hours the trouble had begun to return. Another eight doses cleared up all inflammation, and she had no further recurrence. The fluid was not touched, and it gradually became absorbed while she was about her work as a trained nurse. The case had just been seen in time to prevent the formation of pus.

So certain is its action in aborting inflammation which has not reached the second stage, that when it fails within forty-eight hours to materially reduce the symptoms I commit myself to the diagnosis of the presence of pus and have no hesitation in saying so to the patient.

The following case of septic infection, seen in time to prevent pus formation, although the process had considerably extended, is interesting:—

Mrs. M—, æt. 47, had received a wound in her third finger of the right hand three weeks before being seen. The wound refused to heal, and the inflammation began to extend. When seen, the inflammation was well-marked on the dorsum of the hand, there was a considerable area of it on the ulnar side of the arm just below the elbow, above the elbow on the same side an abscess threatened, the axillary glands were inflamed, and pain was complained of on movement all down the right costal area. Cultures from the finger wound showed the presence of the staphylococcus pyogenes aureus and albus.

The finger wound was dressed with an antiseptic and ADS. was administered, 1,500 units every two hours for the first four doses, then 750 units 4tis hori. No other local treatment whatever was used, full dependence being placed on the serum. From the first there were decided signs of improvement which became more and more marked day by day. In four days she was practically well, and the treatment was continued in a modified form for two days more so as to confirm the result obtained. Seven days from the first dose she was dismissed absolutely well, all signs of inflammation having disappeared, and the finger wound having completely dried up. It need scarcely be added that the patient was something more than satisfied with the result.

The following teaches the lesson that it is false economy to discontinue the treatment too soon.

Mr. B—, æt. 37, is subject to severe attacks of quinsy, one of which was aborted by serum treatment. When the next attack came on it was twenty-four hours before serum was begun. In three days, however, the attack was aborted by 12,000 units, and the patient was dismissed. Three days later, the attack recurred, and went to pus formation in spite of vigorous administration of ADS. The serum being continued, pain was much relieved, the abscess was rapidly matured, and it was incised on the third day. Another 6,000 units at the first attendance would have saved the second attack.

Summary of Dr. Maclean's (Pollokshields, Glasgow) Case.

Mrs. T—, æt. 35, multipara, normal labour, placenta adherent and separated by hand; uterus flushed out; lochia scanty and sanious on third day, and ceased entirely on fifth day. Temperature was rising and respiration accelerated, and when lochia ceased there was abdominal distension without pain, but pain in left hypochondrium, and temperature was 102°. Four days later, there being dulness and friction

at the left base, she had a collapse, and in reaction temperature reached 103°. Next day dulness at right base. Treatment, antiseptic douching, poultices, and 20 c.c. antistreptococcal serum. Two days later condition was: Dorsal decubitus, acute pleuritis in both sides, crepitation and broncho-vesicular breathing at left base, dusky complexion, respirations rapid and shallow, profound intoxication with grave interference with vital functions. At this stage, twelve days' *post-partum* oral use of antidiphtheritic serum (special) was begun—1 dr. 4tis hori, also 10 min. doses of strychnine. From that time patient steadily improved in her general condition, and all her symptoms declined.

Six days later she began to menstruate normally both as to quantity and quality, and two days from its inception she complained of pain in left groin. This gradually extended down the leg, and was accompanied by swelling. It gave very little trouble and was completely cured in a fortnight. With it she had several slight attacks of vomiting. The temperature fell to normal eighteen days after serum was begun, and the pleural effusion, which consisted of a turbid serum, began to diminish three days later, and in a week had quite gone.

Dr. Maclean adds: "The serum . . . apparently did what was expected of it, namely, it supplied the patient directly with a means of resistance to the proteolytic action of the staphylococci and the toxic effects of the albumoses produced by the organisms, rendering her system a less suitable host for the bacilli and at the same time freeing, as it were, her tissues and organs to carry on their proper functions."

Dr. Wm. McLennan's Report.

Mrs. K., æt. 37, had abdominal section many years ago for recurrent attacks of localised peritonitis. The operation revealed extensive adhesions, which were separated as far as possible. Probably the seat of trouble was the appendix, which was so adherent that it was not removed. In October she complained of the onset of pain in the right side almost 2 ins. below the ribs (in nipple line). Pain increased and fever followed. For the first three weeks it was morning 99°, evening 100°. Then an acute rise took

place, with great increase of pain and temperature—morning 100°-101°, evening 101°-102° and over. There were rigors and sweats, and it was clear that great septic absorption was going on and probably pus formation. Operation was contemplated. "Paton's" serum was given at this stage, but the patient disliked the chloretone taste and could only be induced to take two doses a day for two days one or more of which she immediately rejected. On the third day serum was given regularly and in thirty-six hours temperature was normal and the patient on the high road to recovery. She has done well.

A few weeks later this patient showed symptoms of

a recrudescence of her trouble, and was at once given serum 1 drm. four times a day. In twenty-four hours all symptoms had disappeared, and Dr. McLennan reports the result as "very satisfactory."

When inflammation has reached the second stage and we have broken down tissue with pus formation, the conditions for serum treatment are entirely altered. ADS. will only act on living tissue, and hence it can only influence the collection of pus and *débris* by its action on the living tissues which are adjacent and affected by the extension of the inflammatory process. This process is limited in every case by the serum, and the usual foul condition is materially benefited and generally removed. According to the size of the abscess, the virulence of the infection, and the amount of tension in the cavity will depend how much can be done for the case. Depending then upon the proportion of each of these elements, ADS. will do good work in removing the surrounding inflammation and lessening the pain and other constitutional symptoms and by such work conserve the strength and comfort of the patient.

Pain, here, arises from two causes, one cause being tension outside and the other tension inside the abscess cavity. The first cause is removed by the serum, and where the tissues affected are loose in texture there is a very marked amelioration in this symptom. Mastitis is a very good example of this, for under ADS. this painful disease is robbed of most of its terrors, even when it has been seen too late and pus has formed.

The pain of tension in an abscess cavity is one that is not benefited by ADS. treatment, and it is probably increased by its use. The reason for this lies in the fact that where treatment has been begun too late to abort the attack the serum increases the reaction and raises the vaso-motor tension, causing increased exudation into the cavity, greater tension, and more pain. Where the structure of the tissues involved is of a firm and unyielding character, such as in periosteum and even a synovial membrane, the pain is increased by every dose shortly after it has been taken, and patients have of their own accord stopped taking it on account of this action.

There seems to be an exception to this rule, and that is in cellulitis of streptococcal origin. This was the character of the first case treated and its success started me out on this investigation.

Mr. B—, æt. 61, had been bitten on the hand by a cat and had a superficial erysipelas which easily yielded to treatment (bathing with spt. vini meth.). A week later he returned with a most acute cellulitis of hand and arm. The hand was swollen immensely, and the dorsum was tense, bright, and shining, while the arm was in a similar condition up to half-way between the elbow and the shoulder. He had all the symptoms of toxic resorption—headache, malaise, temperature over 100°, anorexia, &c. The first impulse was to incise the dorsum and give him an injection of anti-streptococcal serum, but to test the oral use of ADS. he was given 1,000 units in four doses, one dose every hour. Next day he had lost all his constitutional symptoms, temperature was 97°, head clear, a visible improvement in his hand, less pain, and able to move his fingers, which he could not do the previous day. After this, he would not allow me to use the knife on it, but demanded more of the same treatment. He had no other treatment except bathing it with spt. vini meth. He had the same dosage every day, the arm and hand steadily mended and he was discharged on the thirteenth day perfectly well. For some time he had stiffened fingers from tendons being fixed in remains of inflammatory processes. He still carries an exostosis on one of his metacarpals as a memento of the occasion. This was in March, 1898, and now he would get three times the quantity of the serum and be cured so much the more quickly.

As an example of the benefits to be derived from ADS. treatment where pus is present and before in-

cision, the following case of empyema is interesting. It is also a good example of the next stage.

Mr. C—, æt. 37, had pleurisy with effusion, which became empyematous. ADS. had been given too late to prevent the formation of pus, but in this case it so modified the constitutional symptoms that temperature was reduced to 100.4° and pulse to 84, while the patient ate and slept well. So well was he that a colleague, called in to chloroform for me while the tube was being put in, would not believe that pus of such recent origin was present in the case until convinced by aspiration. With the tube in, the treatment was continued, and he progressed steadily until it was thought that he was sufficiently well to do without it, and it was then stopped. In a day or two he began to show signs of relapse, and soon he had hectic night sweats, and increased discharge, which also gained an odour which became more pronounced day by day. His appetite and general health failed steadily, and he was rapidly going down hill. The treatment was resumed and the patient at once began to improve and continued to do so until in a short time the discharge had become so small that the tube could be removed and he made an uninterrupted recovery.

In this case even before the operation the symptoms were so ameliorated that it was difficult to believe that such a condition existed, and after it the recovery was due to the serum without any doubt whatever. In all, he used 46,000 units of ADS.

VI.—*The Elimination of the Products of Previous Processes.*—Generally, when free drainage is established, the recovery proceeds normally, but there are cases as in the examples given, in which the patient's resistance has become so enfeebled that his tissues are unable to resist the action of the organism even under the most favourable conditions, and the process is continued indefinitely. The addition to such cases of the tissue resistance supplied by the appropriate serum enables normal condition to be attained and normal results being seen. In this condition the following case illustrates the difference between simple plasma and the antidiphtheritic serum.

A. T., æt. 53, had been suffering from acute cellulitis above and below the elbow for several weeks. There were six incisions all discharging pus freely, while from his temperature and appearance there was considerable absorption. Under ADS. the whole condition rapidly improved, temperature fell, pus discharge rapidly lessened, sleep and appetite with clean tongue returned, and he was doing well. Before the case was quite right, simple plasma was substituted for the antidiphtheritic with the result that the case promptly relapsed, pus discharge increased, temperature rose, absorption again showed itself, all within a week. On resuming ADS., the whole of the symptoms rapidly disappeared, and in three days all but one sinus had ceased discharging. Further treatment on the same lines led to recovery. It was clear that in ADS. there were elements and capacities not found in normal serum.

Dr. Alex. McLennan's (Glasgow) Cases.

VII.—*Stage of Continued Suppuration after Pus has been drained (two cases).*—M. M., was operated upon for an empyema on October 23rd, 1905. The previous condition had been pneumonia (?) without a crisis. From October 3rd, the operation temperature had varied from 99° F. to 104.4° F. For three and a half days it had been between 99.2° F. and 100° F. After operation it ranged daily between 99.2° F., 103° F., and 103.8°. Serum was begun on November 2nd. Previous evening temperature was 103° F.; on November 2nd, 101.4° F. November 2nd to November 6th, temperature ranged from normal to 99° F. November 6th, serum stopped; November 6th, 8 p.m., temperature 100.4° F. November 7th, temperature 101.4° F. Serum begun after this on November 7th. Since then temperature has ranged from normal to 100.4° F. The pulse which has been rapid has varied

with the temperature. There are obscure abdominal symptoms. A coverglass preparation of the pus from the empyema showed numerous cocci, in groups and few in short chains; no culture was taken.

The general condition has improved with the decline in temperature and pulse rate. This patient went on to perfect recovery under reduced dosage.

Dr. McLennan also reports a case of pyelitis with temperature ranging to 105° F. the night before serum was begun, fell as per chart, while serum was being administered. This gave an opportunity for nephrectomy, which was successfully performed, and the patient did well. The operation was necessary for causes extraneous to the kidney.

MERCURIAL INJECTIONS IN THE TREATMENT OF SYPHILIS.

Synopsis of the Discussion at the Medical Congress held at Paris, 1905.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

The preference to be given to the administration of mercury by hypodermic injection rather than by the mouth or by inunction is a big question, and in order to enable our readers to grasp the situation we cannot do better than place before them a *resume* of the arguments advanced at the last Medical Congress in Paris, in which Drs. Julien, Hallopeau, Abadie, Leredde, Fournier, and others took part.

The hypodermic method of administering mercury is of comparatively recent introduction, that is to say, it only dates back some forty years. It was in 1863 that Hebra and Hunter called attention to the possibility of treating syphilitics by injections of corrosive sublimate. In 1864 Scarenzio, to whom the credit of introducing it was really due, began to make use of calomel in suspension. At present mercurial injections have come into general use, but like all active medications they may be productive of mischief unless carefully handled, so that it behoves the practitioner to make himself conversant with the indications and with the technique.

In some instances attempts have been made to obtain the purely local effects of the drug by injecting it in the immediate vicinity of the damaged tissue, as, for instance, in Professor Bouchard's method of injecting small doses locally, the advantage whereof is best seen in ophthalmological practice by subconjunctival injections, and in Mr. Sicard's sub-arachnoid injections in neuropathology.

It is, however, especially as a means of obtaining the constitutional effects that mercurial injections are usually employed. There are two principal methods of administering the drug, one by the method of daily injection of the same, or a progressively increasing dose of the drug calculated to satisfy the requirements of the syphilitic organism; and the method of periodical injections of insoluble salts which are deposited in the tissues at regular intervals, thus supplying a certain quantity to be utilised by the organism at its leisure.

MERCURIAL PREPARATIONS FOR INJECTION.

Soluble Preparations.—These comprise principally the biniodide, the benzoate and the perchloride of mercury.

1. *Perchloride of Mercury.*—Drs. Barthelemy and Levy-Bing recommend the following formula:—

Hydrarg. perchloridi, 0 grms., 10;
Pulv. sodii chlor. pur., 0 grms., 075;
Aqua dest., 10 grms.

The chloride of sodium has the advantage of rendering the injections less painful, and there is no reason why the proportion of this salt should not be increased. In Germany they employ the following:—

Hydrarg. perchloridi, 1 grm.;
Sodii chloridi, 10 grms.;
Aqua dest., 100 grms.

One cubic centimetre of either of these solutions represents one centigramme of the sublimate, an average daily dose. In some cases, however, this dose is not sufficient, and the injection may be increased advantageously to two centigrammes daily for twenty days, carefully watching the state of the mouth, intestines, &c.

2. *Benzoate of Mercury.*—Stoukowenkoff's formula is:

Oxybenzoate of mercury, 0 grm., 30;
Pure chloride of sodium, 0 grm., 10;
Muriate of cocaine, 0 grm., 15;
Distilled water, 40 grms.

This solution requires to be freshly prepared, as the cocaine precipitates the mercury in a few days.

Another solution, recommended by Bretonneau and Desesquelle:—

Benzoate of mercury, 0.60 to 3 grms.;
Cocaine, 0 grm., 12;
Benzoic acid, 0 grm., 60;
Distilled water, q. s. to make 60 cc.

A simpler formula is the following:—

Benzoate of mercury, 1 grm.;
Pure chloride of sodium, 0 grm., 75;
Sterilised distilled water, 100 grms.

One centigramme (about a sixth of a grain) of benzoate of mercury is a small daily dose, and we may safely give two centigrammes daily for three weeks. Gaucher, however, considers this a large dose, though other authorities advise the drug being pushed to three and even four centigrammes daily.

3. *Biniodide of Mercury.*—This can be injected in an oily solution by Panas' formula:—

Biniodide of mercury, 0 grm., 40;
Purified sterilised olive oil, 100 grms.

This solution contains four milligrammes in each cubic centimetre—rather a small proportion, necessitating, therefore, the injection of at least two cubic centimetres.

By dissolving the biniodide in walnut oil, washed with alcohol and sterilised, it is possible to obtain a solution containing ten milligrammes per cubic centimetre, and by mixing equal quantities of this oil and castor oil, the proportion can be raised to fifteen milligrammes per cubic centimetre.

Biniodide of mercury, 1 to 1.50 grms.;
Oil of walnut treated as above, 50 cc.;
Sterilised castor oil, 50 cc.;

to be dissolved at a temperature of 70° C.

This biniodised oil must be kept in coloured phials and not exposed to light, and on the whole it is preferable to make use of freshly-prepared solutions. The injection is not absorbed as rapidly as, and is more painful than, aqueous solutions, consequently the latter are generally preferred when intended for daily pro-

longed use, although their action is less pronounced.

The following is a watery solution of the biniodide:—

Biniodide of mercury, 0 grm., 20 ;

Iodide of sodium, 0 grm., 20 ;

Distilled water, 10 cc.

The daily dose for three weeks' treatment is one cubic centimetre—two centigrammes. The dose may gradually be increased to three or four, or even five centigrammes.

The addition of iodide of sodium increases the solubility of the biniodide. Instead of distilled water we may employ a 75 solution of chloride of sodium.

Biniodide of mercury, 0 grm., 20 ;

Iodide of sodium, 0 grm., 20 ;

Chloride of sodium, 0 grm., 0.75 ;

Distilled water, 10 cc.

4. *Cyanide of Mercury*.—This is very active in a 1 per cent. solution, and it does not occasion much pain. We shall show later that the cyanide and the oxycyanide are specially indicated, when we propose to make intravenous injections.

INSOLUBLE PREPARATIONS.

These preparations are composed of calomel or metallic mercury in the form of grey oil (*huile grise*). The usual formula is the following:—

Sublimed calomel, 1 grm.;

Pure liquid vaseline, 10 cc.

Vaseline oil is an excellent vehicle, being perfectly stable; it has, however, the drawback of causing irritation in certain subjects. Pure olive or sweet almond oil would no doubt be better, but they do not keep well. Dr. Balzer suggests a mixture of equal parts of liquid vaseline and olive oil. In making the injection the bottle must be well shaken in order to secure the proper proportion of calomel.

For metallic mercury we may select one of the three following:—

Mercury ;

Lanoline, aa 3 parts ;

Rectified olive oil, 4 parts (Lang) ;

Metallic mercury, 20 grms.;

Lanoline, 5 grms.;

Vaseline, 35 grms. (Brousse and Gay).

Purified mercury, 40 grms.;

Anhydrous sterilised lanoline, 12 grms.;

White sterilised vaseline, 13 grms.;

Sterilised liquid vaseline, 35 grms. (Lafay).

One cc. contains half a gramme of mercury.

The average weekly dose of calomel is 10 centigrammes, and of mercury 7 or 8 centigrammes, and from 40 to 50 centigrammes for the complete treatment.

As the injections of insoluble salts are made once a week, the usual dose will be 1 cubic centimetre of the above calomel solution, equal to 10 centigrammes of the salt, and a seventh of a cubic centimetre of grey oil, equal to 7 centigrammes of mercury.

THE MODUS OPERANDI.

Mercurial injections must never be made subcutaneously, on account of the pain and the inflammatory nodules they provoke. The injections should be made deeply into the muscle substance either in the spinal furrow or into the gluteal region, taking care to avoid the sciatic nerve. Every antiseptic precaution must be observed, the injection should be made deeply, and before emptying the syringe it is well to ascertain that no blood is escaping through the needle, in order to avoid the possibility of an embolism. The patient should be lying down. After the injection the part should not be massaged, but simply dressed with collodion. Under these circumstances it is hardly necessary to insist upon the fact that these injections must of necessity be left in the hands of the surgeon.

It is absolutely necessary when making use of mercurial injections to keep an attentive eye on the patient's mouth and on the intestinal functions. Mercury is known to cause stomatitis and enterocolitis, consequently the treatment must be suspended whenever there is pyalism, salivation or diarrhoea. Stomatitis, however, may be caused even with small doses

if the patient's mouth be in a bad state, consequently before commencing the treatment the teeth should be attended to, if required, and the patient must be enjoined to pay great attention to keeping the mouth in a hygienic condition.

With the soluble preparations it is customary to inject for some twenty days following; for the insoluble preparations one injection a week for five weeks.

The intravenous method has recently been recommended. For that purpose we make use of solutions of the cyanide or oxycyanide, because they do not coagulate the blood. The following solution may be used:—

Cyanide of mercury, 1 grm.;

Distilled water, 100 grms.

One cubic centimetre is injected daily, equal to 1 centigramme of the cyanide.

Intravenous Injections appear to act very promptly; they are easy enough in spare subjects whose veins are readily accessible, but are more difficult in women. It is necessary to insist on the extreme importance of absolute asepsis.

Drawbacks and mishaps with mercurial injections.—

Reference has already been made to the sometimes very sharp pain that follows the injection, especially of the insoluble salts. In spite of every precaution, aseptic abscesses sometimes follow the injection of insoluble salts; indeed, they have been accused of causing the death of the patient, but such fatal cases as have been recorded were probably due to too large doses, to the debility of the subject or to mere idiosyncrasy. If the treatment be unduly prolonged the patient loses weight, and his general nutrition suffers. It is therefore a good plan before commencing the treatment to weigh the patient, and to repeat the process from time to time. So long as the weight remains stationary or increases the treatment may be continued, but should the patient lose flesh, the treatment should be suspended, or, at any rate, modified.

INDICATIONS FOR INJECTIONS.

Some authorities, among them Dr. Hallopeau, hold that mercurial injections are not to be recommended in general, and that they should only be had recourse to in severe cases. He says: "These injections may give rise to intolerable pain, to aseptic abscesses, to fever and to pulmonary embolism. On several occasions they have caused death, even when carried out with every possible precaution. On the other hand, it has been shown that the method does not invariably present the superiority of action claimed for it." Dr. Hallopeau substantiates his view by the case of a patient who had an acute generalised papulo-tubercular eruption within a few days of a prolonged treatment by the benzoate of mercury, and that of a man who developed gummata in the very arm where the injections had been made. He suggests that inunctions might very well yield equally good results, especially if made on the hairy parts. The injections, moreover, are very costly for the patient, and this is a reason for abstaining from recommending them unless clearly indicated. His present practice is to order injections of the insoluble salts in threatening cases, especially at the onset of tabetic symptoms, and he gives the preference to grey oil, the action whereof is slower on account of the fact that it takes time for the lymphocytes to absorb the molecules of calomel. Apart from these cases, injections should only be employed if the patient for any reason cannot or will not consent to inunctions, and even in such cases it is well to try what can be done by administering mercury by the mouth.

Most authorities, however, consider the method of mercurial injections to be by far the most active and trustworthy plan, and they devote their attention to pointing out the indications and the reasons for preferring the soluble or the insoluble salts. It is generally admitted that the intramuscular injection of insoluble salts is much more active than that of the soluble salts, but on account of the greater number of drawbacks

which the latter present they should only be employed in special cases.

Professor Fournier, at the Medical Congress at Paris in 1904, formulated the following indications for the use of the insoluble salts: The daily injection of the biniode or the perchloride is, he says, good treatment, the action whereof may be compared with that of pills and inunctions. But it is not an extremely active treatment. That remark, however, does not apply to the weekly injection of grey oil in large doses. This treatment by the injection of insoluble salts is not an exceptional treatment; it is a treatment to be adopted in presence of certain indications, and these indications may be grouped as follows:—

- (1) Phagedenic chancres; (2) tertiary phagedænis; (3) dry tubercular syphilides or tuberculo-crustacea; (4) gummatous laryngitis; (5) palmar and plantar psoriasis; (6) syphilitic lesions of the tongue.

In threatening cases, as in gummatous laryngitis, and in case refractory to other methods of treatment, such as palmar and plantar psoriasis, the injection of the insoluble salts often gives quasi-miraculous results. Calomel acts specially well in lesions of the tongue.

So much with regard to the indications for the use of the insoluble preparations. We will now proceed to the discussion of the employment of mercurial injections in special cases.

Infantile Syphilis.—Insoluble preparations are dangerous in the young, who, however, readily tolerate the benzoate and the sublimate. But, employed in 1 per cent. solutions, of which from $\frac{1}{4}$ to 1 cubic centimetre is injected daily, or every other day, they entail an assiduity of treatment that cannot always be obtained. To obviate these inconveniences Dr. Imewol, of Jassy, recommends Lukaszewicz' method, which consists in making one injection weekly of a 5 per cent. solution of the sublimate. He employs the following solution:—

Chloride of sodium;
Perchloride of mercury, aa 0 grm. 50;
Sterilised distilled water, 10 grms.

This contains 0 grms., 05 centigramme of the salt in each cubic centimetre, and therefore 5 milligrammes to each division of a Pravaz syringe. In the very young the strength of the solution is reduced to 2 per cent., so that each division of the syringe contains only 2 milligrammes of the active substance.

Perchloride of mercury;
Chloride of sodium, aa 0 grm. 02;
Sterilised distilled water, 10 grms.

These are the doses according to the age of the subject:—

Between one and three months, from 0.002 to 0 grm. 004; from three to twelve months, from 0 grm. 005 to 0 grm. 010; between one and two years, from 0 grm. 010 to 0 grm. 020; at three years, from 0 grm. 020 to 0 grm. 025; between four and six years, from 0 grm. 020 to 0 grm. 030; between six and twelve years, from 0 grm. 025 to 0 grm. 040.

One always begins with the smallest indicated dose, gradually increasing it, according to the tolerance of the child and the refractoriness of the manifestations, until the maximum dose is reached. The injection is made once a week, or every five days, in serious cases, and the treatment is continued until the subsidence of the manifestations.

The sublimate solution must be clear, and should it become turbid it must be discarded. After the injection, the interior of the needle must be cleansed in order to remove the black deposit left by the sublimate. Needles of irido-platinum are preferable to steel needles, since this metal is not attacked by the salt. Dr. Imewol usually obtains a cure after from three to five injections, but rarely has he found it necessary to go as far as six, and the latter number he has never exceeded.

Ocular Syphilis.—According to Dr. Abadie, intravenous injections (of the cyanide or oxycyanide) are specially recommendable in ocular syphilis. In slowly developing irido-retino-choroiditis, and in cer-

tain varieties of late optic atrophy, inunctions, pills and intra-muscular injections often fail and intravenous injections alone can save the patient. In senile syphilis contracted after sixty years of age the eyes always suffer early, and intravenous injections alone can save the patient's sight. When for any reason we cannot have recourse to intra-venous injections, Abadie advises recourse to intra-muscular injections of large doses of the biniode or cyanide of mercury (from 2 to 2½ centigrammes).

Syphilis of the Nervous System.—In these cases, especially where there are cerebral lesions, such as syphilitic cerebro-spinal meningitis, cerebral tumours, &c., injections are to be preferred, but in acute syphilitic meningitis all mercurial preparations seem to act well, however employed. In cerebral gummata we must have recourse to the mixed treatment. Fournier recommends iodide of potassium internally in average daily doses of 5 grammes, with the inunction of from 5 to 10 grammes of mercury daily. Mercurial injections seem to be more active, and the soluble preparations are usually employed. Syphilitic cerebral arteritis is one of the manifestations of syphilis on the nervous system that most readily responds to the injection of soluble salts of mercury. In syphilis of the medulla the action of mercurial injections is by no means uniformly favourable.

Nevertheless, in view of the good effects of mercury in some few cases we are justified in cautiously trying the effect of mercury, and for this purpose pills for inunctions, or the injections of soluble preparations should be resorted to.

CLINICAL RECORDS.

CASE OF CEREBRAL TUMOUR.*

*Under the care of LEONARD GUTHRIE, M.D.,
Physician to Paddington Green Children's Hospital, etc., etc.*

W. K. (M.), clerk, æt. 29, admitted to hospital October 24th, 1905, with right-sided hemi-paresis and double optic neuritis. Seven years ago he contracted syphilis, for which he was under treatment 3 months. No obvious secondary symptoms, but health never good since. Complained of "general deterioration, mental and physical." Fifteen months ago the patient noticed gradual weakness of right arm and leg, which increased until he had to give up employment owing to inability to write or hold his pen properly. Slight headaches at times, but no vomiting.

On admission, optic discs showed double neuritis most marked in left. Condition resembling "choked disc," without much swelling. V. fields contracted especially left. V.—L.—6-9 R. 6-6. Pupils reaction normal. Ocular movements normal. No paralysis of facial nor other cranial nerves. Speech rather hesitant and slurring. Slight tremor of lips. Right hand grip weaker than left. Clumsy in executing precise movements—e.g., buttoning clothes. Condition more ataxic than paretic. Right leg spastic, slight talipes equinovarus. All movements against resistance in R. leg weaker than in left. Nutrition and sensation normal. All tendon reflexes active and greater on right than on left side. Ankle clonus absent. Plantar response extensor on R., flexor on L.

Progress.—After admission, optic neuritis and contraction of fields increased. On November 3rd, slight epileptiform seizure occurred with general convulsions, but no focal commencement. Loss of consciousness, tongue not bitten, urine not passed. Duration about ten minutes. On November 8th, two more attacks in which he became dazed and stupid but without loss of consciousness. No fits before nor since. Treatment by iodides pushed until by mid-December he was taking 50 grains of mixed iodides t.d.s. Swelling of the left disc then began to subside, that on the right remaining

*Notes of a case shown at the Harvelian Society, January 25th, 1906.

in statu quo. Slight iodism, soreness of eyelids and a few spots. Iodides then gradually reduced to 24 grains of mixed salts t.d.s.

Patient has improved in general health and has gained weight. Hand movements have become less ataxic under treatment by exercises. He now writes fairly well, though slowly. The gait is less spastic.

Diagnosis.—Gumma probably supra-cortical in mid area of left cerebral hemisphere.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Rodent Ulcer.

By G. LENTHAL CHEATLE, C.B., F.R.C.S.

AMONGST the out-patients was a female at 32 years, a case of rodent ulcer on the back, sent to Mr. Cheatle by Dr. Arthur Whitfield, not for diagnosis or treatment, but for him to see and record among his cases of rodent ulcer on the body. Mr. Cheatle said that Dr. Whitfield knew that was a case of rodent ulcer because he had removed a piece of the tumour's edge for purposes of diagnosis. Rodent ulcers on the body were rare compared to the frequency of their appearance on the face. He (Mr. Cheatle) had so far been able to collect pictures of 19 cases, that case making the 20th. However, there were a few more recorded cases, of which he could not get pictorial records.

Squamous epithelioma on the body was rarer still. He had only seen two cases, one of which had two separate growths, one on the shoulder and the other over the posterior superior iliac spine.

The case before them, Mr. Cheatle said, was the 12th case among rodent ulcers which had begun on the back, compared to 8 which had appeared on the front of the body, and it was the third which had appeared in this region, namely on the skin covering the posterior aspect of the upper border of the trapezius muscle. Those three cases were females. He could not find any mechanical cause why rodent ulcers should appear at this point in females. Females did not wear braces. Had these three cases been men the cause for this common point of incidence could have been explained as one due to the mechanical irritation of the brace. That woman could not give them any reason to suppose that so gross a mechanical irritant was etiologically connected with the incidence and genesis of that tumour.

In the *British Medical Journal*, April 29th, 1905, he had pointed out that that was a point of incidence common to leucoderma and scleroderma, and it was known that those two diseases were pretty generally believed to be neurotrophic in origin and spread. He ventured to suggest that the incidence and spread of cancer was also closely connected with the same influence. The peripheral nerves, upon whose distribution those three rodent ulcers appeared were the acromial branches from the cervical plexus. The skin on either side of the spinal column from the vertebra prominens to the tip of the coccyx was another favourite area of incidence for rodent ulcers, leucoderma and scleroderma.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

ENUCLEATION OF A TUMOUR FROM THE NECK OF THE HUMERUS.—Mr. A. CARLESS operated on a man, at 30, who had been brought to the hospital ten days previously complaining of pain and swelling in the right shoulder. His story was that when he was riding in a covered van in the erect posture, the van gave a lurch and he laid hold of a strap above his head to steady himself, and to prevent himself from falling he had to make a sudden jerk with his arm in the "strap-hanger" position. Sudden and severe

pain was felt and all subsequent movements of the arm were painful. On careful examination a few days later, the shoulder was swollen, but no evidence of a dislocation could be detected, although a definite lump could be felt in the axilla, which somewhat suggested a sub-glenoid dislocation. On manipulation slight crepitus was obtainable in some movements. The existence of a fracture of either the anatomical or surgical neck of the humerus could be negatived, as also fractures of the clavicle or of the body of the scapula. It was thought that possibly there was a fracture of the lesser tuberosity or of the coracoid process. On radiographic examination, it was found that the head of the bone was *in situ* and that no ordinary fracture was present. An oval shadow was seen encroaching on the inner half of the neck and the adjacent portion of the humerus and projecting inwards and downwards to a somewhat greater extent. It seemed possible that this might be the lesser tuberosity pulled off and drawn inwards; but this supposition was negatived by observing that the supposed fragment would have been displaced downwards as well as inwards, a direction in opposition to that of the axis of movement of the sub-scapularis muscle; moreover, the compact tissue of the humerus was continuous with that on the outer aspect of the lump, and there was no solution of continuity observable, whilst the inner margin of the lump was constituted by a definite line of thickened bone. Under these circumstances, it was obvious that the lump which could be felt in the axilla was the lower end of a tumour involving the upper end of the humerus from and into which it grew. Its invasion of the neck of the humerus showed that it could not be an exostosis, and Mr. Carless considered that the diagnosis probably lay between a chondroma and a sarcoma, and that the growth was probably cartilaginous in type as it is unusual for a sarcoma to be limited by a layer of sclerosed bone. After thorough purification of the arm and shoulder, an incision was made parallel to the lower border of the pectoralis major, opening up the axillary connective tissue and extending down to the biceps tendon. A little dissection demonstrated that the lump was connected with the humerus, and that the crepitus was in the substance of the tumour, which projected forwards between the subscapularis above and the tendon of the teres major below. To remove the growth it was found necessary to make more room by dividing the pectoralis major muscle; this was done by an incision at right angles to the former. It was then possible to define the limits of the growth, which was freely gouged away. It was found to extend into the bone and in order to ensure its complete removal the shoulder joint had to be opened and part of the cartilage covering the articular surface removed. The bone exposed by the removal of the growth was firm; it was thoroughly scraped and well swabbed over with liquefied carbolic acid, the excess of which was subsequently washed away by alcohol. A drainage tube was introduced, the pectoralis major muscle firmly sutured and the wound closed. Mr. Carless commented on the interesting nature of this case, emphasising particularly the fact that the crepitus which had been detected was due to a fracture of the bony tissue contained within the tumour. As to the nature of the tumour, it was of a soft, somewhat friable consistency, reminding him, he said, more of a parotid tumour than anything else, and he thought it quite possible that on microscopical examination the growth might turn out to be an endothelioma.

It is satisfactory to record that the wound healed perfectly, and that the patient is already, ten days after operation, able to move his arm inwards and outwards.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

MEETING HELD FRIDAY, JANUARY 19TH, 1906.
The President, Sir WILLIAM SMYLY, M.D., P.R.C.P.I.,
in the Chair.

THE DIAGNOSIS, TREATMENT, AND PATHOLOGY OF EMPYEMA.

A DISCUSSION on the diagnosis, treatment, and pathology of Empyema was introduced by Dr. W. G. Smith, Sir Thornley Stoker, and Dr. Earl.

Dr. WALTER SMITH opened the discussion. His remarks referred chiefly to etiology and diagnosis. As to nature of effused fluids, it is sufficient to group them into (a) sero-fibrinous; (b) purulent. The main advance in etiology is the firm establishment of the doctrine that most pleuritis are due to, and are caused by, infective agencies. Three points may be noted:— (1) The serious significance of the tubercle bacillus; (2) the comparatively favourable outlook of even purulent effusions when due to the pneumococcus; (3) the serious and frequently fatal character of cases due to acute streptococcus invasion. In regard to physical diagnosis, half-a-pint is about the smallest quantity that can be recognised. Percussion is more valuable, diagnostically, than auscultation. Damoiseau's parabolic curve of dullness can often be made out. Bronchophony may be heard through a considerable mass of pleural fluid. Vocal fremitus may be normal, or, even *weakened*, in acute pneumonia, and is often increased just above upper limit of an effusion. Exploratory puncture is the most valuable and certain mode of detecting fluid. Special attention was drawn to the problem of intra-pleural pressure, and a brief summary was given of our present state of knowledge. Stress was laid upon the prime importance of the elasticity of the lung as the chief and essential factor to be considered. Even with the most powerful expiration, the pleural pressure remains negative. In presence of effusion, we have no right to consider positive pressure until and after the elasticity of the lung has been exhausted. Then, and then only, does true compression of the lung begin. Measurements of pleural pressure in cases of effusion give discrepant results, which are not yet susceptible of complete explanation.

Sir THORNLEY STOKER introduced the discussion on the Surgical Treatment of Empyema, and gave the results of his own experience as to various methods. He laid great stress on the early drainage of the pleural sac, and set aside as quite out of date the use of aspiration. He strongly advocated that when thoracotomy is called for, it should not be practised by intercostal incision, but by removal of a portion of a rib. He claimed that this should be the routine method, as it gives room for digital exploration, avoids the pinching of drain-tubes between the ribs, can be conducted more cleanly, is free from risk of bleeding, permits the discharge of the large masses of lymph usually found, and can be practised with great rapidity. He advocated the performance of thoracoplasty at a period anterior to that at which it is often resorted to, and claimed that when done in time, without delaying to the last moment, and when performed in a certain way, it is not a very serious proceeding and is usually a very successful one. The U-shaped flap should be avoided, and the portions of ribs operated on removed through straight incisions parallel to their axes. One incision sufficing for the resection of portions of as many as three ribs. He stated that in his practice he had not found removal of the periosteum necessary; it increases the length and danger of the operation, and the membrane causes no ill effects if left behind. Irrigation of the pleural sac is to be avoided in most

cases, and only resorted to if foetor is present, or discharge unduly persistent. It is often dangerous to life by causing collapse or convulsions. Of methods ancillary to operation, and intended to assist the closure of the pleural cavity by helping the expansion of the lung, he advised positive pressure, by respiratory gymnastics, such as forced inspiration and expiration, or the blowing of water from one large bottle to another by James's plan. The introduction of condensed air into the lung has often been found dangerous. Of negative pressure, he could only say that he did not see how it could be made practically available in a vital and restless machine like the human body. Finally, he forecasted in the near future an assistance to our present means, or even a supersession of them to some extent, by the studies of the uses and actions of bacterial vaccines, and of the opsonic powers of the blood, at present being pursued.

Dr. EARL read a short paper on the Bacteriology of Empyema. He pointed out the importance for prognosis that bacteriological examinations have particularly in cases of pneumococcal and streptococcal origin. He also discussed the difficulty of diagnosis of the nature of tubercular cases, and the value to be attached to the sterility of an effusion.

Sir JOHN MOORE read notes of two cases illustrative of the difficulties which attended the differential diagnosis of empyema, or pyothorax and hypophrenic abscess. In the first case, that of a woman, *et. 30*, the physical signs led to a diagnosis of right empyema. Paracentesis was performed, and 170 ounces of most offensive pus were drawn off. The patient sank, and at the autopsy the seat of suppuration proved to be altogether below the diaphragm, constituting a hypophrenic abscess, and involving the liver also. The starting point of all the mischief was probably a perforating gastric ulcer, in connection with which adhesive inflammation had occurred. In the second, a man, *et. 52*, suffered from cancer of the oesophagus. He complained of difficulty of swallowing, sharp pain in his chest, and spasmodic cough. Exploration of the right pleura showed a serous effusion. He subsequently grew worse. The right side of the chest became immobile, the lower interspaces were effaced and there was local oedema. A syringe of stinking pus was drawn off from the right side in the seventh intercostal space. Mr. Taylor afterwards excised a portion of the right tenth rib, in a line with the inferior angle of the scapula, and evacuated an enormous collection of very foul-smelling pus. The man died three days later, and the *post-mortem* showed that a perforating cancer of the oesophagus had opened into the posterior mediastinum, thence reaching the right pleura and setting up a septic empyema. The examination of the abdomen revealed nothing abnormal.

Sir ARTHUR CHANCE said that the policy of surgery towards empyema was very simple. Early efficient drainage, expansion of the lung, and, if necessary, a contraction of the chest wall by surgical means, with possibly removal of diseased pleura, were the simple surgical indications; but to carry them to a successful issue was very difficult, and one was confronted by the difficulty of the different varieties of empyemata. He preferred to open the chest wall lower down and further back than Sir Thornley Stoker had advocated, and he believed in a particularly short skin incision. He agreed as to the wisdom of always removing a portion of the rib, and he always used a very large drainage tube. The records of thoracoplasties was not very good, but perhaps this was due to delaying too long, &c. He thought Estlander's operation open to the objection that it left behind a very large thickened pleura, and he was inclined to remove not only rib, but the intercostal structures and parietal pleura. The operation to be done in stages. Empyemata might be divided into three varieties: The class

following pneumonia, which got well with moderate care, efficient drainage, &c. The neglected class, in which the prognosis was fairly good. The tubercular class, in which the prognosis was very bad indeed.

Dr. A. C. O'SULLIVAN gave particulars of the opsonic power of the blood and pus from two cases of empyema.

Dr. HAYES showed four cases illustrating the good effect after operation done up to ten years previously. He pointed out that formerly irrigation was always carried out, but this was never done now. He relied on puncture with a long needle as the best aid to diagnosis, and thought the severe operation recommended by Sir Arthur Chance unnecessary, as his cases showed that the thickened pleura had resolved.

Dr. NINIAN FALKNER submitted, from the Registrar-General's statistics, a tabular statement of the ages of those whose deaths had been attributed to empyema in 1904, and of the associated conditions.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD JANUARY 19TH, 1906.
Dr. PORTER PARKINSON in the Chair.

Mr. ARTHUR EDMUNDS showed a case of "Cutaneous Pigmentation," showing on the buttocks and back a curious bluish mottling similar to the pigmentation in a large number of Asiatic races of mixed descent. The pigmentation resembles that shown in a Japanese baby recently exhibited at the Society by Dr. Sutherland. Much discussion has been caused by this pigmentation, some holding that it is an evidence of a negroid ancestor, while others, especially the Japanese authors, hold that it is merely a racial characteristic. In the present case there is no history of any negroid ancestry.

Dr. GEORGE CARPENTER showed a case of "Sclerema neonatorum" in a girl of 8 weeks. The child was well nourished and healthy-looking, weighed 20½ lbs.; there was no cyanosis. There was a brawny induration of a pinkish purple hue over the whole of the back and back of the neck, also over the buttocks and upper part of the thighs posteriorly; also two small patches over the occipital region of the scalp.

Dr. PORTER PARKINSON showed microscopic specimens from a case of "sclerema neonatorum" taken from an eight-months infant, who died when 10 days old. The sections of the skin showed chiefly thinning of the epidermis with considerable thickening of the cutis vera, apparently due to increase of fibrous tissue, but this seemed insufficient to account for the sclerema which, the exhibitor suggested, was due to a chemical rather than a structural change.

Dr. LEONARD GUTHRIE showed a case of "Lipomatosis" in a very fat child, but neither weight nor height was abnormal, the discrepancy between weight and appearance being probably due to lightness of skeleton. The obesity appeared to be a morbid condition, not a mere "normal abnormality." Possibly there is a connection between deficient thyroid development and lipomatosis, whilst in the latter lessened oxidation owing to the cardiac condition may play a part. Dr. Guthrie suggested that the case might be one of arrested development with obesity.

Dr. C. O. HAWTHORNE showed (1) two children with Mental Defect and Optic Nerve Atrophy, and (2) a boy, æt. 7, who had almost completely recovered from an Infantile Hemiplegia which followed a convulsive seizure at two years of age.

Dr. GEORGE CARPENTER and Mr. LOCKHART MUMFORD showed a case of Hemihypertrophy in a child of 2½ years, the left side being larger than the right. The face and tongue on the affected side were appreciably larger, and the head was half an inch broader. The left side of the trunk was one inch larger than the right, the left arm half an inch longer, and the left leg one inch longer and correspondingly enlarged. The bones on the hypertrophied side were also larger.

Dr. GEORGE CARPENTER showed a boy, æt. 18 months, who had a soft, freely movable, elastic swelling the diameter of a 2s. piece in the breast, which had been noticed since birth. Latterly it had decreased a little in size. The contents on exploratory puncture resembled milk and were micro-chemically of that nature.

Dr. GEORGE CARPENTER showed a specimen of congenital hypertrophic stenosis of the pylorus, which had been removed from an infant of four weeks. It was born healthy, but persistently vomited immediately after nursing, ever since birth. A tumour the size of the terminal phalanx was felt during life in the neighbourhood of the pylorus. An attempt was made to feed the infant by simple milk dilution, next by a mixture of whey and cream, and then by whey with a fat substitute for the cream, but unsuccessfully. The child vomited and lost weight in spite of the dietary and despite stomach washings, rectal injections of normal saline and minute doses of opium. Albumin water caused the least gastric disturbance. Gastrojejunostomy was performed by Mr. Ewen Stabb, but the infant could not withstand the shock of the operation, and died six hours afterwards.

Dr. GEORGE CARPENTER and Dr. THEODORE FISHER read notes of a case of fatal dilatation of the heart occurring in a boy, æt. 8, in which after death there was no adhesion of the pericardium and no valvular disease. Apparently he had suffered from symptoms indicating cardiac failure from about 1 year, but the only history of rheumatism was of an attack four months before admission. After death the heart was found to be not only dilated but hypertrophied. It weighed 10½ ozs. Microscopically there was considerable fatty degeneration of the cardiac muscle, but this probably was a comparatively recent pathological change.

Mr. ARTHUR EDMUNDS showed a case of successful removal of a congenital sacral tumour.

The tumour had been present from birth, but the mother thought that it was slowly, but steadily increasing in size. It consisted of two distinct parts; one of which was distinctly solid, while the other was definitely cystic. The former was situated slightly to the right of the middle line, overlapping the right sacro-iliac synchondrosis. The skin over it was slightly more hairy than the rest of the body, but otherwise it was quite normal. The tumour itself was about the size of an orange, firmly fixed to the skin, while a fair amount of mobility could be obtained on the deeper tissues. The specimen exhibited shows a section of the whole tumour and the terminal part of the coccyx. The solid portion is seen to consist of fat pervaded by coarse strands of fibrous tissue. In one place a small bone was found with cartilage covered ends. The section shows a small nodule of cartilage. Running through the centre of the tumour there is a branched tube containing the small fatty epithelial balls, which are characteristic of dermoid tumours.

Dr. J. G. EMANUEL (Birmingham) showed an infant with Congenital Absence of the Skin affecting the hands, legs, and feet. In addition, over the temples, the bridge of the nose, and the middle of the lumbar region there were irregular shaped areas in which a similar congenital deficiency in the formation of the epidermis existed. The parts affected were smooth, free from hair, sharply defined from the neighbouring healthy skin, and transparent, so that the delicate underlying blood vessels were clearly visible. The infant was born dead at full term. Microscopic examination of sections showed that the defect consisted of a complete arrest of development of all layers of the epidermis, including its associated glands and hairs. The cutis vera was unaffected except, of course, in so far as it lacked hair follicles, sweat and sebaceous glands.

Dr. PERCY LEWIS (Folkestone) showed photographs of a case of Erythema Multiforme in a boy, æt. 8. He considered it produced by a toxæmic condition induced by injudicious feeding.]

HARVEIAN SOCIETY OF LONDON.

A "Clinical Meeting" held January 25th, 1906, at the Stafford Rooms.

Dr. ALEXANDER MORISON showed a case of Endocarditis in a child, associated with chorea.

Dr. GUTHRIE showed a case of probable "gummy Tumour" in the left cerebral hemisphere. The case will be found in another column under the heading of "Clinical Records."

Mr. CAMPBELL WILLIAMS suggested intra-muscular injections of some form of mercury, preferably calomel, as the most suitable treatment.

Dr. SQUIRE showed a case of "Leontiasis Ossea" (?) in a woman, æt. 29. There had been proptosis and deformity of the forehead from birth. The blindness of the right eye was first noticed at the age of nine. Has been gradually losing sight of left eye; can just count fingers. Forehead is large and there is a marked bony protuberance at the site of the anterior fontanelle. The nasal bones are thickened and the septum is deflected.

Dr. LEONARD GUTHRIE suggested that the malformation was a congenital deformity due to premature synostosis of certain cranial sutures, rather than one caused by Leontiasis Ossea. In such cases, the cranial bones, if prevented from growing in one direction by premature ossification of sutures, expanded in another in order to make room for the growing brain. Characteristic malformations to which various names had been given, resulted. Thus, "Scapho-cephalus," or "boat-shaped" skull, narrow and long with projection of frontal and occipital bones and keel-shaped ridge on the vertex, was due to premature synostosis of the sagittal suture.

The name "Spheno-cephalus" (wedge-shaped skull) had been given to such cases as the present in which synostosis of the parieto-occipital and parieto-frontal sutures led to shortened antero-posterior diameter. The frontal bone here was small and retreating, whilst at the site of the anterior fontanelle, a large wedge or dome-shaped promontory had been formed in order to accommodate the brain. The "frog-face" with bulging eyes, ill-shaped nose, narrow, high arched palate, depended upon defective development of the sphenoid from a similar defect in ossification. The optic atrophy might be due to pressure on the optic nerve, but more probably was a primary and early decay in keeping with general mal-development.

Dr. CAUTLEY agreed with Dr. Guthrie that the case was one of "tower-shaped" skull due to congenital malformation.

Mr. CRISP ENGLISH showed a case of abnormal growth of hair on the chest and shoulder in a man. He also showed a case of carcinoma of both breasts in a woman, æt. 54. A depressed scar on right breast had been noticed twelve months, a swelling of left breast for six months. There were some enlarged glands in both axillæ. He raised the question of treatment.

Mr. EDMUND OWEN advised removal of both breasts, but pointed out that the swelling of the arm was of serious prognostic significance as it implied obstruction to lymphatics or pressure on veins by the growth.

Mr. RAYMOND JOHNSON considered that the swelling of the arm probably indicated actual invasion of the veins by the growth.

Mr. LAMING EVANS showed a case of a skin eruption in a boy, which he considered to be an unusual form of Lichen planus.

Mr. CAMPBELL WILLIAMS discussed the case.

Dr. JOHN BROADBENT showed a case of pulmonary stenosis, probably of congenital origin, in a man, æt. 26. There was a loud systolic murmur over the pulmonary cartilage, but no thrill, and no cyanosis or dyspnoea except on exertion.

Dr. ROBERT MAGUIRE held that the defect in such cases was uncertain except in the case of defect of the inter-ventricular septum. The case under discussion was exceptional. The absence of enlargement or undue

pulsation of the right ventricle seemed to negative pulmonary stenosis. He suggested a persistent ductus arteriosus. It was remarkable that an extreme degree of malformation might exist without cyanosis. In one case he had under observation for eight years there was frequently no cyanosis, but at the autopsy there was only one ventricle, the septum being practically absent.

Dr. ALEXANDER MORISON considered that the lesion might be a defect of the inter-ventricular septum.

Dr. CAUTLEY agreed with Dr. Broadbent that the case was probably one of pulmonary stenosis.

THE LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, JANUARY 18TH, 1906.
MR. FRANK T. PAUL, F.R.C.S., President, in the Chair.

A NEW REMEDY FOR DIABETES.

Dr. J. HILL ABRAM read a note on the exhibition of Secretin, the acid extract of duodenal mucous membrane, in cases of diabetes mellitus. Among other cases Dr. Abram related one of well-developed diabetes in a young patient who made an excellent recovery whilst taking secretin.

Prof. WM. CARTER considered Dr. Abram's communication as most hopeful and full of encouraging possibilities in the treatment of a disease, which, when occurring in patients as young as one of his, had always been regarded as fatal. He for one thanked him heartily for having unreservedly placed in our hands his methods.

Dr. F. A. POND related a case occurring in a young girl of nineteen. The patient was in extremis on the eighteenth day, but recovered completely under the exhibition of tr. digitalis and tr. nucis vomicæ, and the administration of sugar.

Prof. Moore, Dr. R. J. M. Buchanan, Dr. Stooka, Dr. E. T. Davies, Dr. Graham-Martin, and Dr. J. T. Williams also spoke.

THE HÆMATOLOGY OF PREGNANCY AND THE PUERPERAL STATE.

Dr. J. C. M. GIVEN read a paper on "The Composition of the Blood in Pregnancy and the Puerperal State." It was based on the investigation of twelve cases of labour in which the blood was examined before and after labour and at stated intervals during the lying-in periods. A marked leucocytosis of the polymorphonuclear type occurs immediately after labour, and rapidly sinks to normal by the end of the first week. A progressive increase in the number of the lymphocytes then occurs, until at the end of the second or third week they are more numerous than the polymorphonuclear cells. The influence of premature labour, stillbirth, albuminuria, &c. on the blood count was noted.

The PRESIDENT expressed his regret that time would not permit of any discussion on Dr. Given's valuable and interesting paper.

THE COMPLICATIONS OF PNEUMONIA AND THEIR TREATMENT.

Dr. NATHAN RAW read a paper on "The Complications of Pneumonia" which he had met with in an observation of 1,832 cases. He referred more especially to empyema, pericarditis, endocarditis, and the acute general infections produced by the pneumococcus, such as septicæmia, meningitis, arthritis, and peritonitis.

Prof. WM. CARTER referred to two conditions in pneumonia not alluded to by Dr. Raw, one at the onset of the disease, where the engorgement was sometimes so general as to threaten life; the patient sat up, the right heart was over-distended, the pulse small, the face pale or livid, and the respiration laboured; in this condition bleeding was followed by speedy relief. The other was the violent delirium which sometimes suddenly followed the crisis. Opium, which would possibly have killed the patient at an earlier stage, would now save his life. Thirdly, Dr. Carter thought that considering the intense coagulability of the exudate

and the fact that it contained a large amount of calcium salts, preparations of this metal should not be administered at any stage of the disease.

Dr. J. HILL ABRAM said that in a healthy subject complications were less often seen than in almost any other infective disease. They were mainly due to previous damage, e.g., pneumococcal endocarditis, implanted upon old valvular trouble. Many complications, too, are due to secondary infections, as in a congenital heart case under his own care, where the infective trouble was proved to be streptococcal in nature. He could not agree that jaundice was often seen in right-sided cases; in the early stages jaundice was the result of toxæmia, and not serious.

Dr. W. B. WARRINGTON remarked that among the complications seen by him were: apical abscess of the lungs, the diagnosis being made by the persistent presence of elastic fibres in the sputum with diplococci and no tubercle bacilli; extensive and confluent hæmorrhages under the skin, the autopsy revealing pneumonia only; gangrene of the lungs and apparently primary pneumococcal meningitis.

Dr. A. G. GULLAN related two cases of pneumonia, in which typical relapses occurred after 24 hours of normal temperature. These relapses both lasted about eight days, terminated by crises and were accompanied by the physical signs of lobar pneumonia in another part of the lungs.

The following gentlemen also took part in the discussion:—Drs R. J. M. Buchanan, Dr. E. E. Glynn, Mr. Stockdale, Dr. E. T. Davies, Dr. J. Lloyd Roberts.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, F.bruary 4th, 1906.
ABDOMINAL NEURALGIA.

THE commonest forms of neuralgia are those of the face, the sciatic and intercostal nerves. Neuralgia can exist in every place where there is a nerve, but certain forms, as those three just mentioned, are observed most frequently. As regards affections of women, says Dr. Leon Archambault, in his work just out, we are often called to treat abdominal neuralgia, closely connected with the complex genital organs of woman. One form may be due to metritis, another to salpingitis, still another to erosion of the os, etc.; they are of reflex origin.

Women are more predisposed than men to neuralgia; there exists also a question of heredity, and certain maladies, as anæmia, intermittent fever, gout, syphilis, predispose to it. And, a remarkable fact, there is frequently disproportion between the effect and the cause; a very insignificant cause may give rise to intolerable neuralgia, while a very grave affection is attended with but little pain.

Neuralgia of the uterus, for instance, is frequently caused by a small lesion, but is so intense that a grave affection is feared by the patient; happily, there is nothing of the sort. Hystericalgia is generally observed in patients of a nervous disposition and especially in those who present signs of hysteria, and even attacks of hysteria have preceded the neuralgic pains. Sometimes the suffering is very intense; at others moderate, and yet, again, the phenomenon consists only in simple pruritis. Walking, dancing, equitation increases the pain, but curious to say the menses have no influence on this form of neuralgia.

Neuralgia of the ovary, like hystericalgia, is observed in nervous and neurasthenic persons, but it is not so painful, it exists only at one side, that of an ovary that had been formerly diseased and in which there still exists a painful cicatrix. Rarely both sides are affected.

Any effort, abdominal palpation, can provoke the pain, and sometimes an attack of hysteria. Neuralgia

of the vulva is often observed, but, strictly speaking, it consists simply in an excessive sensibility of the external genital organs. The slightest contact produces intense suffering, and that in the absence of any lesion. Naturally marriage is impossible to these patients.

Other kinds of neuralgia are the indirect consequence of abdominal affections in women, as intercostal neuralgia, seen so often in cases of metritis and especially in lesions of the os; sciatica, observed in every affection of the pelvis, but more especially in salpingitis, cardialgia or pain at the apex of the heart, accompanies frequently genital affections, as well as neuralgia of the breast, which is frequently very painful.

Gastralgia is very frequent in all women's diseases. All these forms of neuralgia are fortunately easy to relieve, but in some patients they are very tenacious, and of a duration impossible to define, as they belong more to a nervous state of the constitution than to a lesion of an organ.

The treatment of neuralgia in women is that of neuralgia in general, but it requires frequently tact and tenacity. The anti-neuralgic agents are very numerous, but antipyrin might be tried the first.

Antipyrin	2½ drachms.
Tincture of digitalis	1 drachm.
Water	2 ounces.

A teaspoonful every three hours.

Exalgin gives good relief as well as phenacetin, but they should be prescribed with prudence. Five grains of the former, two or three times a day, and from 10 to 30 of the latter, in fractions of 5 grains.

Methylene blue is very active and without danger, but the patient must be told of its effect on the urine.

Methylene blue	1½ grains.
Medicinal soap	q. s.

For one pill. 2 to 10 daily.

Oxycamphor is also a sedative, but acts especially on dyspnoea; it is given in from 15 to 30 grains daily.

Atropine and morphia in subcutaneous injections act well, but there is danger of the patient falling into the morphia habit.

Revulsion over the affected part is of great utility.

Menthol	15 grains.
Sulphide of carbon	1 ounce.

To be painted over the seat of pain.

A blister gives frequently good results, or pulverisations with chloride of methyl. Tincture of iodine or poultices are anodyne methods, but might sometimes be employed.

Certain medicinal agents are unreliable in their action, but have sometimes succeeded where others failed; iodide of potassium, 5 grains twice a day; sulphate of quinine in small doses (5 to 10) grains daily.

For the treatment of sciatica the following injections are recommended:—

Glycerophosphate of lime ..	¾ gr.
" of magnesia ..	"
" of potash ..	"
Water	15 m.m.

For one injection.

The following pills succeed also very well.

Ext. of belladonna	4 grains.
Ext. of stramonium	8 grains.
Lactophenine	1½ drachms.

Divide into 20 pills; 2 to 3 a day.

HÆMORRHOIDS AND FISSURES.

Storain	5 grains.
Sal. of adrenaline (1-1,000) ..	30 m.m.
Lanoline	½ ounce.
Vaseline	½ ounce.

PSORIASIS.

Pyrogallic acid	1 drachm.
Salicylic acid	1 drachm.
Ether and spirit to liquefy ..	"
Elastic collodion	2½ ounces.

Apply with a brush to the patches.

GERMANY.

Berlin, February 4th, 1906.

THE TREATMENT OF DIABETES INSIPIDUS.

DR. C. POSNER has an article in the *Klin. Wochensch.* in which the treatment of this distressing and fatal malady is discussed. He says the treatment can only be etiological when the disease is caused by syphilis, and that even then it not unfrequently fails. The recently recommended strychnine also fails in individual cases. The restricted water cure sometimes gives results that are lasting. This form—the "dry treatment"—is recommended in all cases of primary polydipsia, whilst in cases of primary polyuria it not only does no good, but may do harm.

We are therefore thrown back upon a symptomatic treatment, that of the tormenting thirst and dryness of the mouth. The writer makes use of the chewing tablets (Bergmann's) 5 or 6 a day, which stimulate the secretions of the salivary glands and help to lessen the distressing thirst. This was successful in the case of a woman, æt. 56. On the first and second days of treatment, she secreted 250 to 300 grammes of saliva, the quantity becoming reduced later on. The thirst was better even when the urine still continued above the normal. The specific gravity corresponded to the diminished excretion of urine (from 6,800 to 3,000 cc.m.), and rose from 1004 to 1012. The writer thinks the tablets will prove useful in other forms of polyuria and polydipsia.

THE PRIMARY RESULTS OF ANTICIPATED CLIMAX

In the *Monatsch. für Geburtsh. und Gynäkol.*, an article appears on this subject by Dr. Emil Pollok, and is a discussion of the subject from an experimental side. After castrating a number of female rabbits the animals were killed and the parts subjected to examination eleven months afterwards. He found the mucous membrane of the tubes partly swollen and corresponding to a commencing carvolyolysis; fatty cells were present in the protoplasm. Ciliated epithelium, which is normally present in the tubal epithelium of German rabbits was no longer so. The degenerative changes also affected the muscular coats of the tubes. Castration set up distinct changes in the uterus itself, which consisted in swelling, deposition of fatty granules, and disappearance of the utricular glands. The further action of castration consists in a fatty inundation of the parenchymatous organs in which, in an especial manner the musculature of the heart suffered. The fatty infiltration of the muscles of the heart perhaps had some connection with the climacteric symptoms that women suffer from in anticipated climax.

Paul Rosenstein discusses the

TRACT OF INFECTION IN THE FEMALE GENITAL ORGANS.

Isolated tubercle of the ovary was not proved, it was associated with tubercle of the peritoneum and Fallopiian tubes. In the latter the descending form was the most frequent—the next frequent form was through the blood vessels, whilst the ascending form was only rarely observed with certainty. Tuberculosis of the tubes appeared to be always bilateral and to be located in the first instance in the mucosa. Tubercle of the tubes as well as of the ovary led quickly to regressive changes—to cariation. The adenoma-like growth on the isthmus of the tubes was not necessarily tuberculous. The characteristic histological changes were sufficient proof of their tuberculous character without any staining of tubercle bacilli.

AUSTRIA.

Vienna, Feb. 4th, 1906.

LEPROSY.

Neumann gave the history and showed a patient he presented to the "Gesellschaft" in 1900, suffering from leprosy. The patient is an officer from Bulgaria, æt. 45, who had suffered from *Leprosy-maculo-tuberosa* five years before he presented himself to Neumann. The forehead was dark brown, the eyebrows, lids and cheeks, greatly swollen, and the body covered with numerous brown patches. On the abdomen and legs hard swellings varying from the size of peas to that of large beans, sharply defined, and dark-coloured. In the sputum, nasal secretions, and parts excised from

the skin, the lepra bacilli were found in large quantities.

The treatment comprised injections of Chaulmoogra oil, *solutio Fowleri* combined with the iodide of potassium.

The patient now seems perfectly free from every symptom of the disease, and is in excellent health!

SPINA BIFIDA OCCULTA.

Frisch showed a patient with accentuated lordosis, slight sclerosis, elevated scapula, and waving gait, as if he suffered from congenital luxation of the hip joint, while the head of the femur was found to roll naturally in the acetabulum.

Over the site of the second lumbar vertebra a deep hole could be found, hard and bony at the bottom, from which a serous fluid exuded on both sides. The Röntgen rays revealed a separation of the cord into two portions.

PERINEXITIS OF BLADDER.

Exner showed a patient he had operated on for perivascular inflammation of the bladder.

The patient was fifty-four years of age, and took ill about a year and a half ago, with severe pain on micturition and cloudiness of urine.

The attendant discovered a small swelling in vesicle region at the time, which as suddenly disappeared. The patient remained thereafter two months perfectly free from pain, but was again visited with all the symptoms of cystitis. The cystoscope was applied, and a small tumour about the size of a marble was found projecting from the inside wall of the organ.

The operation of *sectio-alta* was performed, and the top of the bladder found to be firmly embedded in peritoneum, in which was entangled the omentum and part of the small intestine.

After the adhesions were removed the peritoneum was found penetrating the wall of the bladder, which formed the tumour on the inside. The morbid part of the bladder was resected, the organ closed with sutures, and the patient recovered without any untoward symptoms.

The subsequent examination of the tumour disappointed the presumption first formed of the growth being a malignant neoplasm.

It proved to be a splinter of wood embedded in a mass of granulation tissue, but how the foreign body reached this inaccessible region no evidence is forthcoming. The presumption is that the wood was swallowed in the food and subsequently passed through the wall of the small intestine, carrying the inflammatory peritoneum with it into the wall of the bladder.

Kapsamer recorded a similar case in a female, æt. 40, who came to him with all the symptoms of cystitis. On examining with the cystoscope an inflammatory tumour was discovered on the right side of the bladder as an incrustation. The *sectio-alta* revealed a long phosphatic stone 3 centimetres in length, embedded in the shaggy papilla of the mucous membrane and covered with the product of cystitis proliferans. This supposed stone turned out to be an incrustated bone of a fowl. The patient was dismissed from hospital perfectly cured.

A year later she returned with severe pain in the bladder and pyuria. The cystoscope revealed a tumour on the same place as before, but on this occasion it had a more necrotic appearance. *Sectio-alta* was again performed and an incrustated tumour of fæces about the size of a pigeon's egg removed. After removing the stone the index finger could be passed into a channel running along the wall of the bladder, to an opening in the bowel, where an abscess had been created. The wound was finally closed, but the inflamed mucous membrane of the bladder never seemed to heal, but took a sort of œdema bullosum from which she died some time after.

The *post-mortem* added no more to our knowledge in the case. No history of a trouble with the bowel or alimentary canal was complained of during life, nor anything in the abdomen that would lead one to suspect injury or alteration in the alimentary canal. All the symptoms pointed to the bladder from beginning to end.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

GLASGOW ROYAL INFIRMARY AND ST. MUNGO'S COLLEGE.—At the annual meeting of contributors, held on January 29th, Dr. D. C. McVail moved an amendment to the report of the Infirmary in the following terms: "That as the annual report contains no information regarding St. Mungo's College, the medical school of the Infirmary, which was founded by the Infirmary, and as important questions have arisen vitally affecting the status and future of the College and in particular the question of affiliation to the University, and, further, as an important representation by the Governors of the College has been made to the managers of the Infirmary to which no answer has yet been sent, this meeting, so far as regards the approval of this report, do stand adjourned to this day month, in order that full information on these matters may be laid before the qualified contributors, and such action taken thereupon as may by them be deemed proper." In speaking to his amendment Dr. McVail said that he was the mouthpiece of St. Mungo's College, and that if the reply of the managers to the memorial of the College Governors was unfavourable, the Governors would not continue the College, which had no longer any reason for its existence except to get affiliated to the University in terms of the Act of 1889. The clauses in the Act regulating affiliation had been inserted at the desire of the Infirmary managers who had been the originators of the College. It was the opinion of the Governors that unless their dispute with the Infirmary was settled, affiliation could not be obtained. The amendment was opposed by Mr. J. D. Hedderwick, Chairman of the Managers of the Infirmary, who said that while it was hopeless to discuss the whole of the subjects which interested the managers and the Governors of the College, it was easy to state in a word the fundamental point of disagreement between them. Up till 1883 the term of office of the staff of the Infirmary was 15 years; it was then decided, for various reasons, to reduce this to 10 years, with a possible extension of 5 years in special cases. Then St. Mungo's College came into existence, and the Professors held appointments as members of the staff of the Infirmary; in every case where the 10 years' period terminated in the case of a Professor the 5 years extension was granted, while in the case of other members of the visiting staff who were not Professors, at the end of 10 years they were allowed to go. This discrimination among members of one staff led to dissatisfaction, and in 1898 the managers passed a resolution that staff appointments should be retained until the holders reached the age of 60. In 1905 it happened that three of the members of the staff had been compelled to retire through the operation of this rule, and it was this that had brought about the difference between the College and the Infirmary. He did not believe that the life of St. Mungo's College was threatened because three of its Professors were compelled to resign. To agree to the memorial of the College would be to perpetuate what had been found in other hospitals a misfortune—namely, the indefinite retention of office by certain members of the staff. After some further remarks, it was agreed that the amendment should be withdrawn on the understanding that failing a private arrangement between the parties the matter should again be brought up in public. The question of an age limit is always a vexed one in hospitals, and it is a matter in which it is very difficult to introduce reform without trampling on some vested interest or supposed vested interest. Desirable as a retiring limit is, it is undoubtedly unfortunate for St. Mungo's College, on the eve of affiliation, to be compelled to "swap horses," and possibly some *modus vivendi* will be arranged which will permit of the retention of office of the old teachers until the period of transition is safely over.

SMALL-POX IN SCOTLAND.—On the morning of the 29th, on the arrival at Dundee of the ss. *Pindari*, a

somewhat serious outbreak of small-pox was discovered on board the vessel. She left Calcutta in December, and while in the Red Sea small-pox broke out among the Lascar crew, which subsequently also attacked eight of the British officers. Dr. Templeman at once boarded the vessel, and had the patients conveyed by a special tug to hospital.

ELECTION OF DIRECT REPRESENTATIVES FOR SCOTLAND.—Dr. Bruce, Dingwall, contradicts the rumour that he is not going to seek election as direct representative at the Election next October.

BELFAST.

FORSTER GREEN HOSPITAL FOR CONSUMPTION.—The tenth annual meeting of this hospital was held in Belfast last week, when an interesting medical report was read by Dr. Howard Sinclair, the honorary secretary of the medical staff. The extern department, which is carried on in the city, is practically a selecting ground for cases to be treated in the hospital, the latter being conducted as an open-air sanatorium. During the past year 525 new cases were seen in the extern department, and 180 patients were treated in the hospital, the average number of beds occupied being 33. Dr. Sinclair referred to the recent researches of Professor Behring, and to the discoveries of our old fellow-townsmen Dr. Almroth Wright concerning the resisting powers of the blood. An interesting point about Dr. Wright's investigations is the way in which they confirm from the scientific side what we so firmly believe on clinical grounds, the great value of open-air treatment.

NEWTOWNARDS NURSING SOCIETY.—At the annual meeting of this society, which was held last week, the chair was taken by the Marchioness of Londonderry, who gave a long address on the work in which she is so deeply interested. There were some nine or ten speakers at the meeting, but no medical man is mentioned among them, or even among those present. It is a matter of great regret that the medical men of towns and districts where such nursing societies exist do not keep more closely in touch with the management of them. No doubt cases occur where the nurse seems to interfere with the proper work of the medical attendant, but such cases often occur through ignorance, and the influence of medical men on the committees of management is the best preventive of trouble.

ELECTION OF DIRECT REPRESENTATIVE.—As far as can be judged from conversation Dr. Kidd obtained in the recent election a large measure of support in Belfast and its neighbourhood. So far back as last spring the members of the Ulster Medical Society agreed by a large majority to support his candidature, not from any special objection to Sir William Thompson, but on the ground that it was unfair that all the Irish members of the General Medical Council should be Dublin men. Sir William Thompson had, however, a number of personal friends in the north, who remain faithful to him. On the whole the election has attracted exceedingly little interest, probably because we are surfeited with elections and election literature at present.

PUBLIC HEALTH.—In the five weeks ending January 20th, the cases reported under the Notification Act in Belfast were as follows:—131 scarlatina, 99 typhoid, 55 simple continued fever, 46 erysipelas, 21 diphtheria, 6 typhus, 2 membranous croup, and 1 puerperal fever. Of the six cases of typhus five occurred in one house. The deaths from zymotic diseases were 39, from phthisis and diseases of the respiratory system, 192, as against 103 and 271 in the corresponding period last year. The death rate from all causes was 19.9. The question of the contamination of the Belfast water supply by the discharge of sewage into the Stoneyford Reservoir, was discussed at the last meeting of the Corporation, but the only satisfaction which could be got from the chairman of the Public Health Committee was that the matter was being inquired into, an answer which has been given in various forms for several years. Meantime typhoid shows distinct signs of increasing.

MEDICAL NEWS IN BRIEF.

An Alleged Bogus Doctor.—Serious Charge at Southam.

At Southam, John Dale Tucker, alias William Edward Tucker, alias Dr. William Eldon Tucker, was charged by the Director of Public Prosecutions "for that he did feloniously give a false certificate, and that he did utter the said certificate knowing it to be forged." The evidence was to the effect that the executors of the late Dr. Roper advertised the practice at Napton for sale, and prisoner, writing in the name of W. E. Tucker, replied. By arrangement with one of the executors, prisoner went to Napton and represented himself as Dr. William Eldon Tucker, of Bermuda, which place he said he had to leave because he was consuming two bottles of brandy a day. He was engaged temporarily as *locum tenens*, at four guineas a week, and agreed to purchase the practice for £150, in monthly instalments of £5. Only two instalments had been paid, and before the second sum was received it was ascertained that prisoner was negotiating for the sale of the practice to Dr. Croby for £170, a thing he had no right to do. Witnesses spoke to prisoner giving certificates of death, signed W. E. Tucker.—Dr. Henry Robinson, of London, said he was well acquainted with Dr. William Eldon Tucker, who was in a settled practice in Bermuda. Prisoner was not the man. Police-Constable Isaac Hetherington said in 1904 prisoner lived at 101, Everton Road, Liverpool, and was practising as an unqualified practitioner under the name of Dr. Henry Gould. Subsequently witness came to know him as John Dale Tucker.—Dr. Henry Croby, M.D., said he agreed to purchase the practice for £170. He drew a cheque, payable to William Eldon Tucker, M.B. The prisoner was committed for trial at the next Warwick Assizes, and was offered bail: himself, in £200 and two sureties in £200 each.

Lead Poisoning.—Dangerous Manufactory in East End of London.

THE manufacture of electric accumulators has been scheduled by the Home Office as a dangerous trade, and at the Thames Court, the London Electrical Syndicate, Ltd., of Abbott's Road, Poplar, were summoned for having their works in such a condition that the manufacture of the accumulators could not be carried on without danger to health. Dr. T. Morrison Legge, Medical Inspector of Factories, visited the workshop on Jan. 23rd, and found that the regulations had not been complied with. The mixing of red lead and litharge paste had been carried on without an exhaust fan to carry away the dust. Witness found a workman who had suffered from lead poisoning. In addition to the fan, the bench at which the mixing was done should be covered with sheet lead and the floor concreted, so as to be capable of being washed down every day. The Magistrate made an order that the manufacture should not be carried on until the improvements had been effected, and allowed 25s. costs.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held at 429, Strand, London, W.C., on 26th ult. There were present Dr. A. Havilland Hall in the chair; Mr. H. P. Symonds (Oxford), Dr. J. Brindley James, Dr. Frederick S. Palmer, Dr. M. Greenwood, Mr. Edward Bartlett, Mr. F. S. Edwards, Dr. F. J. Allan, Mr. J. F. Colyer, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The records of the business for the month of December were very satisfactory and enabled the committee to form an estimate of the result of the working of the society for the year 1905. It was found that the heavy sickness pay disbursement experienced in the spring had been more than balanced by the small

claim account of the summer and autumn and the net result of the years' working is a substantial addition to the financial reserves of the Society. The working expenses have been, as usual, less than half the amount allowed by the rules, and the number of new entrants greater than in any previous year. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Royal College of Physicians of Ireland.—Presentation to the Registrar.

AN interesting ceremony took place at the usual monthly meeting of the College on Friday last, when the President, Sir William Smyly made a presentation in the name of the Fellows to Dr. James Craig, Registrar to the College, on the occasion of his approaching marriage. The presentation took the form of a handsome cabinet of table silver and cutlery, to which was added an album containing the signatures of the Fellows. Dr. Craig has acted as Registrar now for nearly twelve years, and has endeared himself to the Fellows by the manner in which he has discharged his many duties. In addition to his official connection with the College he possesses many other interests in the medical world in Dublin, and as General Secretary is responsible to a large degree for the management of the Royal Academy of Medicine in Ireland. His many friends in the medical profession will welcome the very fitting compliment which has been paid him by his College.

Medical Appointments in Viceregal Household.

HIS Excellency the Lord Lieutenant has been pleased to make the following appointments to the Viceregal Household:—Physicians in Ordinary—Sir Christopher Nixon, M.D., William John Thompson, Esquire, M.D. Surgeons in Ordinary—R. F. Tobin, Esq., F.R.C.S.I., Sir Arthur Chance, President R.C.S.I. Surgeon to Household—John Lentaing, Esq., F.R.C.S.I. Surgeon Oculist in Ordinary—Frank C. Crawley, Esq., M.D., F.R.C.S.I. Surgeon Dentist in Ordinary—Kevin E. O'Duffy, Esq., L.D.S.

Indian Medical Service.

DURING the competitive examinations for Commissions in the Indian Medical Service, held in January, forty-four candidates presented themselves for twenty-three vacancies. The following is a list of the successful candidates arranged according to merit:—

Harry Pierpoint, Liverpool Univ., F.R.C.S.Eng., L.R.C.P.; William David Henderson Stevenson, Glasgow Univ., M.B., Ch.B.Glasg.; Henry Puttullo Cook, Edinburgh Univ., M.B., Ch.B.Edin.; Percy Strickland Mills, Guy's Hosp., M.B., B.S.Lond., M.R.C.S., L.R.C.P.; Khandu Gaupatrao Gharpurey, Edin. Univ., L.R.C.P. and S.Edin., L.F.P. and S.Glasg.; William James Fraser, Edinburgh Univ., M.B., Ch.B. Edin.; Desmond Charles Villiers FitzGerald, Dublin, L.R.C.P. and S.Ireland.; Charles Richard O'Brien, Edinburgh Univ., M.B., Ch.B.Edin.; Robert Siggins Kennedy, Queen's College, Cork, M.B., B.Ch. Royal Univ., Ireland.; Charles Aubrey Godson, St. George's Hosp., M.R.C.S., L.R.C.P.; Bernard Higham, St. Thomas's Hosp., M.R.C.S., L.R.C.P.; Norman Haliburton Hume, Durham Univ. and London Hosp., M.B., B.S.Durh., M.R.C.S., L.R.C.P.; Reginald Henry Lee, Trinity College, Dublin, M.B., B.Ch.Dub.; Greer Edmund Malcomson, Guy's Hosp., M.D.Lond.; Frank Phillips Wernicke, Edinburgh Univ., M.B., Ch.B.Edin.; Patrick Heffernan, Trinity College, Dublin, M.B., B.Ch., B.A.Royal Univ., Ireland; William Anderson Mearns, Aberdeen Univ., M.A., M.B., Ch.B.Aberd.; Duncan Macdonald C. Church, Edinburgh Univ.; M.D., Ch.B.Edin.; Stanley Trefusis Crump, Leeds Univ., M.R.C.S., L.R.C.P.; Harry Stewart Hutchison, Glasgow Univ., M.B., Ch.B., B.Sc.Glasg.; Robert George Gibbon Croly, Queen's

College, Cork, M.B., B.Ch. Royal Univ., Ireland; William Barbour Alexander K. Cullen, Edinburgh Univ., M.B., Ch.B. Edin.; James MacGregor Skinner, Owens College, Manchester, M.B., Ch.V. Vict.

Army Medical Service.

List of successful candidates at the recent Competitive Examination for the Royal Army Medical Corps, arranged in order of merit:—

Charles M. Drew, M.A., M.B., Ch.B. Glasg.; Archibald A. Sutcliff, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond.; Arthur G. Cummins, M.B., B.Ch., R.U.I.; Alfred S. Millard, M.B., B.Ch., B.Sc. Edin.; Hugh E. Gotelee, M.R.C.S. Eng., L.R.C.P. Lond.; Archibald S. Littlejohns, M.R.C.S. Eng., B.A. Cantab.; Frank A. McCammon, M.B., B.Ch., R.U.I.; William R. Galwey, M.B., B.Ch., B.A. Dub.; Robert G. Archibald, M.B., B.Ch. Edin.; George de la Cour, M.R.C.S. Eng., L.R.C.P. Lond.; William Egan, M.B., B.Ch., R.U.I.; Frank Forrest, M.R.C.S. Eng., L.R.C.P. Lond.; Timothy W. O. Sexton, M.R.C.S. Eng., L.R.C.P. Lond.; Robert G. H. Tate, M.D., B.Ch., D.P.H., B.A. Dub.; Augustus S. Williams, M.R.C.S. Eng., L.R.C.P. Lond.; Alexander Dawson, M.B., B.Ch. Aberd.; Clive T. Edmunds, M.R.C.S. Eng., L.R.C.P. Lond.; Valentine G. Johnson, M.R.C.S. Eng., L.R.C.P. Lond.; Ernest W. M. Paine, M.R.C.S. Eng., L.R.C.P. Lond.; Edward J. Porteous, M.B., B.Ch. Edin.; Edward M. O'Neill, M.B., B.Ch., R.U.I.; Victor C. Honeybourne, M.R.C.S. Eng., B.A. Cantab.; James C. L. Hingston, M.R.C.S. Eng., L.R.C.P. Lond.; George B. Edwards, M.R.C.S. Eng., L.R.C.P. Lond.; Frederick D. G. Howell, M.R.C.S. Eng., L.R.C.P. Lond.; Charles R. M. Morris, M.B., B.Ch. Dub. Patrick Sampson, L.R.C.P. & S.I.; William H. Gillatt, M.B., B.Ch. Glasg.; John W. L. Scott, M.R.C.S. Eng., L.R.C.P. Lond.; William C. Smales, M.R.C.S. Eng., L.R.C.P. Lond.; John B. G. Mulligan, L.R.C.P. & S. Edin., L.F.P. & S. Glasg.; Arthur H. Bond, M.R.C.S. Eng., L.R.C.P. Lond.; Marcus G. Hill, M.B., B.Ch. Ed.; Richard E. U. Newman, M.B., B.Ch. Edin.; Harold Jacques, L.S.A. Lond.; Donald de Courcy O'Grady, L.R.C.P. & S.I.; Thomas T. H. Robinson, M.B., B.Ch. Dub.; Thomas C. C. Leslie, L.R.C.P. & S.I.; Lawrence G. Gibson, M.R.C.S. Eng., L.R.C.P. Lond.; Philip S. Stewart, M.B., B.Ch. Dub.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on January 29th, with the following results:—

Second Examination (five years' course).—Of twenty-seven candidates entered the following seventeen passed the examination: John McKelvey, Belfast; Peter Morrison Tolmie, Inverness; Hubert Wybrant Powell, Cork; Ormonde Rashleigh Belcher, Cork; Augustus Yourdain Kelsey, Mauritius; Alfred Benjamin Bateman, Cork; James Morham, Edinburgh; Secossene Piarroux Mauritius; Andrew Downie Macfie, Greenock; Thomas Mohan, Louth; Khorshed Sorabji Kanga, Bombay; Edward John Lumsden, Co. Wexford; Charles Austin Paterson, Brazil; Charles James Fail, Edinburgh; George Walter Rundle, Sydney; Llewellyn Etter Davies, Southport; and Hugh Sharpe Williams Roberts, Wales; and one passed in Anatomy.

Third Examination (five years' course).—Of twenty-nine candidates entered the following nineteen passed the examination: Effie Jemima Cassels, Glasgow; Louis Joseph Patterson-Clavier, West Indies; Timothy John Vaughan, Co. Cork; Charles Nyhan, Co. Cork; Richard Baring Davidson, Congleton; Thomas Richard McKenna, Brisbane; James Scott Jackson Stenhouse, New Zealand; Robert Mathia Jones, Holywell (with distinction); William James Valentine Curtain, Melbourne (with distinction); Vincent Sylvester Delany, Longford; John Alfred Steele Phillips, Bengal; Hugh Ferguson Watson, Lochwinnoch; Harry Stokes, India; Lawrence Albuquerque, India; Lakshmiapati, India; Maneckji Burjorji Patel, Bombay; David Williamson, Anderson, South Queensferry; Kaikhusru

Sorabshah Commissariatwalla, Bombay; and Fred Yates, Burnley; and one passed in Pathology and one in Materia Medica.

Final Examination.—Of sixty-two candidates entered the following twenty-five passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.G.: John Galloway, Co. Durham; William Fleming, Durham; Joseph Foreman Berry, Wigan; William Cooke Renshaw, Altrincham; Bernard William Dakers, Hawick; Robert James Manion, Ontario; Syed Imtiaz Hasan, India; John Theodore Anderson, Victoria; Ivan William MacKinnon, Charlottetown; William George Hugh Brooks, Karachi; Oscar Nargolese, Heidelberg; William John Barber, Ontario; Krishnaji Waman Dani, Poona; Clarence William Field, Ontario; George Waller Meade, Cork; Nena Beatrice Ievers, Ceylon; Isaac Harris, Sunderland; William Wilton Johns, Carmarthen; Walter Emory Davies, Wisconsin; Charles Francis, Ceylon; Gilbert Heathcote, Derbyshire; Malcolm Claud Russell Grahame, South India; Robert Carswell, Dalbeattie; John Arthur Cullum, Canada, and George Hart, Glasgow; and eight passed in Medicine and Therapeutics, seven in Midwifery, and ten in Medical Jurisprudence.

NEW PREPARATIONS.

FORMAWN.

THE object of this somewhat novel departure is to treat catarrhs and other abnormal conditions of the nasal mucous membranes with medicated vapour. The special features of the Formawn apparatus may thus be summarised. There is a convenient little inhaler with a double nose-piece and the inhalant is available in the form of a tablet. Nothing could be simpler and handier than the apparatus, which can be carried about from place to place by persons subject to nasal catarrhs. Perhaps one of the most valuable points about the whole thing is the fact that the remedy may be used not only as a curative but also as a preventive for coryza. Medical men wishing to try Formawn can be supplied with samples and literature on application to the Chemical Works, 26, Southwark Bridge Road, London, S.E.

OBITUARY.

SMART ATKINSON FOTHERGILL, L.R.C.P. Ed., M.R.C.S. Eng.

THE death is announced at Haswell of Dr. Smart Atkinson Fothergill. The deceased, who was sixty-eight years of age, had been ill for only about a fortnight. Dr. Fothergill was L.R.C.P. (Edinburgh), and L.M., 1871; and M.R.C.S. (England), 1861. He was public vaccinator in the Haswell and Shotton districts of the Easington Union, surgeon to various local bodies, and a member of the Northumberland and Durham Medical Society. He leaves a widow and grown up family.

GEORGE WELLER, M.R.C.S., L.S.A.

MR. GEORGE WELLER, who practised for many years as a surgeon at Wanstead, died on Thursday at his residence, Russell Lodge, South Croydon, at the age of sixty-five. Mr. Weller received his professional education at the medical school of the London Hospital, where he filled the offices of assistant medical officer, resident obstetric officer, and house surgeon and thence he qualified as M.R.C.S. of the English College, in 1863. While practising at Wanstead he was medical officer to the Royal Merchant Seamen's Orphan Asylum, Snaresbrook, surgeon to the J Division of Police, and surgeon accoucheur to the Wanstead Maternity Society. He had contributed various papers to the professional journals.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Clinical Remarks on Pelvic Appendicitis. — Armstrong, of Montreal (*Brit. Med. Journ.*, Jan. 13th, 1906) reports six cases of pelvic appendicitis, which bear such a close resemblance to each other clinically that he considers they form a fairly distinctive group. There is usually in these cases a sudden onset of pain, which is often more generalised than in the typical form of the disease. Temperature and pulse rate are only moderately increased. Tenderness on pressure is not marked, except on deep pressure over the pelvic region. The diagnosis at the outset is probably appendicitis, but the attendant does not feel certain about it. In twenty-four to forty-eight hours the symptoms improve, and the diagnosis becomes still more uncertain. Then quite suddenly, after two days of apparently normal convalescence, a sharp recrudescence occurs, peritonitis develops, and the condition of the patient soon becomes alarming. In operating on three cases in which the pelvic peritoneum is primarily involved, the Trendelenburg position is of great value, as it renders manipulation more easy, and ensures greater efficiency in cleansing the infected area. Drainage is always necessary—very occasionally in a dependent position, as through the vagina. Convalescence is usually slow. The author's special plea is that a routine rectal and bimanual examination, by fully establishing an uncertain diagnosis, would suggest earlier operative treatment, and lower the death rate in this variety of appendicitis. S.

Carcinoma of the Breast and its Spread into the Lymphatics. — Lockwood (*Brit. Med. Journ.*, Jan. 27th, 1906) considers that when cancer attacks a structure like the mammary gland, which has no capsule, there is hardly any interval of time between the onset of the growth and its spread into the lymphatics. As it is the author's habit to make an immediate microscopic examination of suspicious tumours of the breast, he has often operated on the disease in an unusually early stage. For instance, a female had a small indurated ulcer of the nipple resembling a Hunterian sore. Before operation no glands were felt. When the whole mammary gland, and both pectorals were removed, several enlarged lymphatic glands were found, the largest one highest up and adherent to the upper part of the axillary artery. In some early cases the lymphatics were larger than the growths from which they sprang. Frequently under the microscope the largest glands do not show cancerous structure, while those that are smaller may do so. Enlarged glands may also prove to be tubercular. In Lockwood's experience it is a dangerous delusion to consider duct cancer as less malignant than the other varieties found in the breast. As to the order in which the lymphatic glands will be affected, it is undesirable to have too definite preconceived ideas as to the direction the disease will take. Cancerous growths occasionally extend from one breast to the other, which is contrary to our earliest notions of the scanty anastomosis of vessels across the middle line. The lymphatic on the inner side of the breast may carry carcinoma into the mediastinal glands, and through the epigastric angle into the abdomen. It is always advisable to remove the lymphatic bearing fascia which lies over the junction of the great pectoral muscle and the aponeurosis of the rectus. As regards the axillary invasion, cancer usually spreads to the glands as follows:—Firstly, the glands along the lower border of the pectoralis major are affected, then those about the uppermost part of the axillary vein, and onward to the subclavian. Subsequently the glands about the subscapular, the lower end of the axillary and upper end of the brachial vessels become involved. But the

upper axillary glands may be enlarged though those under the pectorals may have escaped. Deceptive intervals may also intervene between groups of cancerous glands. Disease spreading to the glands in the cervical region is a late complication, but the condition is not a contra-indication to operative procedure. After a flap of skin is turned off the triangles of the neck, a very searching dissection can be made. Moreover, the process of repair in the neck is rapid, and attended with little pain and constitutional complications. S.

Spindle-Shaped Enlargement of the Blind Spot Associated with Congestion of Optic Disc. — Drs. Ramsay and Sutherland (*Oph. Review*, Jan. 1906) in the course of some perimetric observations in cases of sympathetic irritation were enabled to demonstrate by using Bjerrum's screen that Mariotte's blind spot underwent a change in form and size. They describe the normal blind spot as an oblong space with rounded corners lying to the right or left of the fixation point and having a proportion of 6 to 4 in the vertical length and horizontal breadth and as having one third of the space above horizontal level of the fixation point. They then record five cases of sympathetic irritation in which the blind spot of the sympathising eye was lengthened out into a vertical spindle with a proportion between the length and breadth varying from 10 to 4 to 18 to 4. In all five cases there was congestion of the optic disc with more or less lowering of vision. After enucleation of the exciting eye the congestion of the papilla disappeared and vision improved and the blind spot assumed a normal size and shape. Drs. Ramsay and Sutherland consider that this change in the blind spot affords a useful danger signal. In four of the cases reported part of the visual failure was due to transitory myopia of -0.75 to 0.5 D. M.

Amaurosis following the Injection of Paraffin. — Rohmer (*Annales d'oculistique*, Sept., 1905) records the case of a woman who had suffered from syphilitic necrosis of the nasal bones which produced the usual deformity. A medical man made five or six injections of paraffin with intervals of five to six weeks. The last injection was accompanied by pain in the left eye and immediate loss of sight. The pain which lasted some days, caused the woman to lose consciousness. It was not until a year after the accident that Rohmer met the case and then found in the left fundus very large flame-shaped hæmorrhages and areas of choroiditis disseminata. Vision=0. The author considers that the blindness of her eye was due to thrombosis of the retinal veins. As to the technique of the injections, Rohmer thinks that no more than 3 grammes of paraffin (41° to 42° C.) should be injected slowly with a Lürer's syringe, and the area affected should be controlled by pressure of the fingers. Rohmer refers to such another case which occurred in Nancy. Four or five cases of a similar accident have been recorded within the past few years. M.

Hæmorrhages in the Eye present at Birth. — Dr. Coburn (*Arch. of Ophthalmology*, May, 1904) examined the eyes of 37 infants who were still born, or who had lived for varying periods up to 22 days. He found hæmorrhages in various parts of the eye in 17 cases (21.5 per cent.). The results of other investigators gave a frequency of 10 to 41 per cent., some relying on the ophthalmoscope and others on the microscope for their information as to the presence of hæmorrhages. Coburn found the hæmorrhages in all the tissues behind the ciliary body except the choroid. Retinal hæmorrhages were present in all of the 17 cases. Although in the vast majority of cases in

which this form of accident has occurred there are no after effects to be recognised in adult life, yet, it may be supposed that some of the cases of amblyopia and strabismus, chorioidal atrophy, retinal changes or even glioma have had their origin in hæmorrhages at the time of birth. The author considers the hæmorrhages to be due to the disturbance of the retinal circulation, resulting from compression of the optic nerve and its central blood vessels, due to a distention of the optic nerve sheath with cerebro-spinal fluid from compression of the head occurring during labour. M.

A Note on the Condition of Patients after the Removal of the Appendix.—Lawrence Jones (*Lancet*, Dec., 1905) inquired into the present condition of patients who had been operated on in St. George's Hospital during the three previous years. Of these he was able to trace 87; information was specially asked for on the following points:—(1) the existence of pain, constipation, flatulence, &c., as being possibly caused by adhesions; (2) tenderness of the scar; (3) ventral hernia. Of the 87 patients, 54 had been in perfect health since their discharge from hospital, 27 have enjoyed good health, but have symptoms which from time to time call their attention to the scar; six have definite grounds for complaint of bad health since the operation, three having ventral hernias, three having pain. The author again divides these 87 cases into 44 in which there was drainage employed, and 43 in which the wounds were closed, of the former 19 have had after troubles, of the latter only 14. 13 patients in all have had bulging of the scar or actual hernia. Of these 9 belong to the group whose wounds were drained, only 4 to those whose wounds were closed. In 17 cases where an abscess had formed the appendix was not removed, two of these cases had subsequent acute attacks of appendicitis. Mr. Jones believes that bad after results are far less common among patients whose appendices are removed early in an acute attack, especially if it is the first attack, than where the case is allowed to go on to suppuration or to the formation of adhesions consequent to the recurrence of the disease. G.

The Vicious Circle after Gastro-enterostomy.—In a paper on this subject John Deaver (*New York Med. Journ.*, Dec., 1905) applies the term "vicious circle" to all those cases in which patients suffer from persistent vomiting after the operation of gastro-enterostomy. He points out the fact that while we do not know the real cause of the vicious circle yet we have learned empirically that the posterior anastomosis, with a portion of the jejunum as short as it can conveniently be made, is the form of operation of all others least likely to be followed by pernicious vomiting. By performing this operation, which Mr. Deaver believes to be the correct one, troublesome vomiting will in the large majority of cases be prevented, but should it occur, then no time must be lost in re-opening the abdomen, when in all probability an entero-anastomosis will be the best treatment. Should this fail, then the pylorus should be ligatured with strong silk, and in this way the contents of the stomach prevented from entering the over-distended duodenum. If this second attempt fails, then ligation of the proximal loop should be tried as a last resort. G.

Post-Operative Vomiting and Nausea.—L. Holmes (*Amer. Med.*, Dec., 1905) draws the following conclusions from a careful study of 100 cases:—(1) As a rule, post-operative nausea and vomiting are less dependent on the anæsthetic used than on other causes. Of the pre-disposing causes, sex seems to be the most important, women suffering more than men. (2) The amount of post operative disturbance bears a more or less definite relation to the nature of the operation, those performed on the female genital organs being the worst; abdominal operations coming second, and least upsetting of all, operations in which neither the female genital organs nor the abdomen are interfered with. (3) Vomiting after chloroform is as bad or worse than that which follows the administration of ether. (4) The proper preparation of the patient before operation and the correct treatment after operation

are most important, everything should be kept out of the stomach for at least 12 hours and if possible for 24 hours after an anæsthetic. (5) The degree of gastric disturbance following etherisation has no relation whatever to the amount of ether used. G.

Axillary and Pectoral Cicatrices following Removal of the Breast.—John B. Murphy (*New York Med. Journ.*, Dec., 1905) classifies undesirable sequelæ following mammary amputations and axillary dissections into the five following classes:—(1) fixation of the arm to the chest with more or less limitation of movement. (2) Venous stasis in the arm and forearm with œdema. (3) Lymph œdema of the arm and forearm. (4) Neuralgia in the arm and forearm. (5) Sensitive retracting scars. He gives the causes of these sequelæ as (a) line and position of the incision; (b) excision of skin; (c) leaving arteries, veins, and nerves in the excavated axilla without a muscular or aponeurotic covering; (d) malposition of the arm immediately after operation; (e) allowing too great a dead space to exist between the apex and the base of the axillary triangle during the process of repair; (f) an absence of accurate contact of all the wound surfaces in the axilla immediately after operation; (g) recurrence of carcinoma in the axilla or the sub-clavicular space. The worst results follow when the incision is made along the margin of the pectoralis muscle, as the contracting scar draws the arm closer and closer to the side. The best results are obtained by making the incision high up on the chest and rectangular, the apex just beneath the acromion, the inner limit parallel to the fibres of the pectoral, the outer parallel to the long axis of the humerus. The exposed axillary vessels and nerves must be covered by taking a flap of muscle from the outer edge of the pectoralis major or from the latissimus dorsi, and fixing this in to the apex of the axilla, in this way forming a good covering for the vessels and nerves. The arm is held at right angles to the body by means of a plaster of Paris casing, which is removed on tenth day, leaving the arm free. G.

Operation for Urethral Stricture.—Goldman of Freiburg (*Lancet*, Dec., 1905) discusses the treatment of urethral stricture and strongly recommends the excision of the stricture with end to end anastomosis of the cut ends of the urethra. He shows that it is possible to remove from 4 to 8 c.cm. of strictured urethra and still be able to bring the cut ends of the canal together again, and what is more important still, to obtain quick and firm union, the dorsal vessels of the penis supply the cavernous tissue of the urethra with blood, there is practically no communication between the cavernous bodies and the urethra, hence we may dissect the whole of the bulbous urethra from the penis without running the risk of producing gangrene. Before the urethra is divided the whole of the strictured area should be dissected away from the surrounding tissues, the cut ends are then united with fine catgut over a soft catheter which is tied into the bladder. G.

The Diagnosis of Mediastinal Tumours.—Goldman of Freiburg (*Lancet*, Dec., 1905) describes the great difficulty of obtaining information by tracheoscopy in cases of tumours of the root of the neck or thorax. Its technique is so troublesome that tracheoscopy can be of little use to the general surgeon. He finds that X-ray photographs of the trachea afford valuable information as to its position. The trachea being filled with air appears as a faint white line on the negative; it can often be distinctly traced right down to its bifurcation, and shows on the negative if it is displaced by, or enveloped in, a new growth. G.

NOTE.—A summary will appear each week in the following sequence:—(1) "Recent Medical Literature"; (2) "Recent Surgical Literature"; (3) "Recent Gynaecological and Obstetrical Literature"; (4) "The Recent Literature of Anatomy, Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DIRECT REPRESENTATIVE FOR IRELAND.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me through your columns to thank most cordially all those who voted for me at the recent election of a direct representative for Ireland, and all those who worked for me so energetically. The result has been my defeat by four votes in a poll of 1,835, but the gratification remains to me that I have retained the confidence of so many of my professional brethren in Ireland.

Dublin.

I am Sir, yours truly,

WILLIAM THOMPSON.

BOOKWORM.—Our correspondent is advised to subscribe to Mr. Lewis' Medical and Scientific Library; herein he would be able to obtain the reading of all the books he is likely to require for a nominal subscription. We do not think *The Times* Subscription Library, to which he refers, stocks medical books to any extent, the fee also is, we understand, heavier in the latter.

THE REPORT OF THE REGISTRAR-GENERAL FOR IRELAND FOR THE YEAR 1904.

In view of our comments on the delay which has characterized the appearance of this report, the Registrar-General for Ireland has drawn our attention to the fact that for four months of this delay his office is not accountable. It appears that the report was in print and signed "for the Press" on August 12th last, and in spite of this some official red tape caused its appearance to be delayed for another four months. No one appears to be able to account for this delay, but it is evident that it was not the fault of the Registrar-General, with whom and with whose staff we sympathise in being deprived of the credit which should attach to them for the manner in which they have carried out their laborious task.

R. L.—Your letter is unavoidably held over.

THE GRESHAM LECTURES.

A correspondent writes mentioning the fact that Professor Symes Thompson, in drawing attention to the value of foods containing glycerophosphates, spoke of Sanatogen as a valuable remedy. This observation appears to have been amply borne out by the experience of many medical men, both in our own country and on the Continent.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 7th.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Mr. L. Gaister: Progress in Electric Lighting.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Horrocks, Mr. Targett, and Dr. Handfield-Jones. Short Communication: Dr. H. R. Spencer: A Second Case of Ovariotomy during Labour. The President (Dr. Dakin): Annual Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelsea Street, W.C.).—4 p.m. Mr. J. Clarke: Clinique. (Surgical.) 5.15 p.m. Lecture: Dr. J. Cantile: The Tropical Affections commonly met with in Britain.

THURSDAY, FEBRUARY 8th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m. Cases will be shown by Mr. A. Lawson, Mr. G. Coats, Mr. S. Morton, and others. 9 p.m. Clinical Evening.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—Papers:—Mr. O. Williams: The Ethics of the Profession in Relation to Syphilis and Gonorrhoea. Dr. J. J. Perkins: Tubercular Pleurisy—its Treatment and Diagnosis by New Methods.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m. Dr. Jellett: I. Advanced Carcinoma of both Ovaries; II. Double Prolapsus associated with the presence of a Four Months' Extra Uterine Foetus. Dr. B. Fenwick: Two Cases of Fibroid Uterus Complicated by Pregnancy. Dr. H. Macnaughton Jones: A Note on Crusts of the Vagina. Paper:—Dr. Jellett: Notes on two rare conditions met with in the Pelvis during Operation. The President: Inaugural Address.

CHILDHOOD SOCIETY AND THE BRITISH CHILD STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture:—Mr. J. C. Hudson: American Schools and their Relation to the Child and to Society. (Arranged by the British Child Study Association.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chelsea Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique (Surgical.) 5.15 p.m. Lecture:—Dr. F. J. Mc Ann: Abortion and Premature Labour. **ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN** (Leicester Square, W.C.).—6 p.m. Dr. M. Dockrell: Syphilis: Eruptions—Erythematous (I. Macular; II. Maculo papular); Papular (I. Miliary; II. Lenticular; III. Squamous; IV. Moist). (Chesterfield Lecture.)

FRIDAY, FEBRUARY 9th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Mr. B. G. A. Moynihan: A Review of 50 Cases of Cancer of the Stomach treated by Operation. Mr. J. Sherre: Three Cases of Intestinal Obstruction. Dr. Garrod and Dr. Langmead: Associated Malformations, including Transposition of Viscera. **MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chelsea Street, W.C.).—4 p.m. Mr. J. Horne: Clinique. (Throat.)

TUESDAY, FEBRUARY 13th.

MEDICO-LEGAL SOCIETY.—8.15 p.m. Paper:—F. S. Toogood, M.D. Alcoholism and Irresponsibility. Paper:—Albert Wilson, M.D.: The Medico-legal Aspect of Dual and Disjointed Personality.

Vacancies.

Bradford Poor Law Union.—Resident Assistant Medical Officer. Salary £100 per annum with rations, apartments, and washing. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22 Manor Row, Bradford.

Kent and Canterbury Hospital.—House Physician. Salary £90 a year, with board and lodging. Applications to the Secretary.

Kent and Canterbury Hospital.—House Surgeon. Salary £90 a year, with board and lodging. Applications to the Secretary.

Leeds General Infirmary.—Clinical Pathologist. Salary £200 per annum. Applications to Thomas Blair, General Manager.

Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Liverpool.

Manchester Ancoats Hospital.—Resident House Surgeon. Salary £100 per annum, with board, residence, &c. Applications to Saml. Baron, Secretary.

Manchester Ancoats Hospital.—Resident House Physician. Salary £80, with board, &c. Applications to Saml. Baron, Secretary.

Milton and Sittingbourne.—Medical Officer of Health. Salary £450 per annum. Applications to W. J. Harris, Clerk, 76 High Street, Sittingbourne, Kent.

Newcastle-on-Tyne Dispensary.—Two Visiting Medical Assistants. Salary £160 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Richmond District Asylum, Dublin.—Two Clinical Assistants. Salary £60 per annum, with furnished apartments and full rations. Immediate applications to Conolly Norman, Medical Superintendent. (See advt.)

Stirling District Asylum, Larbert.—Assistant Medical Officer. Salary £150 per annum with board. Applications to Medical Superintendent.

Appointments.

BARWELL, HAROLD, M.B. Lond., F.R.C.S. Eng., Surgeon for Diseases of the Throat, to St. George's Hospital.

BROWN, W. LANGDON, M.D. Cantab., M.R.C.P., Physician to the Metropolitan Hospital.

DICKMAN, H. G., M.B., M.S. Edin., Certifying Surgeon under the Factory and Workshop Act for the Holbeach District of the county of Lincoln.

FAIRFAX, N. P., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Act for the Innerleithen District of the county of Peebles.

FULTON, JOSEPH, L.R.C.P. and S. Edin., Visiting Surgeon, Belfast Union Infirmary.

GRAHAM, J., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Act for the Cokerthorpe District of the county of Cumberland.

GRANT, J. DUNDAS, M.D. Edin., F.R.C.S. Eng., Honorary Aural Surgeon to the Royal Otolaryngical Asylum, Busby, Heils.

IVENS, FRANCIS, M.B., M.S. Lond., Surgical Registrar to the Royal Free Hospital, Gray's Inn Road.

LEMIEUX, OSCAR E., L.S.A. Lond., Clinical Assistant to the Chelsea Hospital for Women.

NESBITT G., Resident Physician, Richmond, Whitworth, and Hardwicke Hospitals.

MACFARLANE, W. D., M.B., M.S. Glasg., Clinical Assistant to the Chelsea Hospital for Women.

REID, J., M.B., M.S. Aberd., Certifying Surgeon under the Factory and Workshop Act for the Doune District of the county of Perth.

RUTHERFORD, H. R. C., House Surgeon, Richmond, Whitworth, and Hardwicke Hospitals.

TURNER, A. S., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory and Workshop Act for the Beckenham District of the county of Kent.

WAUGH, ALEXANDER, L.R.C.P. Lond., M.R.C.S., Deputy Medical Officer for the Midsomer Norton District of the Clutton Union.

Births.

DOVE.—On Feb. 3rd, at Gothic Lodge, Leatherhead, the wife of W. B. Dove, L.M.A., M.B., of a son.

HODGSON.—On Feb. 3rd, at The Crescent, Salford, Lancs., the wife of Stanley Hodgson, M.D., B. Lond., M.R.C.S., of a son.

THYNE.—On Feb. 1st, at Tudor House, Barnet, Herts., the wife of William Thyne, M.A., M.D., of a son.

WALKER.—On Feb. 4th, at 35, Westgate, Peterborough, the wife of R. Alec. Walker, M.B., F.R.C.S., of a daughter.

WILLIAMS.—On Jan. 25th, at 37 Hope Street, Dunedin, New Zealand, the wife of Ernest Williams, M.B., of a daughter.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXII.

WEDNESDAY, FEBRUARY 14, 1906.

No. 7.

NOTES AND COMMENTS.

The Gramophone as Medicine. It is the wont of Medicine as a progressive science to press into her service the latest scientific discoveries. One of the most recent captives is the gramophone. The surgeons at a London hospital wishing to secure a record of the actual defects of articulation before operating on a boy with a defective palate, translated the voice into terms engraved on the wax cylinder of a gramophone. Then came the operation, and the subsequent improvement in speech could be accurately determined by comparing it with the reproduction. This ingenious test is clearly capable of extension. Not only improvement but changes for the worse in progressive nerve lesions and other maladies could be estimated in a similar manner.

A Royal Crèche. A SIGNIFICANT sign of the times is the interest shown by Royalty in all that concerns the health of the people. Last week one of those gracious acts that warm the hearts of the people towards the reigning family was performed by H.R.H. Princess Christian at Hammersmith, a suburb of London that possesses a large poor population. The appalling infantile mortality of that place has caused considerable heart-searching in the Town Council. Hence the visit of the Princess to a public meeting of that body.

A Home without Parents. THE crèche is to look after the infants whose parents are away at work. The daily absence of the father is the rule in working-class families, and where poverty is extreme or where women can readily obtain employment the mother frequently leaves home also. The risks to the children thus left to their own devices or to the haphazard supervision of a neighbour may be readily imagined. In Hammersmith alone, 1,800 women are employed in factories, 600 in incandescent mantle making, 1,000 in laundries, and 200 in sweetmaking. The municipal crèche is a move in the right direction, and British royalty could find no nobler and simpler means at hand of directly reducing the infantile mortality which is a blot upon our modern civilisation.

Nurs.'s Military Funeral. It is a pleasing indication of the more cordial *entente* that is springing up between the military and medical officers in the Army that appreciation for services rendered during times of sickness is being shown by military officers to the members of Queen Alexandra's Nursing Service.

We had occasion to chronicle some months ago the fact that a nurse in an Army hospital who died of typhoid was accorded the honour of a military funeral—the first time that such a tribute had been paid to a nurse. We expressed a hope at the time that the precedent would be followed, and we are glad, therefore, to note that a Miss Fitzgerald, a nursing sister at Aldershot, who died last week of pneumonia, was buried with full military honours. The pomp of bands, gun-carriages and uniformed men is never more impressive than at the grave-side, and the feeling of comradeship which these touching displays evoke can do nothing but good to both soldiers and nurses.

Arsenic in Beer. A CASE of arsenical beer poisoning has been reported by the Medical Officer of Health for the City of London. Dr. Collingridge was notified of the fact by a medical man, and it was found that the victim had been drinking large quantities of "four ale." On analysis, the particular brew was found to contain a trace of arsenic less than 1'100 grains per gallon. In proof of the diagnosis arsenic was found in the man's hair, but surely traces of arsenic are commonly found in hair, apart from any question of poisoning. Now that the purity of glucose is a matter of rigid scrutiny, the chief sources of arsenic in beer are malt and hops. That conclusion must be somewhat disquieting to the pure beer enthusiasts. It is a matter of interest to know what must be the fate of patients who are often dosed with arsenic for long periods. If minute traces cause such disastrous effects, what must result from the far larger doses administered under the direction of the medical man?

A Strike amongst Medical Men. THE parish doctors of Austria are still on strike, and it is reported that there has been an alarming consequent increase of the death-rate. The reason of their discontent is not hard to gather when we learn that the Governmental fee is twopence for each case of infectious disease, which entails a detailed diagnosis. Let us hope that the Austrian movement will result in better pay for medical men all round. It has become too much of a fashion for governments and private citizens to do good vicariously at the expense of the medical man. Possibly the revolt will travel westward to the United Kingdom, where much beggarly exploitation awaits the besom of reform. It would indeed be a spectacle for gods and men were the medical profession of our own country to organise for the raising of ill-paid club, union, and other contract practice.

LEADING ARTICLE.

WHAT IS WHISKEY?

THE problem of food adulteration, set on foot a generation ago by the indefatigable genius of the late Dr. John Hassall, is still with us. Notwithstanding the crucial importance of maintaining the highest possible standard of purity in food and drink, there can be little serious doubt that the community is at the present moment being defrauded in pocket and injured in health by the extensive adulteration of the articles in question. The fact of the matter appears to be that the progress of public health involves one long battle against the vested interests that batten on the misery, the vice, the poverty, and the helplessness of the masses. Hitherto the tendency has been to focus attention upon articles of food, and to a great extent to ignore the vitally important question of the purity of alcoholic liquors. Years ago a series of spasmodic prosecutions of publicans in London revealed wholesale adulteration of a most serious nature. It is more than probable that the abuse still exists, but Excise prosecutions are just as rare as police proceedings against licensed victuallers. And so "the trade" is allowed to pursue its own sweet will, and to strengthen its position from time to time by the enormously powerful brewers' and distillers' influence at work in both Houses of Parliament. With all this social tangle the medical profession is deeply concerned, inasmuch as the evils of intemperance profoundly affect the moral and the physical health of the community. It would be impossible to imagine any great public health gospel that did not put the control of the liquor trade in a foremost place. Of late, medical men have turned their attention to some of the practical aspects of the question. One of the most important steps achieved within recent years was in the legal decision that said brandy must be made from the juice of the grape. A similar approach to a standard is still wanting as regards whiskey, but litigation is pending that it is to be hoped will settle the point once and for all in a satisfactory fashion. The solution of the problem is of importance to those who find it necessary to prescribe this particular form of stimulant. We will endeavour to state concisely the antagonistic and conflicting views which are held on the subject. There are two different substances advertised and offered for sale under the designation. First there is the old-fashioned all malt whiskey made in a pot still, and there is the more modern silent spirit made in a patent still and flavoured to taste. The ingredients used vary in the two cases, and there are also certain minor but not essential differences between the Scotch and Irish varieties of pot-still whiskey. Scotch whiskey is a spirit distilled in a pot-still from malted barley mixed, in some cases, with a little unmalted barley and wheat. In the case of Irish whiskey, in addition to the malt, certain other indigenous grains are used, the term "indigenous" being employed in

the definition to exclude rice and Indian corn, which are not admissible. In Ireland, in the process of distillation, anthracite coal is employed as a source of heat, whilst in Scotland they use peat, the fumes of which, passing up through the perforated floor on which the malt rests in the kiln, gives it that peculiar flavour which is its great characteristic. The patent-still spirit is made from Indian corn, rice, or potatoes—in fact, almost any substance containing starch will suffice. The product is known as "silent" spirit from the fact that it gives no clue to its origin, so that if properly flavoured it may be made for brandy, whiskey, or anything else of a spirituous nature. The pot-still product, however, is redolent of its origin, and is whiskey and nothing else. There is also a difference in chemical composition, for whilst silent spirit is simply ethylic alcohol, pot-still whiskey contains a number of bye-products of which ethers, the higher alcohols, and certain acids and aldehydes are the most important. Amongst chemists these bye-products are sometimes spoken of technically as "impurities," but this term is not employed in the ordinary and popular sense of the word; in fact, so far from their being injurious, it is on their presence in adequate proportions that the virtues of whiskey as an alcoholic stimulant depend. Silent spirit can be produced at a considerably less cost than pot-still whiskey, and little by little the custom has grown up in this country of selling the substance with a certain admixture of real whiskey under the name of whiskey, with, perhaps, the addition of some fancy title suggestive of a Scotch or Irish origin. This, it is contended, is a fraud on the public, seeing that it is sold to the prejudice of the purchaser, and is not of the nature, substance, and quality demanded. This is practically the question which has been under the consideration of Mr. Fordham at the North London Police Court since November 6th last, and still remains undecided. With the commercial aspect of the subject we are not concerned, but medically it is to us a matter of considerable moment. Dr. Murrell, of the Westminster Hospital, the only member of our profession who has yet given evidence, pointed out that during the last twenty years there had been a considerable change in the form of alcoholic stimulant employed and that whilst formerly brandy was universally prescribed, it is now very largely superseded by whiskey, the explanation offered being that good old well-matured brandy is difficult to obtain. Whiskey is used to stimulate the heart, to dilate the blood vessels, and ward off collapse in many of the acute specific diseases, such as enteric fever and pneumonia. It is also used in various forms of dyspepsia, especially the atonic dyspepsia of the aged and the gouty, when wines and other saccharine beverages would prove harmful. We attach much importance to the presence of the bye-products in whiskey, and silent spirit, which differs but little from the rectified spirit of the Pharmacopœia, has not the same

therapeutical effects. Whiskey ought to be pot-still and made from malted barley, with possibly, in the case of Irish barley, the addition of some unmalted whiskey and other indigenous grain. A point to which sufficient attention has not been paid is that all whiskey used for medicinal purposes should be of some age and well matured. It is difficult to lay down hard and fast rules, but whiskeys fifteen to twenty years old are readily procurable and at a moderate cost. There is no doubt that whiskey improves by keeping, but there is no evidence that a similar change occurs in patent silent spirit. In Scotland, both doctors and patients are reputed to be good judges of their national beverage, but in England many people who are supposed to be life-long whiskey drinkers have in all probability never tasted the real article. The farther north the "fatter" the whiskey; in other words, in Scotland "all malt" is drunk, whilst in the South the consumer has to be content with a mixture containing a large percentage of the artificial substitute.

NOTES ON CURRENT TOPICS.

Professor Behring's "Tuberculase."

THE recent address of Professor Von Behring to the German Agricultural Council, on his researches into the prevention and cure of consumption, appear to have roused a good deal of criticism amongst his fellow scientists. There seems to be a somewhat prevalent view that his claims to curative treatment have been premature and founded on theory. Nor are his latest announcements likely to escape serious criticism. He claims to have made a serum which will protect calves from tuberculosis. He further states that by means of a curative agent called "tuberculase," he can cure cows, a fact shown by the disappearance of tuberculosis germs from their milk. His third claim is that by means of a serum he can cure tuberculosis in the human subject. While it would be unwise to form any opinion as to the ultimate value of Professor Behring's work, it is nevertheless much to be regretted in the interests of mankind at large that he was tempted to announce his beliefs before they were capable of definite scientific demonstration. Experience has repeatedly shown, however, that even our greatest minds may walk open-eyed into the pitfall of anticipation.

Pre-Arranged Appointments.

COMPLAINTS frequently are brought to our notice by candidates for medical appointments that though such posts are advertised with circumstantial detail and every appearance of *bona fides* they are in reality not vacant at all, because the body in whose gift they lie have already made up their minds as to whom they will elect. This is a genuine grievance, and one that should be removed. There are often good reasons, such as personal knowledge and previous services, that entitle a committee to regard a certain man as

thoroughly suitable for a position; in that case no advertisement should be issued, or, if issued, a clause should be put in to indicate that the notice is only formal. Occasionally there are less worthy reasons, but even then it is not fair to invite competition for what is practically a close appointment. Many candidates for house-surgeoncies and similar posts are put to much inconvenience in obtaining testimonials and recommendations, and even waste weeks of valuable time waiting for a possible summons to appear, when all the time there has been no demand for their services, and the advertisement has only been issued to comply with a by-law of an institution or a resolution of a committee. To say that an appointment is vacant when it is practically filled is substantially to say what is not true, and the practice of so-doing reflects no credit on those who do so in order to give an appearance of fairness to an unfair proceeding.

Medical Black List.

It would be interesting to find out which class of the community is most generally and regularly swindled, but in the absence of demonstrable evidence we strongly incline to the idea that medical men are. Excluding "God's poor" and the "poor devil" whom the doctor is always willing to do his best for, irrespective of payment, there are a vast number of people who systematically neglect the payment of their doctor, or, rather, their doctors, for they successively patronise the whole faculty in the neighbourhood. It should be possible, by means of combination and organisation, for medical men to guard themselves against swindlers of this kind, and we recommend to their notice the action of the doctors of St. Louis who have recently decided to issue, for mutual protection, a black list containing the names of people who owe them money. There are supposed to be no less than fifteen thousand names ready for the first number which is to appear shortly, and to these there will be added monthly those of other *chevaliers d'industrie* who prey on the profession. Were such a list arranged in every town for private circulation among practitioners, it would pretty effectually put a stop to the major portion of the bare-faced robbery that deprives an honourable body of men of the reward for their labours.

The "Tribune" and Advertisements.

OUR new contemporary, the *Tribune*, has been well received in all quarters, a fact which is not without encouragement for those who feared that the days of responsible and sober journalism had passed away. We note with particular satisfaction that the proprietors announce that they intend to exercise a strict supervision over their advertisement columns, and will refuse insertion to anything of a fraudulent or offensive character. Moreover, they will, on proof, stop the insertion of any advertisement which does not accurately describe the article sold. It is a bitter, but by no means supererogatory, comment on the com-

mercial morality of a large section of the newspaper world that a notice of this kind should be deemed necessary, and, without wishing unduly to praise a person for doing what is plainly his duty, we may remark that this determination of the proprietary of the *Tribune* does them great credit. But, alas for the frailty of man, we have only to turn over the pages to find the usual proportion of quack medicine advertisements, garnished with the usual high falutin' suggestions and suppressions. On page 4 of the issue of February 8th, there is an advertisement of "Anturic Salts, Ltd.," headed "Rheumatism's Danger Signals," which describes in purple language the dangers of rheumatism and gout, the prodromal symptoms of these affections, and their method of cure by using "Anturic Salts" in the bath. We select the following statements:—"Anturic Bath Salts is (*sic*) the real remedy. . . It positively cures in the bath. . . Drugs are unnecessary, and there is no need to diet. . . Anturic Bath Salts cures (*sic*) by penetrating the skin, dissolving the poisonous uric acid salts, and discharging them from the system. . . . Whether the complaint is in its early or advanced stage, the result is always the same, because Anturic Bath Salts completely eradicate the cause." We would ask the proprietors of the *Tribune* whether they are of opinion that such phrases, "accurately describe the article sold," or, indeed, any article in the compendium of human philosophy.

Children and Sexual Questions.

THE right and the wrong way of letting children understand the relation of the sexes is one of the highest importance to society, both from the point of view of general morality and from that of the prevention of venereal disease. The general *laissez-faire* policy adopted by parents cannot be too strongly condemned, for it makes for guilty knowledge and practice among boys, and is accountable for a certain amount of seduction and much married misery among girls. The evils of this course are being strongly shown up by medical men in America, and the case for responsible explanation and information on the part of the parent is forcibly insisted upon. A book by Dr. Wilson, of Philadelphia, has lately been published with a view to guiding parents as to how the question may best be approached, and the cognate subjects of venereal disease and illegitimacy dealt with sensibly—and without prudery. The wisest plan appears to be to approach the subject from the biological aspect, tracing the methods of reproduction of plants and the lower animals, and thence to pass through the higher animals till man is reached. The drawback to this method is that it pre-supposes a certain acquaintance with biology on the part of the average parent, which in fact he is not possessed of. A very little study, however, will enable him to acquire it, and to medical men in relation with their own children and those of their patients who seek advice on the point the subject presents no difficulty. Incidentally

it may be noted as one of the advantages of teaching science in schools that the sexual relationship naturally arises and is as naturally disposed of.

Nursing on its Dignity.

A MEETING of the Royal British Nurses' Association was held on February 7th to discuss the Bill for the State Registration of Nurses, which the Association propose to introduce into Parliament this session, and a very lively meeting it was. Trouble began by the chairman, Sir James Crichton-Browne, announcing that it had been discovered that through technical flaws, the last meeting of the Association was irregular, and it was therefore proposed that its proceedings should be rescinded. Several ladies espied in this an attempt to stop discussion, and loud clamour arose. Eventually the proposal was passed on a promise being given that the Bill should be debated clause by clause, and the meeting settled down to business. However, when the composition of the proposed Board came to be discussed, the excitement rose high again, as a section of the audience felt that too many doctors were to be on the Board, and that this arrangement would tend to the undue subjection of the nursing element. The excitement, which was gradually working up, culminated in the statement made by one of the nursing representatives that many doctors knowingly sent out women of bad character as nurses, and that under the proposed constitution they would be able to put such women on the "Register." Nor did the protests of the audience succeed in inducing the lady to retract her words. The next speaker, also a lady, said that she would rather be governed by medical men than by the turbulent women who were present, and Sir James Crichton-Browne, aptly remarked that the Association need not fear any extreme avidity on the part of doctors to snap up seats on the Board.

State Children.

ALL good economics start from the individual as surely as they end with him; that is to say, that the individual welfare is, or should be, the aim of all State organisation. The political problem is how best to accomplish this end, but it is certain that no system which does not regard the well-being and good upbringing of children can be sound. Into our old State this truth is beginning to make headway, but it is difficult to find the best medium for its expression among old prejudices and long-standing ideas. The Colony of New South Wales, which, like all the Australian colonies, wants population first and foremost, has risen to a high sense of the value of children and to its responsibility for their welfare. A State Children's Relief Board was recently created to take charge of all children who either had no parents or bad parents, or were bad in themselves. Under the guidance of the Hon. Dr. Mackellar, an enthusiastic administrator, this Board has succeeded in doing great things for

such children. It has now some seven thousand children under its care, about half of whom are placed in respectable homes under good guardianship or in State institutions, whilst the other half are with their mothers or relatives under a strict system of instruction. Many of the latter are illegitimate, and the Board does not hesitate to aid indigent mothers with pecuniary help when they are unable properly to tend their children. The aim of the Board is to promote the physical and moral well-being of children generally, and it guards children in all departments of life with a jealous eye. When parents are considered unfit to rear children in a decent manner they are taken from them and placed under proper guardianship, the parents being compelled to aid in their maintenance. Special Children's Courts are in existence for the trial of juvenile offenders, and parents are punished for contributing by wilful default to the delinquency of their offspring. The Board is receiving warm support from the medical profession in the Colony.

Yellow Fever via the Panama Canal.

HITHERTO the Pacific Islands have been free from the scourge of yellow fever. This fact is curious when we consider that they possess, in common with the West Indies, the tropical temperature necessary for the incubation of the *Stegomyia fasciata*, which harbours and transmits the parasite of yellow fever. The only absent link is the specific micro-organism which, according to Mr. V. L. Kellogg, of the United States Fisheries Bureau, has not been able to survive the conditions of the voyage round Cape Horn, hitherto necessary to transit from the West Indies to the Pacific Islands. All that will probably be changed by the completion of the Panama Canal, and the yellow fever organism may be transmitted from West to East in a state of fell activity. In that case the result would be like putting a light to dry heather. If trade be established by the new route, it is, moreover, difficult to imagine how the risk could be averted by any known sanitary precautions.

Force of Life Company.

QUACKERY, for some curious psychological reason, finds a peculiarly congenial soil in the American temperament, and the number and variety of patent medicines, osteopathic cures, nerve treatments, and illegitimate medical enterprises of one kind and another is positively astonishing. It would be difficult to say which has the most dupes, but the "Force of Life Company," which is said to have treated something like a million patients, must, we imagine, very nearly have attained that distinction. The vast ramification of its operations is only equalled by the appalling simplicity of its methods of "cure"—most of these being of the lowest order of imposture on credulity. American citizens of high position and presumably intelligence are amongst its *clienteles*, and the profits have been

enormous. President Roosevelt has turned his personal attention to this huge swindle, and has lately ordered the arrest of some of the directors for using the Post Office to defraud. Fortunately in America the Post Office has regulations of its own against the transmission of fraudulent advertisements—an example which our own department might well copy—and now that the prosecution has been initiated it may be hoped that the "Force of Life Company" will be dealt with according to its deserts.

PERSONAL.

H.R.H. PRINCESS CHRISTIAN attended a meeting held in the Hammersmith Town Hall on the 7th instant to consider the possibility of founding a crèche in the neighbourhood.

SIR JOHN BATTY TUKE has been re-elected by a large majority as Parliamentary Representative of the Universities of Edinburgh and St. Andrews. His record of work in favour of the medical profession in the last Parliament more than warrants the confidence of the electors.

THE Chair of Forensic Medicine in Edinburgh University, rendered vacant a month or two ago by the resignation of Sir Henry Littlejohn, has been filled by the appointment of his eldest son Dr. Harvey Littlejohn, lecturer on Forensic Medicine, Surgeons' Hall, Edinburgh.

WE learn that Dr. Stocker, medical inspector at Glasgow under the Emigration Department, has been appointed to succeed Dr. Spooner as chief medical emigration officer at the Port of Liverpool.

PROFESSOR VON BERGMANN, the well-known Berlin surgeon, has been recently elevated to the peerage.

SIR E. P. WILLS has generously given £1,500 for the endowment of a bed at the Bristol General Hospital.

THREE lectures on the physical anthropology and ethnology of British New Guinea will be delivered at the Royal College of Surgeons, by Professor Charles G. Seligmann, on February 12th, 14th, and 16th. The lectures will be illustrated by the lantern and will begin at 5 p.m.

MR. JAMES CRAWFORD MAXWELL, District Commissioner, who is returning to Sierra Leone, is a graduate of Edinburgh University. He was formerly in the Army Medical Service, and holds the West African medal with clasp, 1898-1899. During that campaign he was severely wounded in the neck in one of the brushes with the natives. On another occasion a native at short range deliberately fired at him with an old flintlock musket. Fortunately the aim was not true, and a miscellaneous assortment of broken metal lodged in the body of a carrier, who died within twelve hours.

PROF. ROBERT BOYCE, F.R.S., has kindly consented to give an address at the fifteenth International Medical Congress on "The Prophylaxis of Yellow Fever as the result of the 1905 Epidemic in Central America and New Orleans." This address will take the place of the communication promised by Sir Patrick Manson, K.C.M.G., who is unavoidably prevented from attending the meeting at Lisbon.

THE second annual dinner of the Association of Medical Diplomates of Scotland will take place on the 23rd instant at the Trocadero, London, when Dr. McGillivray, President of the Edinburgh College of Surgeons, will be the principal guest, together with Mr. Tweedy, President of the London College. Tickets, 10s. 6d. each, may be obtained of the Dinner Secretary, Dr. Féré, Northampton Square, London, W.C.

A CLINICAL LECTURE

ON

GONORRHOEAL RHEUMATISM AND GONOCOCCIC INFECTION.

Delivered at the Westminster Hospital.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician and Lecturer on Medicine at the Hospital, and Examiner to the University of Aberdeen.

GENTLEMEN,—I beg to present to you to-day for your consideration certain cases of gonorrhœal rheumatism, and the first point I wish to impress on you is that there is no such disease, but that it is simply a manifestation, or symptom if you like, of a general gonococcic infection. In previous lectures I have demonstrated to you, and I hope to your satisfaction, that both in tuberculosis and in pneumococcic infection almost every organ and tissue of the body may be involved. It is pretty much the same with the gonococcus; it is a disease of the septicæmic type and the gonococci are being constantly conveyed to different parts of the body through the agency of the blood and the lymph channels, exciting secondary local manifestations not only in the joints, but elsewhere. The site of inoculation is usually the urethra in men, the vagina or os uteri in women and the vulva in little girls. The conjunctiva is often the starting point in children; less commonly in adults. Rectal and buccal cases have been recorded on the Continent, but with these we need not deal. Some enthusiastic observers have injected themselves subcutaneously and experimentally with cultures, and have been duly rewarded with elevation of temperature, malaise, pains in the muscles and inflammation of the joints. It seems a useless and unjustifiable experiment, for so much more can be learnt by simple clinical observation. The gonococcus under favourable circumstances produces its specific effects by whatever channel it effects its entrance into the body, and gonococcic infection does not of necessity involve a preceding urethritis, although it is one of the commonest forms of origin. Incidentally it may be noted that the gonococcus is most readily absorbed from the urethra when there is a stricture.

Returning to our gonorrhœal rheumatism it is incorrect to speak of it as a rheumatism or even as an arthritis, for it is more commonly a synovitis with effusion into the sheaths of the tendons. It differs from rheumatism in every essential particular and is not amenable to the same methods of treatment. The first attack may or may not be preceded by a specific gonorrhœal discharge, but when such is the case subsequent attacks may follow a urethritis in which gonococci are absent or are not readily detected, and still later there may be attacks without any urethral discharge. The interval which elapses between a gonorrhœal infection and the onset of the arthritic manifestations varies much in different cases, it may be only a few days after the first appearance of the discharge, or it may be delayed for some weeks. The onset is not sudden, and is rarely ushered in by a rigor. There is little elevation of temperature, and when it is hectic in character it may be taken as an indication that there is a mixed infection. In uncomplicated cases there are the usual indications of constitutional disturbance such as headache, furred tongue, loss of appetite, constipation and pains in the limbs, but they are transitory and never severe. There is a common opinion that gonorrhœal rheumatism is essentially a man's disease, but it is met with quite as commonly in women, and then is usually ascribed to some other condition, such as gout or rheumatoid arthritis. Another prevalent opinion is that it is a monoarticular affection and that the favourite site is the knee. It is true that the knee frequently suffers, but the joint from its exposed situation and from the fact of its being imperfectly covered by other tissues is liable to arthritides of all kinds. This proclivity is not

characteristic of gonococcic infection, and is not more pronounced than in other diseases in which the joints are affected. The hip, wrist, elbow, shoulders, and hand are frequently involved. Certain joints not usually attacked by rheumatism may be implicated, notably the temporo-maxillary, the sacro-iliac and the sternoclavicular. The onset is usually marked by swelling and pain, the swelling being due to the effusion of serum into the joint cavity and its surrounding tissues. There is little redness or blush on the surface, and the pain, although severe is not comparable to that of gout or acute rheumatism. Exceptionally, however, arthralgia is the prominent symptom, and there may be little swelling or other evidences of inflammation. Metastasis is not common, and there is no tendency for the inflammation to shift from one joint to another, a point of diagnostic importance. Effusion into the tendon sheaths is of frequent occurrence, especially when the wrist and ankle are involved. The dome-shaped swelling of the dorsum of the hands is common and characteristic. Affections of the fasciæ are frequent, and the plantar fasciæ are especially liable to suffer, giving rise to flat-foot. Cases of pain in the heel, which cannot be referred to a short os calcis or to gout, are due to this cause. Another symptom is pain in the muscles, which may be mistaken for chronic myositis or rheumatism. When it attacks the lumbar fasciæ it is readily confounded with lumbago. The effusion into the joints rarely runs on to suppuration, although the complication may occur in tuberculous subjects, and is not uncommon in pyæmic gonorrhœa. The inflammation as a rule soon subsides, but after repeated attacks the joints may be irremediably damaged, and may be rendered useless by fibrous adhesions. The determination of the particular joint affected often depends on some accidental cause. A man plays football a few weeks after contracting a gonorrhœa and the disease attacks his ankles; his friend, under similar circumstances, carries a parcel to oblige a lady and gets it in the hand. I have known it occur in a medical man in the right wrist after a heavy "placental" case. The determination of site is not peculiar to gonococcic infection, but is seen in gout and in other arthritic affections.

The articular manifestation is but one evidence of gonococcic infection, and there may be accompanying conjunctivitis, iritis, and sclerotitis; of less common occurrence but well recognised sequelæ are endocarditis, pleurisy, meningitis, neuritis, especially of the sciatic variety, and general arteritis. Many cases of arterial degeneration are due to this infection; in fact there is no tissue of the body which can claim immunity from its attacks. Even subcutaneous abscesses are sometimes formed, gonococci being found in the pus. This, it must be admitted, is a rare complication, for the gonococcus alone rarely leads to purulent formation. On the other hand the chances of a mixed infection are great, considering the facilities which are offered for the invasion of pyogenic organisms from a gonococcic lesion.

I should like to say a few words about gonococcic iritis because it is a subject on which there seems to be some difference of opinion. Some people have even gone so far as to say that this form of iritis does not exist, but that is an entire mistake. The two forms of iritis which rest on a sure and firm basis are the syphilitic and the gonococcic. The rheumatic is nebulous, and when a man comes to you with a diagnosis of gouty iritis you had better inquire into his past history and

that will probably solve the mystery. Gonococcal iritis is concurrent with the arthritic affection, or at all events comes on about the same time. I have, however, known it appear some months after the subsidence of the joint trouble and quite apart from any fresh infection.

In women, in addition to these symptoms we get the effects of direct continuity of infection, such as salpingitis, metritis or ovaritis. A large proportion of cases of sterility are due to gonorrhœa. The husband contracts gonorrhœa in his bachelor days and although free from all acute symptoms, still retains a hardly perceptible gleet, which is quite sufficient to account for the mischief. These women are usually œmic, destitute of energy, and incapable of much physical exertion. They are treated for womb trouble, and undergo curetting and other modes of treatment favoured by gynecologists. They suffer from many of the general symptoms met with in the victims of "larval syphilis." The co-existence of a vaginal discharge, whether acute or chronic uterine or ovarian mischief, and an inflammatory condition of one or more joints should always excite suspicion.

The connection of gonococcal infection with the invasion of tubercle is well-known. In some cases of gonorrhœa the tubercle bacilli as well as gonococci have been detected in the discharge. This is probably the explanation of some cases of genito-urinary tuberculosis of the "ascending" variety. In man the testicle, epididymis, prostate, bladder, or kidney may all suffer. In much the same way joints which have undergone gonococcal inflammation may at a later stage become tuberculous.

Gonococcal arthritis of conjunctival origin is common in young children. Clement Lucas has recorded a series of cases which show that ophthalmic rheumatism may attack infants either as an acute arthritis accompanied by much pain, swelling and redness, or as a subacute synovitis, with effusion. The original ophthalmia may be due to an inoculation from the vaginal discharge of the mother at the time of birth, or as in the epidemic form which occurs in children, from infected towels or linen. In these cases the joint affection develops about the end of the second week from the infection. The arthritis speedily clears up, and rarely leaves permanent mischief. This form of infection is rare in adults, but the following is a case in point:—

A man, æt. 25, was brought to Westminster Hospital in an ambulance on Sept. 21st, 1904, suffering from what was supposed to be rheumatic fever. The history was that on the previous day, being then in perfect health, he had an attack of acute double conjunctivitis followed in a few hours by inflammation of the right wrist and the left knee. The patient on admission had a temperature of 101.8° F., and was sweating profusely. On examination it was found that the wrist itself was not involved, but that there was considerable effusion into the cellular tissue of the dorsum of the hand, which was dome-shaped and boggy, a condition which might readily have been mistaken for chiragra. The knee was swollen, red, hot and tender, but contained no fluid. On the following day the inflammation in the left knee subsided and the left elbow and the right knee were attacked. The temporo-maxillary, sacro-iliac, and sterno-clavicular articulations were not implicated. The patient was placed on full doses of salicylate of sodium, first of the synthetic and then of the natural salt, but without amelioration of the symptoms, the temperature ranging from 100° to 102° daily for many weeks. There was no cardiac complication and no pericardial rub or effusion could be detected. There was no tonsillitis and there was no history of syphilis, gout or alcoholism. A gonorrhœal history was suspected, but the patient denied any attack past or present, and squeezing the urethra gave a negative result. The urine was of specific gravity 1020, acid, and contained no albumen. No flocculi were at any time observed in it. There was a history, at the age of 22 years, of an attack of acute rheumatism

of some weeks' duration. The œdema of the hand continuing, the fingers were carefully examined but no abrasion or wound could be detected, and the temperature was not of a hectic type. The eyes were treated with boracic acid lotion, but without improvement in their condition, and on October 7th, in addition to the conjunctivitis, there was much ciliary congestion. The patient having derived no benefit from the salicylates was given first aspirin and then iodide of potassium in full doses, but again without benefit. On the 10th, there being effusion into the right knee-joint, it was aspirated and the fluid examined, but no micro-organisms were found in the films, and there was no growth in any of the media after four days. On the 18th there was a renewed attack of acute purulent conjunctivitis of the left eye, for which a 5 per cent solution of argyrol was prescribed, the application of which promptly relieved the inflammation. The conjunctival secretion was examined, but no gonococci were found. The patient had several subsequent attacks both of conjunctivitis and arthritis of gradually decreasing severity, and he was discharged on November 15th, relieved of all his symptoms.

This case of multiple arthritis presented many points of interest and much difficulty was experienced in arriving at a definite diagnosis. In favour of its being acute rheumatism was the history of a previous attack, presumably rheumatic in origin, although on that point there was no positive evidence. Against this theory was the absence of an initial tonsillitis, the rebelliousness to the salicylates, the cellulitis of the dorsum of the hand, and the freedom from cardiac complications. The diagnosis of gout was not seriously entertained and, apart from other considerations, the duration of the attack negated that theory. From the first a suspicion was entertained that it was a gonococcal infection and the effusion into the tendon sheaths supported that view. The absence of a urethral discharge could not be held to outweigh the general evidence in favour of that theory. The fact of gonococci not being detected in the fluid from the knee-joint could not be regarded as conclusive, and probably the conjunctival secretion was examined too late in the progress of the case to carry much weight. It is practically certain that this was a true case of conjunctival arthritis, the conjunctivæ being inoculated with an attenuation of gonococcus. How the infection took place it is needless to discuss.

Gonococci in the ophthalmic secretion were discovered by Darier in 1889, and demonstrated by Deutschmann in the fluid from the inflamed joints in 1890. The synovial membranes should always be carefully examined. The remote effects of the infection are probably due to gonotoxin. The purulent form may be associated with streptococci or staphylococci. The diagnosis of gonorrhœal rheumatism rests on (1) The history of gonococcal infection or on the presence of obvious gonococcal lesions; (2) the implication of certain joints not usually affected in other forms of articular disease; (3) the absence of metastasis; (4) the involvement of the fasciæ and tendon sheaths. In many chronic cases the diagnosis is difficult and must remain uncertain. The patient cannot be made to remember whether or not he had a urethritis, and if there is a history of an attack it was so many years before and so long an interval has elapsed that it is doubtful if it can be regarded as an antecedent cause. In the case of married women the difficulty is enormously increased, and it is often inadvisable to inquire too curiously into the antenatal history of either husband or wife. Bacteriological investigation in these cases, unless the infection is recent, throws but little light on the subject. It is difficult to find the gonococci in late cases, probably because they are ousted by more robust pathogenic organisms. Gonotoxin inhibits phagocytic action and so predisposes to mixed infection. It is well to recognise the fact that gonorrhœa is very easily overlooked in women. It is usually regarded as an acute vaginitis, but it much more frequently involves the ducts of the vulvo-vaginal glands and the parts imme-

diately surrounding their orifices. Unless the urethra is implicated it gives rise to little scalding or inconvenience. The great danger arises from the fact that the cervix becomes early infected and the inflammation spreads upwards beyond the range of local applications. The result of gonococcal salpingitis is the sealing up of the fimbriated extremities of the Fallopian tubes by adhesive inflammation. These people bear no children, or are at the best "one-child women." The child, too, is rarely robust or of good quality.

The prognosis in cases of gonorrhœal rheumatism is on the whole favourable, although from time to time cases are seen in which there is a recrudescence of the arthritic manifestations when the patient takes up his abode in a damp climate and especially on a clay soil. The outlook is distinctly less favourable in those who have already suffered from one or more attacks of acute rheumatism, especially when there is cardiac mischief. Several cases of fatal gonococcal ulcerative endocarditis and gonococcal pyæmia have been recorded, a condition which has been mistaken for enteric fever, malignant disease of the prostate or purulent cystitis. There is one other point to remember with regard to prognosis, and that is that gonorrhœa is a much more serious disease than syphilis, that is when the latter is of home manufacture. The Egyptian and other foreign varieties are apt to be virulent and cannot be recommended. There is one important difference between syphilis and gonorrhœa; the syphilitic organism affords protection, although admittedly incomplete, whilst the gonococcus not being of a robust nature fails to maintain its influence and leaves the unfortunate patient liable to future invasions. What is required is a protective gonococcus, but as yet it has not been cultivated.

With regard to treatment it is easier to enumerate drugs which are inefficacious than to find those which are valuable. When the disease follows a urethritis that must be cured, and when there is a stricture that must be dilated. When the eye is the point of entrance of the poison the instillation of nitrate of silver or of argyrol is necessary. The affected joints should be kept absolutely at rest and hot fomentations and poultices should be employed. A good poultice is made with equal parts of linseed meal and precipitated sulphur. Counter-irritation with iodine or capsicum or rubbing in a liniment of aconite, belladonna and chloroform will be found useful. In chronic cases the iodides internally in large doses may do good, especially when the pain is worse at night. The ammoniated tincture of guaiacum is sometimes useful, and sometimes general tonic treatment with arsenic and iron is indicated. Should the fluid show no signs of absorption the joint may be aspirated and injected with from a drachm to a drachm and a half of a 1 in 4,000 solution of corrosive sublimate, or with the same quantity of a 5 per cent. solution of carbolic acid. In chronic cases affecting the wrist, wearing a tightly-fitting strap does good, probably by keeping the parts at rest. Hot air baths and electricity may be recommended, and when all else has failed surgical treatment should be resorted to, followed by the careful selection of a suitable climatic station.

The choice of an alcoholic stimulant in these cases is a matter of some moment. To deny the patient alcohol in any form is a considerable deprivation, and is not attended with good results. Wines and other saccharated beverages are clearly inadmissible. The best drink is an antique pure Highland whiskey distilled from the finest malted barley and freely diluted with water. The quantity to be prescribed and the frequency of administration is a matter for individual consideration. It need hardly be said that the ordinary public-house whiskey of the silent spirit description is a powerful toxic agent. To get good whiskey you must go to Scotland, and even then a certain discrimination is necessary.

The points to remember about gonorrhœal rheumatism are:—

1. That it is not rheumatism and has nothing to do with rheumatism.

2. That it is not essentially an arthritic affection, and that the brunt of the disease falls on the fasciæ and on the tendon sheaths.

3. That it is not a monarticular affection and that many joints and their surrounding tissues may be involved.

4. That the temporo-maxillary, the sacro-iliac and sterno-clavicular articulations are frequently implicated.

5. That it need not be preceded by a urethritis, specific or otherwise.

6. That it is not solely a man's disease, but that it is common in women and children.

7. That iritis and other eye affections are common results of gonococcal infection.

8. That in women it is frequently associated with salpingitis, metritis, ovaritis, and other manifestations of gonococcal infection.

9. That the infection is one of the most frequent causes of sterility.

10. That marriage frequently revives an old and latent gonococcal infection.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The Lecture in next week's will be by Arthur J. Whiting, M.D., M.R.C.P. Lond., Dean of the North-East London Post-Graduate College, Assistant Physician to the Tottenham Hospital, and to the Mount Vernon Hospital for Consumption, on "Hemiplegia."

ORIGINAL PAPERS.

OBSERVATIONS ON PERCHLORIDE OF MERCURY AS A DISINFECTANT.

By DAVID SOMMERVILLE, B.A., M.D., D.P.H.
M.R.C.P.,

Lecturer in Public Health, King's College, London,

AND

J. T. AINSLIE-WALKER, F.C.S.

THAT there is wide scope for investigation in the field of disinfection, especially in relation to the comparative values of different disinfectants, is daily becoming more manifest. Very erroneous views of the germicidal powers of many disinfectants are still abroad, and whilst we remain without an officially accredited method of testing the efficiency of disinfectants these must of necessity continue.

It is universally admitted that mercuric chloride is an efficient disinfectant, but loose statements have been made regarding the value of this efficiency. It has been asserted, e.g., that solutions of 1 in 50,000 and 1 in 100,000 are reliable germicides, whilst nothing whatever is said of the nature of the changes effected, which result in the death of the bacteria concerned.

Tons of HgCl₂ have been used, and are still being used in India for the disinfection of *B. pestis*, with results, alas! only too well known. Apart from exact knowledge of the strengths and methods of use of the solutions employed, it is impossible to arrive at an opinion, other than the broad one, that up to the present, at least, it seems to have been of little practical value.

In common with other salts of heavy metals, HgCl₂ is an active coagulant of albumen, but its energetic powers of coagulation militate at times against its germicidal efficiency. It would seem that, in accordance with the chemical fact that a weak alkaline solution is the best solvent for proteids, the alkaline emulsions must hold a premier place as disinfectants of proteid masses whose interiors contain bacteria, by reason of their larger powers of penetration.

Here it may be pointed out that in using the Rideal-Walker or other test, it is quite possible to obtain an inaccurate impression of the germicidal value of a

disinfectant which is a strong coagulant of albumen, when applied to such infected material as intestinal sloughs in typhoid stools. It is obvious that more thorough disinfection will be obtained when wholly liquid stools are dealt with, than when stools containing solid masses are used. In the former case there is greater opportunity for the disinfectant to come into contact with all the bacilli. Moreover, the loopful removed from a medicated mixture of a fluid stool containing solid masses, for implantation in a culture medium, will contain no such solid mass, and therefore any bacteria that may be found in the centre of such mass are left behind uninjured, whilst the disinfectant receives credit for having killed them all. This is but one of the many features of the complex problem of practical disinfection which require careful study.

The following experiments in the disinfection of spores of anthrax and B. typhosus with HgCl₂, bring to light an inhibitory action exerted by this disinfectant which would appear to account for the many wild statements to be found in the text-books in connection with this body.

Working with the Rideal-Walker method of standardisation, we are unable to assign a carbolic-acid co-efficient to HgCl₂, as phenol (the control disinfectant) does not kill these spores in the time limits of the test.

Tables I. and II. demonstrate the difference in the germicidal powers of HgCl₂ upon anthrax spores, and Tables III. and IV. the difference in these powers upon B. typhosus, according as the inhibitory action is, or is not, eliminated.

Through the conveyance of the medicated spores or organisms to culture broth by a platinum loop, a small quantity of HgCl₂ is introduced into the broth, which exerts the above-mentioned inhibitory action on the organisms, and that this action is merely inhibitory and not disinfectant is seen by the fact that precipitation of Hg as HgS by a drop of H₂S water (saturated solution) previously added to the broth tube (whereby the organisms are rapidly liberated from the influence of HgCl₂) permits the growth of organisms that otherwise would not take place, within the time limits of the experiments. This change has its expression in the lowering of the germicidal powers of HgCl₂, recorded in Tables II. and IV.

TABLE I.
ANTHRAX SPORES EX AGAR.
Room Temperature 15°-18° C.

Sample.	Dilution.	Time culture exposed to action of disinfectant—minutes.						Sub-Cultures in broth.	
		2½	5	7½	10	12½	15	Incub.	Temp.
HgCl ₂	1 in 3000	X						7 days	37°C
	1 ,, 4000	X							
	1 ,, 5000	X	X						
	1 ,, 6000	X	X	X					
	1 ,, 7000	X	X	X	X				

TABLE II.
ANTHRAX SPORES EX AGAR.
Room Temperature 15°-18° C.

Sample.	Dilution.	Time culture exposed to action of disinfectant—minutes.						Sub-Cultures in broth X H ₂ S	
		2½	5	7½	10	12½	15	Incub.	Temp.
HgCl ₂	1 in 40	X						7 days	37°C
	1 ,, 60	X	X						
	1 ,, 80	X	X	X					
	1 ,, 100	X	X	X	X	X			
	1 ,, 120	X	X	X	X	X	X		

1. A growth of anthrax spores on agar was emulsified in 3 cc. of sterile distilled water, and filtered. Five drops of this emulsion mixed with 5 cc. of a 1 in 3,000 mercuric chloride solution for 2½ minutes, showed no life when sub-cultured in broth for seven days. Life appeared, however, in the case of 1 in 4,000 solution applied for 2½ minutes, and in 1 in 5,000 solution applied for 5 minutes, as seen in Table I.

2. The addition of a drop of H₂S water to the broth tubes, prior to their receiving a loopful of medicated spores, requires a stronger solution than 1 in 40 applied

for 2½ minutes, and a stronger solution than 1 in 60 applied for 5 minutes, to completely kill, as seen in Table II.

TABLE III.
B. TYPHOSUS, 24 HOURS' AGAR CULTURE
AT 37° C.

Room Temperature 15°-18° C.

Sample.	Dilution.	Time culture exposed to action of disinfectant—minutes.						Sub-Cultures in broth.	
		2½	5	7½	10	12½	15	Incub.	Temp.
HgCl ₂	1 in 20,000	X	X					7 days	37°C
	1 ,, 40,000	X	X						
	1 ,, 60,000	X	X	X	X				
	1 ,, 80,000	X	X	X	X	X	X		
Phenol	1 ,, 100	X							

Carbolic Acid Co-efficient between 200 and 400.

TABLE IV.
B. TYPHOSUS, 24 HOURS' AGAR CULTURE
AT 37° C.

Room Temperature 15°-18° C.

Sample.	Dilution.	Time culture exposed to action of disinfectant—minutes.						Sub-Cultures in broth—H ₂ S.	
		2½	5	7½	10	12½	15	Incub.	Temp.
HgCl ₂	1 in 2000	X	X					7 days	37°C
	1 ,, 2300	X	X	X					
	1 ,, 2600	X	X	X	X				
	1 ,, 2900	X	X	X	X	X	X		
Phenol	1 ,, 100	X	X						

Carbolic Acid Co-efficient 20.

3. Working under the same conditions with agar cultures of B. typhosus, HgCl₂ was put in competition with pure carbolic acid. Table III. shows that under these conditions it possesses a co-efficient of 200-400.

4. When, however, the medicated mixture is sub-cultured in broth to which a drop of H₂S has been added, the coefficient drops to 20.

The necessity for recognising this factor of inhibition in deriving the carbolic-acid coefficient of HgCl₂ is thus plain

THE MORISON LECTURES ON THE PATHOLOGY OF GENERAL PARALYSIS.

DELIVERED IN THE ROYAL COLLEGE OF PHYSICIANS,
EDINBURGH, ON JANUARY 24TH, 26TH, AND 29TH,
By W. FORD ROBERTSON, M.D., F.R.C.P.ED.

ABSTRACT OF LECTURE I.

DR. FORD ROBERTSON referred at the outset to the prevalence and recent increase of general paralysis in this and other countries. Every year nearly two thousand persons died from this disease in the asylums of England. It was one of the most terrible maladies that could afflict a human being. It was fatal, with rare exceptions, within a few years. Its causation and exact nature, notwithstanding many positive assertions that had been made regarding them, had hitherto been a profound mystery. In the recent literature of the subject there could be traced a growing feeling of scepticism regarding the widespread view that the disease is essentially syphilitic in its origin. After briefly sketching the main facts already known as to the morbid changes that occur in the brain, Dr. Robertson proceeded to give an account of the investigations into the pathology of the disease carried out by his colleagues and himself during the last six years at the laboratory of the Scottish asylums, and at the Royal Edinburgh Asylum, and also independently by Dr. L. C. Bruce at Murthly Asylum. The earlier researches, conducted on the clinical side by Dr. Bruce and on the pathological side by the lecturer, had tended to show that general paralysis is dependent on an active bacterial toxæmia, and that the point of attack is commonly the alimentary tract. In 1902, along with Dr. M'Rae and Dr. Jeffrey, he commenced a bacteriological investigation. A

micro-organism closely resembling the bacillus of diphtheria was found to be specially prominent. It was constantly present in the alimentary or respiratory tracts in cases of general paralysis, and in several instances cultures were obtained from the brain. The lecturer and Dr. M'Rae had since been endeavouring by various methods of research to determine whether this bacillus had any special relationship to general paralysis, and every step forward had been attended with the elucidation of some fresh fact which rendered the hypothesis more probable. They were now able to bring forward evidence to show that general paralysis and the allied disease—*tabes dorsalis*—are as specific in their causation as tuberculosis, typhoid fever, and diphtheria. Histological and experimental evidence had contributed in a considerable measure to the support of this view. They had now succeeded in obtaining the diphtheroid bacillus from the brain in nine cases out of twenty-three, in which cultures were made from this organ; they had also succeeded in detecting the bacilli in microscopic preparations in the fresh blood and cerebro-spinal fluid, as well as in the walls of the cerebral vessels. In these instances the bacilli were rarely capable of staining in the usual way, and this fact has raised the question whether these bacilli were not from time to time gaining access to the circulation, and being rapidly destroyed by phagocytic and lysogenic action. This hypothesis had been experimentally put to the test by investigating the action of the living blood upon pure cultures of diphtheroid bacilli isolated from cases of general paralysis. The results of this inquiry had served to throw light upon the problem of the pathogenesis of the disease.

ABSTRACT OF LECTURE II.

Dr. Robertson said that he wished to deal chiefly with the results of an experimental inquiry that Dr. M'Rae and he had made into the action of the living blood and blood serum upon pure cultures of diphtheroid bacilli isolated from cases of general paralysis. The bacillus with which they had worked was one which in respect of the morphological characters, staining reactions and power to form acid in glucose broth, closely resembled the Klebs Löffler bacillus. It had been laid down by high authorities that an organism differing from the diphtheria bacillus solely in want of virulence must be regarded as merely a diphtheria bacillus in an attenuated condition, and should be spoken of as such. In previous papers the organism had therefore been provisionally regarded as an attenuated form of Klebs-Löffler bacillus. Whether it was really of this nature or not was an open question. Their more recent observation strongly inclined them to the view that it was a special organism. Having referred to the remarkable polymorphism of this bacillus the lecturer considered especially its thread form. The organism had been observed to invade the tissues in this form in several general paralytics; it had also been observed invading in four rats fed or injected with cultures of the bacillus. The bacillus when first isolated often showed a strong tendency to form threads. They had endeavoured to ascertain how the organism could be made to assume this special character, and they had succeeded in obtaining a filamentous growth by cultivating it for several days at 41° C. upon blood films. It was therefore probable that invasion by the thread form occurred in cases in which there had been a sustained high temperature on several days before death. One of the points they had specially studied was the phagocytic action of the leucocytes upon the bacillus. They had used a technique of their own. Two actions required to be studied, namely, the power of the leucocytes (in the natural serum) to take up the bacilli, and the power of the leucocytes to dissolve the bacilli when engulfed. No constant alteration could be detected in the power of taking up in the general paralytic's blood. On the other hand, the power of dissolving the bacilli when taken up had in most cases been distinctly greater on the part of the leucocytes of the general paralytic

than on that of the leucocytes of the control. Within the first three hours of incubation, at least, the lysogenic section was entirely intra-corpuseular. Having studied the appearances presented by the dissolving organisms in the experimental films, they endeavoured to ascertain if bodies having a similar appearance could be found in the fluid and tissues of the general paralytic. Every case studied with this object had given the same affirmative answer. Diphtheroid bacilli, more or less altered by lysogenic action, were present in great numbers in the catarrhal pneumonia foci that occurred in most general paralytics dying in congestive attacks. They could also be detected in the adventitial spaces of the inflamed cerebral vessels and in the meshes of the pia arachnoid. Further, they could be observed in films made from the blood of the living paralytic, especially if the patient was suffering from a congestive attack. They could also be detected in the centrifuge deposit from the cerebro-spinal fluid, obtained by lumbar puncture. Lastly, they were often present in large numbers in the centrifuge deposit from the urine, especially during a congestive attack. This experimental study had suggested to them that failure to obtain cultures from the blood and cerebro-spinal fluid depended upon the fact that most of the bacilli were dead, and that the few living ones that were occasionally present were killed in consequence of the continued action of the phagocytic cells. They had therefore tried various measures with a view to preventing the continuation of this bactericidal action, the simplest of which was to allow the tubes to stand in the cold for twenty-four hours before incubating them. By adopting this plan, or slight modifications of it, they had succeeded in getting pure growths from the blood in four cases (three of the patients being in congestive attacks) and from the cerebro-spinal fluid in two. The growths were first generally extremely feeble, but the organisms could be invigorated by being sub-cultured upon blood films. A search had been made for a specific action of the blood of the general paralytic upon these bacilli. The most distinctive reaction they had obtained was that which concerned the power of the leucocytes to dissolve the bacilli. They had estimated the percentage of altered bacilli in the leucocytes after three hours' incubation. This gave what they called the intra-corpuseular bacteriolytic index. As far as their observations went it was as a rule higher in the general paralytic's blood than in control bloods. It seemed, however, probable that more direct methods of bacteriological diagnosis would become available.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL, KINGSLAND ROAD, N.E.

Occasional Hæmaturia.

By LEONARD WILLIAMS, M.D., M.R.C.P.

In demonstrating the case, Dr. Williams said: This man, whose age is 70 (he looks little more than 60), complains of occasional hæmaturia. The amount of blood, when it comes, is considerable; the urine is thoroughly red, it is not merely smoky or tinged; it is characteristically and unmistakably sanguineous. The patient has a sort of premonition of its coming. He does not know why, but he knows he is going to pass blood. When the blood comes it is not intimately mixed with the urine from the outset. Clear urine comes first, and the appearance of the blood is delayed until the *coup de piston*, as the French term it. This has been going on at intervals, sometimes very considerable intervals, for three years. He has been to other hospitals, but unlike many patients he is not able to give us even a garbled version of the judgments which have been there passed upon him. He nevertheless comes with a diagnosis with which he has been favoured by his club doctor. This diagnosis is that of granular kidney, and although I believe that this is not a correct view of his condition it is a view which

is far from being discreditable to the person who held it, inasmuch as it shows that he remembered a fact which we are all of us much too liable to forget, namely, that granular kidney is one of the most powerful producers of hæmorrhage in all parts, even in most unlikely parts, of the body. That the doctor, in remembering this fact, failed to see it in its proper perspective with relation to some others only proves that, in common with the rest of us, he is liable to make mistakes. The only people who are never guilty of diagnostic errors are the newly-qualified. Let us remember, then, in connection with this man that granular kidneys may give rise to hæmorrhages anywhere, so that when we meet with epistaxis, with bleeding from the rectum, with hæmoptysis, with hæmatemesis, we may recall the fact that renal cirrhosis is not an impossible, nor, indeed, an improbable cause. Hæmorrhage into the brain, causing apoplexy, to be followed by a hemiplegia, is the classical instance of one of the dangers of interstitial nephritis, but we must be careful not to let our imagination stop short of this picture; we must include in our survey any bleeding, however slight and unimportant it may for the moment appear to be. I have said that I do not believe this man to be the subject of renal cirrhosis, and my opinion is based upon the fact that apart from the hæmorrhage (the *coup de piston* character of which is suggestive rather of bladder trouble), I can find no evidence of kidney disease. The absence of albumin in the urine is no criterion. If it is present it constitutes valuable confirmatory evidence; but the man who cannot determine the presence of interstitial nephritis without this aid is, diagnostically, naked indeed. Interstitial nephritis, as you know, is associated with high blood pressure; that is why it is apt to give rise to hæmorrhages. I say "associated" with high blood pressure, because I want to guard you if I can from the too common error of believing that granular kidney *causes* the high blood pressure. Frequently it is the high blood pressure which causes the fibrosis in the kidney. More frequently still, perhaps, they are both due to a common cause. Nevertheless, it is a fact that where there is renal cirrhosis there also will high blood pressure be found. We have not yet an instrument for measuring blood pressure here, which is a misfortune, because even highly-educated fingers are liable to err in estimating slight degrees. But if this man had had an interstitial nephritis for over three years, there would have been no question of slight degrees. The hypertension of his pulse would have been obvious to the least educated of naked fingers; he would have had an enlarged left ventricle, displacing his apex beat to the left of the nipple line, and he would have had a loud ringing second sound at the aortic cartilage, telling of the strain to which the semi-lunar valves were subjected at each diastole. He has none of these, and in their very definite absence I feel justified in asserting that whatever else is the matter with him he is not the subject of chronic interstitial nephritis. To say what is the matter with him is, however, not an easy task. I have urged him to come into the hospital, and allow the surgeons to explore his bladder, which I assume to be the source of his hæmorrhage, but he remains obdurate to all my representations. He says that at the age of 70 he prefers to bear the ills he has rather than fly to others that he knows not of. And, having regard to all the circumstances, I cannot help thinking he is right.

OPERATING THEATRES.

FRENCH HOSPITAL.

INTESTINAL OBSTRUCTION FOLLOWING GONORRHOËAL PYO-SALPINX.—MR. EDMUND OWEN operated on a female, æt. 20, who had been admitted suffering from acute gonorrhœa of a fortnight's duration. The girl complained of severe abdominal pain chiefly in the hypogastric and left inguinal regions. A tumour could be felt on deep palpation in these regions rising out of the

pelvis. Examination by the vagina showed that the uterus was fixed by a mass of exudation above the left fornix and in Douglas's pouch. The left tube was evidently involved in this mass and formed a tumour about the size of an orange which could be felt bimanually. No fluctuation could be detected. The patient had a temperature and an aspect of a septic character. The tumour in the left inguinal region increased in size and tenderness; fluctuation could soon be elicited. On performing abdominal section, a large quantity of ill-smelling pus escaped from the abscess, which had extended into the abdominal cavity, but was limited by adhesions. The patient did very well for a fortnight, the abscess cavity having practically healed, but she then developed signs of acute intestinal obstruction. A second operation having been decided upon, an incision was made in the middle line. The intestines were found to be closely matted together and they were covered with masses of lymph. A coil of small intestine, greatly distended, was found firmly glued to the bottom of Douglas's pouch; this was freed and various adhesions were broken down, the obstruction being thus released. An ounce of a strong solution of magnesium sulphate was injected into the bowel by an exploring syringe. The right Fallopian tube was examined and found to be healthy.

Mr. Owen said that, considering the small size of the French Hospital, it was quite remarkable for the number of cases of pyo-salpinx which came under the care of his colleagues, Dr. Sunderland and Mr. Clayton-Greene, and himself for operation, and that few operations afforded greater interest or more interesting complications. Acute intestinal obstruction, he pointed out, was by no means an uncommon sequel of such operations, and, considering the extent of the area of inflammation which must inevitably be left after such operations, it was almost a matter of surprise that this complication did not more often occur. When vomiting and abdominal distension, together with a quickening of the pulse and a distressed appearance set in after an apparently successful operation for pyo-salpinx, he was of opinion that abdominal exploration should not be unduly delayed.

The woman made an uninterrupted recovery from the operation, and left the hospital, cured, six weeks after the second operation.

TOTTENHAM HOSPITAL.

HYSTERECTOMY FOR FIBROSIS, COMBINED WITH OVARICTOMY.—DR. ARTHUR GILES operated on a married woman, æt. 47, who had been admitted on account of persistent hæmorrhage, and an abdominal tumour. She had been seen in the out-patient department where she was regarded as suffering from uterine fibro-myoma. On examination, a mass was felt which could not be distinguished from the uterus; the outline was irregular, and the diagnosis of uterine myoma was confirmed. At the operation, when the abdomen was opened the tumour was found to consist of uterus alone, but of uterus and ovarian cyst, the latter originating on the right side. A complete extirpation of uterus and tumour was effected, the hysterectomy being of the type known as supra-vaginal. The operation presented no special complications, and the abdomen was closed in the usual way. Dr. Giles said that the question of diagnosis was a very interesting one in this case. A history of long continued hæmorrhage, associated with a large tumour apparently uterine, and of firm consistence would lead one to a diagnosis of uterine myoma every time, although such a diagnosis would turn out incorrect in a small

percentage of cases. He did not think there was any method by which one could avoid the possibility of error in such cases, the symptoms were identical, and the physical signs hardly distinguishable. In a case in which the tumour was ovarian the uterus would be of only normal length, but this might be true also of a case in which uterine myomata were sub-peritoneal and pedunculated. An ovarian cyst would usually give the sensation of a fluid tumour in contra-distinction of the hardness of a fibro-myoma, but a myoma might be partly softened suggesting, an ovarian cyst, or, on the contrary, an ovarian tumour might present a firm

consistence as in the case just operated on. As a rule, an ovarian cyst was not associated with hæmorrhage; when this symptom was present one of several rare conditions might be found, namely, ovarian carcinoma, a simple ovarian cyst combined with uterine polypus or ovarian cyst complicated by fibrosis. He anticipated that the uterus in the present case would prove to be the seat of fibrosis; in any case, with such a history as this patient presented a simple ovariectomy would practically be of no use, and for this reason he did the hysterectomy at the same time. The patient made an uninterrupted recovery.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEBRUARY 9th, 1906.
The President, Mr. CLUTTON, in the Chair.

Mr. B. G. A. MOYNIHAN read a paper on
THE SURGICAL TREATMENT OF CARCINOMA OF THE
STOMACH,

based on the records of 59 operations for this condition during the last eight years. The operations performed were gastro-enterostomy, 35 cases with 5 deaths; gastrectomy, 10 cases with 3 deaths; gastrostomy, 5 cases with no deaths; jejunostomy, 3 cases with no deaths; and exploratory laparotomy, 6 cases with 1 death. Dealing first with gastro-enterostomy, he considered that this operation was indicated in cases with an irremovable growth causing pyloric obstruction; where there was no obstruction to the outlet of the stomach the operation did not give relief commensurate with its risks. Mr. Moynihan had found that, in suitable cases, gastro-enterostomy prolonged the patients' lives and allowed them to spend their last weeks or months in tolerable comfort. With regard to gastrectomy he was convinced that modern improvements in technique had rendered the radical operation applicable to a wider range of cases than formerly, not only as a means of complete cure, but as an operation to be undertaken deliberately in preference to gastro-enterostomy as a palliative measure. In 5 cases where the growth caused obstruction at the cardiac end of the stomach Mr. Moynihan performed gastrostomy; adopting Senn's method in 4 cases, Frank's method in 1. Jejunostomy is adapted to those cases in which gastro-enterostomy is impossible by reason of the extensive involvement of the stomach, and where gastrectomy is contra-indicated by the presence of secondary deposits. It is chiefly of importance when the prolongation of life, for even a brief time, is of great moment. He deprecated the prevalent opinion that an exploratory laparotomy "to confirm the diagnosis" is devoid of risk. Cases where the diagnosis is in need of operative confirmation are those where close scrutiny and handling of the parts is necessary; where the condition can be recognised by merely inserting a finger within the abdomen the clinical diagnosis as a rule requires no corroboration. Mr. Moynihan drew attention to the frequent incidence of cancer at the pyloric end of the stomach, and to the regular invasion of the curvatures, both these facts being well brought out in his series. Between the pyloric and pre-pyloric forms of growth he believed that a diagnosis was often possible by careful attention to the onward march of symptoms. As bearing on the frequency of malignant transformation of simple ulcer, he has found that out of 39 cases of carcinoma of the stomach where attention was directed to this point 24 gave a previous history indicative of gastric ulcer. He noted the fact that both ulcer and cancer affect the same portion of the stomach wall, and was inclined to assume that a chronic inflammatory condition was the cancerous precursor as frequently here as elsewhere in the body. He believed that the

discouraging results of the surgical treatment of gastric carcinoma were due to the fact that the insidious onset of the disease rendered early diagnosis far from easy, but he hoped that in the future by a careful application of clinical methods and a wider recognition of early symptoms, the surgeon would be more often called upon to explore in order to *make* a diagnosis rather than to *confirm* one arrived at by waiting until too late.

Mr. CLUTTON commented on the large number of these cases seen by the Leeds surgeons.

Mr. MAYO ROBSON pleaded for earlier consultations between physicians and surgeons in stomach complaints. He had operated on 120 cases of cancer of the stomach, over 80 having been during the past ten years, and was now preparing an analysis of them. He was impressed with the importance of earlier diagnosis in these cases, and was in favour of exploratory laparotomy even when the diagnosis was obscure, if medical treatment was of no avail in a few weeks. There was very little risk in this operation provided it was done early enough. He referred to cases of chronic inflammatory thickening, which, even at the operation, were diagnosed as cancer, but which got quite well after gastro-enterostomy. He considered that ulcer was a most important factor in the causation of gastric cancer.

Mr. LEONARD BIDWELL recommended not performing a radical operation, when possible, at the first operation, but rather to do gastro-enterostomy as a routine and then a partial gastrectomy a fortnight later. He had only lost one case out of five treated thus. As to gastrostomy, he always found that the use of Symonds' tubes gave greater benefit.

Dr. DE HAVILLAND HALL supported Mr. Robson in his claim for early surgical consultation.

Dr. FAWCETT was doubtful about the alleged importance of gastric ulcer as a precursor to cancer. It was not supported by the analysis of the Guy's records. What did Mr. Moynihan consider sufficient evidence of ulcer?

Mr. JAMES BERRY asked Mr. Moynihan whether he did a gastro-enterostomy prior to gastrectomy, whether he performed entero-anastomosis at the same time as the former operation, and whether he found clamps essential.

Surgeon-General LONGHURST was glad to hear that cancer was a local disease and not a general one. He emphasised the importance of calling surgeons in to stomach cases early.

Mr. F. C. EVE asked Mr. Moynihan what his practice was when glands were found in the pancreas, for such glands were frequently inflammatory not malignant and so might exercise undue deterrence as regards the performance of radical operation. He assented in the observation that pre-pyloric cancer sometimes produces the same clinical picture as pyloric cancer, and also in the possibility of chronic inflammatory masses being mistaken for cancer.

Mr. MAKINS queried the value claimed for gastro-enterostomy. His patients rarely lived for over a year

and were not always in perfect comfort. The advantages of the operation were difficult to estimate.

Mr. MOYNIHAM, in reply, said that it would be a good thing if the practice that held in the North of sending stomach cases to physicians only if a surgeon considered operation inadvisable were introduced into London. He always removed the growth straight away whenever possible, without a preliminary gastro-enterostomy. As to the question of ulcer in the ætiology of cancer, in over 50 per cent. of his cases ulcer had been diagnosed by the medical attendant years before the cancerous condition developed. In his opinion chronic dyspepsia was usually due to ulcer, and vomiting was quite rare in this condition, hæmatemesis being rarer still. He regarded hospital records as quite worthless unless the point under discussion had been specially looked for. He never did entero-anastomosis, as in his operation this was quite impossible, the upper end of the opening being over an inch below the duodenal jejunal flexure. He always used clamps and was convinced of the saving in time effected by them. He removed all glands whether they were obviously cancerous or not.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FEBRUARY 7TH, 1906.

Dr. J. O. AFFLECK, President, in the Chair.

Mr. J. M. COTTERILL showed (1) a fibro-sarcoma of the eighth nerve, removed from the cerebello-pontine angle along with a large part of the cerebellum, excised for the purpose of exposing the growth. (2) Specimens of enlarged prostate removed by suprapubic prostatictomy.

Dr. W. ALLAN JAMIESON exhibited a patient with an extra-genital chancre.

Dr. NORMAN WALKER showed a case of melanoma, probably an early instance of scroderma pigmentosum.

Dr. F. B. BOYD read a paper on

RECTAL FEEDING,

of which the following is an abstract:—

Our present knowledge of the exact value of rectal feeding is indefinite and conflicting. The following observations have been undertaken, with the assistance of Miss Robertson, in order to elucidate certain points as to the absorption of food substances by the bowel. The severe cases, in which sufficiently prolonged investigations could be carried out to warrant these deductions being drawn, representing only the most favourable cases, *i.e.*, those which tolerated rectal feeding well. They form only a few of the many observations which were attempted but broke down either on account of the gastric disturbance which the rectal feeding caused, or because menstruation set in soon after the injections were begun, and thus rendered impossible accurate estimations of the nitrogen balance, &c. Before rectal feeding was begun an aperient, mixed with charcoal was administered, and after the bowels had been freely moved and charcoal was being passed in the fæces, the observations were commenced. After a cleansing enema had been given, nutrient injections were administered, and the total nitrogen excretion, the fat, and the carbohydrates, contained in the fæces were estimated daily. The calorific value of the food was known, as well as its nitrogen, fat, and carbohydrate content. The patient's weight was ascertained daily. The food was predigested; it consisted of milk, eggs, and dextrose, and was prepared in bulk, so as to be of uniform composition, being preserved by the addition of a little chloroform. It is agreed that at rest a person requires to be supplied with food representing about 2,000 calories per 24 hours; the quantity of proteid required is usually stated at from 80 to 100 grams, but recently Chettenden has maintained that this is excessive, and that 40 grams is sufficient. The first point to be considered is the *absorption and metabolism of proteid* given by the bowel. The best results attained in these observations were the absorption of 10 and 13 grams of proteid;

in the majority of Dr. Boyd's cases the figures were much lower. The amount of proteid taken up from the injected food seems to bear no sort of relationship to the total quantity of proteid contained in it. The calorific value of the proteid in these two test cases was 43 and 56 respectively. Taking an average of all the cases, the absorption of nitrogen was only 0.297 grams per kilo of body weight, a figure which is very considerably less than that given by German investigators, who have found that the amount is as high as 1 per kilo. In all his cases there was a negative nitrogenous balance of about 4 grams on the average, this showing that the patients were excreting nitrogen at the expense of their tissues. *Absorption of Fats*: It is advisable to use an animal fat, and that selected was yolk of egg. Some investigators have stated that not more than about 10 grams of fat can be absorbed from the bowel daily in rectal feeding, but these observations show that as much as 45 grams, or nearly 43 per cent. of the total fat in the injections may be taken up. The amount absorbed is directly proportionate to the quantity contained in the injections. *Absorption of Sugars*: It is difficult to determine this, and the objection has been raised that when the method adopted is that of estimating the amount introduced, and the amount excreted in the fæces, and taking the difference between these as representing the quantity absorbed by the bowel, no account is taken of the fact that much of the sugar may be broken down to lactic acid, &c., by putrefactors and other fermentations in the bowel, and hence the diminished amount which is credited to absorption is really partly due to decomposition. This point had been attended to, and check experiments made, which showed that fermentation did not diminish the amount of sugar by more than 1 per cent. It was found that practically all the sugar introduced in a nutrient enema is absorbed. Sugar is very often said to be irritating to the rectum, but this is due probably to impure sugar containing traces of sulphuric acid, &c., being employed. To obviate this difficulty he had always employed pure dextrose. As the result of his observations the question arises, How far is rectal alimentation of real value? In the cases of which tables were shown, the maximum calorific value of the food absorbed was about 500 calories, never more than 600, about one-fourth of what was actually needed—and this in persons who tolerated enemata remarkably well. He had tried Leube's pancreatic extract in nutrient enemata, and had found it of use. It causes irritation, and is extremely objectionable from the amount of intestinal putrefaction which results. Auto-intoxication is produced, and the evacuations become extremely offensive. The practical deductions from his observations are that nutrient enemata cannot be trusted to supply sufficient nutriment for the needs of the body; moreover, in many acute gastric cases it is better to trust to saline injections alone, because nutrients, as has been proved, reflexly excite gastric secretion and may cause vomiting. In giving nutrient enemata it is commonly stated that the quantity should not exceed 4 to 6 ounces. Probably it is better to give larger amounts, up to 10 ounces. Nutrients should be pre-digested, and should consist of milk, eggs, dextrose, and a pinch of salt. They should be introduced gradually through a funnel and catheter, rather than by a syringe.

Dr. NOEL PATON congratulated Dr. Boyd on his very laborious investigations. He asked whether account had been taken of the output of nitrogen in the fæces, which was due to intestinal secretion, epithelium, &c.?

Dr. RITCHIE thought that Dr. Boyd was unduly pessimistic as to the value of nutrient enemata; even if only a fourth of the necessary calories could be introduced, it was better than nothing.

Dr. RUSSELL also agreed that what Dr. Boyd had said was not of such a nature as to discourage them in using rectal alimentation. He hoped Dr. Boyd would continue his investigations with the view of discovering what particular form of nourishment was best absorbed.

He had for some time had the impression that pancreaticised foods were apt to intensify intestinal putrefaction.

Dr. AFFLECK spoke of the great comfort which patients derived from nutrient enemata, which he considered a valuable aid to treating acute gastric disorders.

Dr. Church and Mr. Cathcart, and Dr. Gulland also spoke.

In his reply Dr. BOYD said that he had not meant to decry nutrient enemata altogether, but merely to point out their limitations. For instance, he regarded it as impossible to restore the nutrition of a patient, say with pyloric stenosis, prior to operation, in this way. All the most nutrient enemata could do was to delay loss of weight. In acute gastric cases a great deal of the comfort derived from enemata was due to the absorption of water. After a hæmorrhage, for example, the tissues cried for fluid, and saline injections alone might increase the patient's weight. Other carbohydrates than dextrose might be used; the object in choosing this particular substance was because it could readily be accurately estimated.

Mr. C. W. CATHCART read a paper on
BIER'S METHOD OF TREATING ACUTE INFLAMMATION
BY PASSIVE CONGESTION.

Surgery, he said, could tell them how to destroy organisms outside the body, and how to prevent their entrance into wounds, but when once a patient came to the surgeon already infected, antiseptic methods were of comparatively little value in curing suppuration. When pus is forming, the best agents in limiting its spread are the tissue cells and fluids, and surgery can do nothing more than assist these in their conflict with the organisms. For such conditions as whitlows, osteomyelitis, suppuration in joints, tendon sheaths, or cellular tissues, and infected wounds, which the surgeon is powerless to prevent, a curative method is much needed, and it seems as though Bier's treatment by passive congestion, though its *modus operandi* is unknown, may supply the want. It is not claimed that the method is infallible, but only that in many cases it will prevent or limit suppuration. Bier looks on inflammation as a curative process, and the practical outcome of the theory is to favour the condition of the parts which inflammation produces—redness, congestion, and œdema with serous effusion—by the application of an elastic Martin's bandage to the proximal part of the limb. Bier has employed this since 1893, but it has only recently been introduced into this country. A considerable amount of experience is required as to the degree of pressure which may be applied; the limb should become red and angry-looking, there should be œdema, and a good deal of serous effusion. The bandage is allowed to remain in position for as much as 20 hours daily in these acute cases. One of the first results is relief of pain, which is often very marked and comes on within a few minutes of the application of the bandage; this is a practical test as to whether or not the bandage is correctly applied. With this the patient's general condition improves, and his pulse and temperature fall, unless there is already systemic infection. The more acute the local inflammation, the easier is it to produce œdema and congestion by the ligature. No dressing save a light porous one should be applied to the part. After progress has once begun, it usually continues, and then the periods of congestion may be shortened. When a definite abscess is present after the treatment has been continued for a day or so, the pus should be evacuated, but it is only necessary to make a small incision, and no drain is required. Before detailing his own results, Mr. Cathcart quoted a number of cases from Bier's writings to illustrate the scope of the treatment. Bier had successfully employed passive congestion to control abscess formation in pyæmia secondary to scirrhus of the breast; by it, though somewhat rarely, an acute abscess could be converted into a cold abscess, and in some cases could be made to disappear altogether. The method of treatment seemed peculiarly beneficial in acutely

inflamed joints, particularly in gonorrhœal infections, and also in suppurative arthritis. After the elastic ligature was applied the joint was not immobilised, but early passive movement was begun as soon as the anæsthetic effect of the congestion was manifest. Thus a cure was obtained even in the most severe cases. If sinuses had already formed they were squeezed so as to empty them, but were not drained. In that most trying form of suppuration, namely, infection of the tendon sheaths, the method also found a useful field of work. Cases of whitlow did very well under it if it was begun early; and if the tendon sheaths were already invaded, passive congestion was only palliative. In acute osteomyelitis nearly half of the cases recovered without necrosis, in the rest there was only a small sequestrum. Bier's method could be applied to all forms of acute inflammation, even such as were not due to micro-organisms, e.g., bites of poisonous insects. It could also be applied to almost every part of the body. Bier did not hesitate to apply an elastic ligature round the neck, if necessary; while for sites where proximal ligatures were impossible, suction cups of various shapes and sizes had been devised. Mr. Cathcart's personal experience of Bier's method had been surprisingly satisfactory, and he described as illustrative cases (1) acute suppuration in the tendon sheath of the little finger, causing gangrene of the finger, and extending into the forearm; (2) cellulitis of the hand; (3) gonorrhœal synovitis; (4) gummata of the tibia in congenital syphilis; (5) cellulitis of leg; (6) septic wound of the foot, which was so inflamed as to make moist gangrene appear imminent. In all these the results had been good; the relief of pain is great, and is induced so rapidly that the action resembles that of a general anæsthetic. The temperature is lowered, from diminished absorption of toxins. The rationale of the treatment is not clear; it seems that the increase in the serum in the part has something to do with the results; at least, Bier always likes to see a large serous effusion. It was possible that the serum antagonised the organisms directly, or that it simply diluted the ptomaines, or that it actually neutralised the ptomaines. In this connection it was of interest to note that other measures directed against inflammation, and which were undoubtedly beneficial, must act in almost the opposite way to Bier's method—for instance, free incision and the application of cold; again, the ligature of a main vessel undoubtedly sometimes checked an inflammatory process. On the other hand, poulticing acted to some extent like Bier's method, and that surgeon thought it was less objectionable than was usually taught.

Mr. GEORGE BERRY said that even in ophthalmology a method analogous to the passive congestion treatment had been introduced—the use of dionin in inflammatory conditions of the eye to produce œdema locally.

Mr. CARMICHAEL said that Bier laid considerable stress on the proper selection of cases, and that he emphasised two points in carrying out the passive congestion treatment: (1) *The bandage must cause no discomfort*, and (2) *it must never make the limb cold*, particularly in tubercular cases.

Mr. STRUTHERS also described some of the results he had witnessed at Bier's clinic, and gave an account of his own experience, which was in the main favourable in out-patient work.

Mr. Thomson and Mr. Stiles also discussed the paper.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD FRIDAY, JAN. 26TH, 1906.

The President, Mr. E. H. TAYLOR, in the Chair.

Mr. H. M. JOHNSTON gave a communication on "Abnormalities of the Carpus in Man and their Morphological Significance." He gave a short account of the structure of the carpus in some of the lower forms of

vertebrates and described two cases of supernumerary carpal bones, and exhibited them to the Section. The specimens showed instances of accessory bones attached to the lunar, and corresponding to the epilunar and hypolunar of Pfitzner. In addition, the specimens also showed a divided scaphoid bone and a marked prominence on the dorsal aspect of the hand, formed by a process of the os magnum articulated with the styloid process of the third metacarpal. The subject was illustrated by diagrams and lantern slides.

Dr. T. G. MOORHEAD asked what stress Mr. Johnston laid on the fact that the tables he exhibited indicated that these abnormalities were found more frequently at a later age than at an earlier? He suggested the possibility of the outgrowths being of rheumatic origin and thought the ossicles should be cut across to see if they were of this nature, or were really cancellous bones. He thought also the condition of the scaphoid might be due to an old ununited fracture. He asked if the X-rays had been used in the investigation.

Prof. DIXON remarked that unless specimens, such as those exhibited, had been prepared by the investigator himself, one could not be certain regarding the position or even of the presence of the minute ossicles described by Pfitzner. He believed that many such ossicles were congenital.

Professor FRASER was inclined to agree with Dr. Moorhead and found it difficult to imagine the specimens were of congenital origin.

Mr. JOHNSTON, in replying, said he would be glad to try the transmissibility of the specimens to X-rays.

The PRESIDENT made some observations on Types of Stomach in Man, illustrated by specimens. He pointed out the surgical importance of recognising the existence of such types as those described by His.

Professor FRASER mentioned a case in which half the stomach was in the thoracic cavity and could be pushed in and out of it with the greatest ease. Also another case in which there was a large pocket, larger than the ordinary duodeno-jejunal pouch, which was completely isolated and into which the stomach could be easily pushed.

Professor DIXON referred to the advances in our knowledge of the form of the human stomach, which were due to the work of the late Professor Birmingham, and he also drew attention to the fact that the occasional tubular form of the organ had been recognised by the older writers.

Professor FRASER doubted if there were any practical value in describing the particular form of any hollow organ where the extremes of contraction and dilatation were so great, and the forms and positions varied so much.

Dr. MOORHEAD agreed that there was little practical importance attached to the shape of the hollow viscera.

The PRESIDENT, replying, agreed that the shape of the stomach was extremely variable.

Professor A. F. DIXON exhibited a series of skulls which gave indications of the presence of an occipital vertebra. The significance of the various markings around the foramen magnum was mentioned, and it was suggested that the body of the occipital vertebra was perhaps to be sought for in the little ossicle normally developed at the apex of the odontoid process of the axis vertebra. The relatively early appearance of this ossicle, and its ossification, sometimes, at all events from two centres, seems to favour this idea, and to distinguish the little bone from the vertebral epiphyseal plates with which it is usually included. Further, the fact that the anterior end of the notochord at first lies dorsal to, and is not included in, the cartilaginous basi-occipital perhaps justifies one in not seeking for the body of the occipital vertebra in the occipital bone.

Professor FRASER made the following communication on "the relations of the pneumogastric and other nerve fibres to the persistent arterial arches", which he illustrated on the board, basing his remarks mainly on what could be easily dissected on the left side of the human subject. The superior laryngeal represents the nerve which passes to the larynx between the

internal carotid and the early dorsal aorta, the latter disappears between the carotid and aortic or fourth arterial arch and so lets the nerve free. Should the early connection persist as a cord, the nerve would be found at the junction formed between it and the internal carotid artery, just as the recurrent or inferior laryngeal nerve is always found looping round the junction of the ligamentum arteriosum with the dorsal aorta. Between the internal carotid and the ligamentum arteriosum, which latter represents the sixth arterial arch, there are two arterial arches one of which, the aortic, has always a complete loop of nerve fibres around it formed mainly by the upper cardiac branches of the vagus, that of the left side passing in front of the arch to join its neighbour of the right side behind the arch. The primitive fifth arterial arch disappears, but there is clear evidence of a second loop of nerve fibres round the aortic arch coming chiefly from the last cervical and first dorsal ganglia of the sympathetic, those from the left side being mainly in front and joining those from the right side behind. As I am only dealing with the persistent arches I may leave this loop out of consideration for the present. In addition to those enumerated—viz., superior laryngeal round the internal carotid arch, the cardiac branch loop round the aortic arch, the evidence of a second loop round the aorta, which may represent that of the lost fifth arterial arch, the recurrent laryngeal round the sixth arterial arch, I invariably find another loop formed from the vagus, passing round the front aspect of the functional pulmonary artery (on the left side) to join the nerves behind, this loop is quite clear of the branches running to the lung root, and points suggestively to the Gill cleft origin of the lung.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

CLINICAL EVENING, THURSDAY, FEBRUARY 8TH, 1906.
CHARLES OLDHAM, F.R.C.S., Vice-President, in the Chair.

MESSRS. ARNOLD LAWSON and GEORGE COATS showed preparations from a case of

CONGENITAL ANTERIOR STAPHYLOMA previously brought before the Society by Mr. Lawson. The eye had spontaneously ruptured six weeks later. The central portion of the cornea was thinned and had a cicatricial appearance. The cornea was perforated with a knuckle of iris caught in it. The lens capsule and iris were adherent to the back of the cornea. Owing to stretching the ciliary processes, pars plana, ora serrata, and anterior part of the choroid were carried forwards with the cornea. Owing to the firmer attachment of the ciliary body to the sclera, this had been left in its normal position. Thus the ciliary processes were further forwards than the termination of Descemet's membrane, and the ora serrata was actually in front of the ciliary muscle. Only one other case of the kind had been described, also in a similar case to this one. The reason of this displacement was due to the fact that in fetal life the inner layers of the uvea were less intimately connected with the outer than is the case after birth and the same occurs in many of the lower animals especially in birds. The staphyloma in this case was believed to be due for certain to intrauterine inflammation and perforation of the cornea.

Mr. HOLMES SPICER showed a patient, *æt.* 48, who had always been short-sighted. The left eye had been blind ever since an injury he had received 30 years ago, and the right eye failed in 1901, and now had total posterior synechia and no P.L. The left eye had a corneal opacity and tremulous iris, the lens was tilted and lightly dislocated backwards, it was quite opaque and there was no fundus reflex. The vision was P.L., and the projection was good. On March 3rd, 1903, a needle was introduced behind the ciliary body, and the lens was pushed backwards. Sight was at once obtained, and it had since improved

so that he was now able to see 6-60. There was a large area of myopic atrophy of the choroid about the disc, and the shrunken lens was visible at the bottom of the vitreous.

Mr. SPICER also showed a case of SUPERFICIAL PUNCTATE DEPOSIT ON THE CORNEA. The patient was a girl, *æt.* 16, whose right eye was attacked with interstitial keratitis in 1897. She became deaf in 1902, and she had an attack of interstitial keratitis in the left eye in 1905. The latter was severe and led to much opacity, and to the development of salmon patches in two places, and a deposit of keratitis punctata at the back of the cornea. The left cornea had cleared considerably; there was some deep opacity near the centre, and numerous small brown or dirty white dots exactly like keratitis punctata, but they were evidently close to the surface, and in front of the old interstitial opacity.

Mr. LUDFORD COOPER showed a girl, *æt.* 11, suffering from

ELEPHANTIASIS NEUROMATOSIS.

There was much deformity of the right upper eyelid and temporal region. The lid was pendulous, and all its structures were greatly hypertrophied. The lid was also considerably everted. The patient was unable to lift it, and it could with difficulty be raised so that the small shrunken globe beneath it could be seen. The lens was opaque and the tension was normal. The outer and lower portions of the frontal bone, and of the squamous portion of the temporal bone were much more prominent on the affected side. The condition was congenital, and was slowly increasing.

Mr. E. E. HENDERSON showed a woman *æt.* 29, who had a growth on the upper palpebral conjunctiva. For several weeks she had noticed something movable beneath her upper lid, and for three days it had protruded. An oval mass was found about 2.5 cm. long and 1 cm. broad. Its surface was smooth and vascular, and was attached to the fornix by a strip of conjunctiva containing vessels. It was thought to be tubercular.

Mr. SYDNEY STEPHENSON showed a boy, *æt.* 9, who had two detachments of the retina in one eye, one above and the other below. The tension was increased, and the vision was bare P.L. Transillumination showed that light passed readily through both detachments. The other eye was myopic, with some vitreous opacities. There was an obscure history of injury, and a doubtful history of tubercle in the family. The question was one of diagnosis, though it was considered to be of a tubercular nature by Mr. Stephenson.

Mr. H. S. MORTON and Mr. LAWSON showed interesting cases.

Mr. TREACHER COLLINS showed two cases of CONGENITAL COLOBOMA OF THE IRIS WITH A BRIDGE. In the first case there was a bridge of pigmented iris tissue about 1 m.m. in breadth, stretching across the space formed by the pupil and the coloboma. It was situated a little below the level of the margin of the pupil, which was pear-shaped, with the small end downwards.

In the second case the two eyes presented two lesser degrees of the same condition. In one eye the stroma of the iris was alone deficient below the bridge, the pigment epithelium being left exposed. In the other eye, the space below the bridge formed in part a complete gap in the iris, and was in part filled with pigment epithelium. The developing iris receives its blood supply from two sources—(1) loops of vessels budding off from the anterior ciliary arteries, and (2) branches continued forwards round the sides of the lens from the central hyaloid artery; these form a circle of anastomosis anteriorly. The gap in the iris peripherally in these eyes might be explained by the failure in formation of one of the loops from the anterior ciliary arteries and the bridge, by the normal formation of the anterior circle of anastomosis from the central hyaloid artery.

An outbreak of diphtheria has occurred amongst the nurses and maidservants at the General Hospital, Nottingham, and nine of them have been removed to the Isolation Hospital at Bagthorpe.

THERAPEUTICAL SOCIETY.

At a meeting on Tuesday, January 23rd, at the Apothecaries' Hall, Sir LAUDER BRUNTON in the chair.

Dr. J. NEWTON PITT described the treatment of exophthalmic goitre by antithyroid serum. Graves' disease required long treatment, and though many remedies are beneficial, none are panaceas but antithyroid serum is often of much service. Formerly digitalis, belladonna, potassium iodide, and arsenic were used or an operation was necessary. It is still doubtful whether the disease depends on toxic or nervous conditions. In 1899 the use of the serum from the blood of dogs whose thyroids had been removed, or the dried blood, or in some cases the milk of goats similarly operated on was employed. Five cc. of serum was at first injected subcutaneously, but recently it has been given by the mouth, with equally good results; still each dose costs two shillings and often more than 100 doses are needed, the treatment lasting 5 to 10 weeks. Under this treatment the thyroid and exophthalmos are diminished, the pulse becomes lower, the general health and weight improve, the tremors and the nervous symptoms diminish and the patient is apparently well, but sometimes relapses occur and require the treatment to be resumed. Dr. Pitt has treated six cases by this method, all in women, using also rest in the open air. In one case in five weeks the pulse fell from 160 to 100, and in two months there were no tremors, nor insomnia, and she felt well. In another case of two years' duration, with the antithyroid treatment only, she became quite well in two months, and able to walk four miles. A third case in one week's treatment gained 1 lb. in weight, and the pulse was lowered 10 beats. In another case with a very large thyroid causing dysphagia, the gland was greatly reduced in 14 days and the patient's condition was much improved; in two other cases the pulse and nervous symptoms were ameliorated though the thyroid was not much diminished. The treatment by antithyroid serum is almost always successful, the tremors and the nervous symptoms are relieved, and it is only as a result of nervous affections that death occurs in Graves' disease. No ill results have occurred from this treatment except in one case, in which a patient took 240 doses without consulting the doctor, and symptoms of myxedema occurred, but these were relieved by leaving off the treatment. The flesh of goats deprived of thyroids has been tried without any beneficial result.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A PATHOLOGICAL meeting (the first meeting of the kind in the history of the Society) was held on Friday, February 2nd, the President, Mr. L. A. BIDWELL, presiding.

On taking the chair, Mr. BIDWELL presented to the Society a very tasteful badge to be worn by future presidents at the meetings of the Society. The badge was accepted by Dr. F. Lawrence, in the name of the Society in suitable terms. Dr. Lawrence then invested Mr. Bidwell with the new badge of office.

The following members showed specimens, &c.:—The President: A stone formed round a clinical thermometer removed from the bladder of a woman by supra-pubic lithotomy and sections of an unusual tumour of the omentum removed by operation. Dr. J. A. Coult's: Two stomachs of children, showing pyloric and duodenal obstruction. Dr. George Pernet: Microscopic sections of various forms of unusual skin disease. Dr. J. R. Lunn: Drawings and paintings of various morbid conditions and also specimens of adventitious stones introduced into the bladder by an hysterical female patient, and microscopic sections. Dr. W. L. Harnett: An instructive series of specimens of morbid anatomy including a large cyst of the spleen and many microscopic sections. Dr. Hamilton Wright:

A collection of microscopic sections and specimens of morbid anatomy. Mr. McAdam Eccles: A stomach removed by operation for colloid carcinoma, with recovery of the patient. Dr. J. A. Mansell Moullin: A large uterine fibroid and other specimens removed by operation. Mr. Richard Lake: A most instructive collection of specimens, models, and paintings illustrating various forms of ear disease. Dr. Leonard Mark: The broken umbrella and seared clothes of a woman who was struck by lightning in Hyde Park, but who ultimately recovered. Dr. A. E. Russell: A series of kidneys showing various forms of common pathological change. Dr. Otto Grunbaum: A heart with a gumma of the inter-ventricular septum in which the band of His was involved. The patient during life showed symptoms of Stokes-Adams disease. Mr. J. G. Pardoe: A series of prostates removed by suprapubic prostatectomy. Mr. Woodford: Microscopic specimens of the various forms of spirochæta, including the *Spirochæta pallida*.

Lantern slides of great interest were shown by Mr. C. F. Keetley, of various forms of deformity of the hip, by Dr. A. Morison, of changes in the coronary arteries in a case of angina pectoris, which had apparently affected the ganglion cells, and by Dr. Chisholm Williams, showing the effects of X-rays treatment on certain cases of malignant disease.

THE LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 1ST, 1906.
FRANK T. PAUL, F.R.C.S., President, in the Chair.

ACUTE HÆMORRHAGIC PANCREATITIS.

DR. F. W. BAKER YOUNG said that his patient was a man, æt. 30, and addicted to alcohol. He was taken ill while at work, walked home, a distance of fifty yards, and died within forty-five minutes of the onset of symptoms. At the autopsy the body and tail of the pancreas were found enlarged and infiltrated with fluid blood; the head of the organ was also involved but not to the same extent. There was blood-stained fluid in the lesser sac of the peritoneum and an ecchymosis on the left kidney over the site of its relation with the body of the pancreas. No other lesion was found that could account for death. The following points were of special interest:—(1) Rapid onset and rapid termination; (2) the patient's age; (3) absence of vomiting; (4) absence of pain; (5) the fluid state of the blood no clots having been found even forty-eight hours after death; (6) the engorgement of the abdominal veins with fluid blood; finally, the medico-legal aspect of the case—had the pancreas not been examined the cause of death could not have been stated.

Dr. WM. CARTER drew attention to the similarity of the symptoms in death from irritant poisoning and from hæmorrhagic pancreatitis respectively, quoting the following from Dr. A. J. Chalmers' monograph on "Pancreatitis in Ceylon":—"Especially I desire to draw attention to the legal *post-mortem* form where no mention of the pancreas is to be found, I think that this should be rectified and that in all legal *post-mortem* careful note should be made of the condition of the pancreas."

POSTERIOR VERTEBRAL TUBERCULOSIS.

MR. K. W. MONSARRAT read a short paper on Posterior Vertebral Tuberculosis. After mentioning the primary seats of the disease as it has been found in the vertebral arches, he related two cases. In the one, the disease involved the transverse process, pedicle and lamina in the dorsal region; in the other, it was confined to the lamina of the fourth cervical vertebra on the left side. Both cases were complicated by abscesses and the cervical case also exhibited paralytic phenomena, beginning on the left side and subsequently extending to the right and involving the bladder function. The paralysis in the second case rapidly disappeared after laminectomy and the clearing out of a mass of granulation tissue from the spinal canal.

Dr. T. R. GLYNN related a case of caries of the atlas and axis with displacement of the atlas backwards, in which recovery took place—the patient ultimately dying from internal hydrocephalus. The caries was associated with post-pharyngeal abscess and the condition being recognised, the patient, a girl, was placed on a bed raised at its upper end, her head fixed by a bandage to a rail, the body extended by a weight attached to the feet. All her limbs and the bladder became paralysed and respiration embarrassed. Atropine proved valuable in relieving respiratory trouble. After many weeks she recovered, the last symptoms, those pointing to descending lateral sclerosis, nearly passing away. She entered service and remained well for several weeks, but was re-admitted—comatose. After death, great distension of the lateral ventricles was found. The odontoid process had slipped backwards and upwards; the cord was compressed to the size of a goose quill; the axis and atlas were partly destroyed and ankylosed together. The hydrocephalus was probably caused by the displaced odontoid process thrusting the medulla upwards against the cerebellum and closing Majendie's foramen.

CARDIAC HYPERTROPHY IN GRAVES' DISEASE.

Dr. T. R. BRADSHAW showed a girl, æt. 16, with Graves' disease incompletely developed. There had been palpitation and suffocative sensations for a year. The most prominent sign was hypertrophy of the right ventricle, for which none of the common causes were present. Latterly, slight enlargement of the thyroid had become apparent. Dr. Bradshaw commented on the rarity of demonstrable cardiac hypertrophy in Graves' disease, a fact pointed out long ago by Trouseau.

THE X-RAY DIAGNOSIS OF KIDNEY STONES.

MR. C. THURSTAN HOLLAND read a paper on the X-ray diagnosis of kidney stones. The paper was divided into three portions, the positive, doubtful, and negative evidence of calculi. Illustrative cases were cited and lantern slides shown to prove the value of the positive and the difficulties of the doubtful diagnoses. The paper was based on a series of 76 cases, in 22 of which calculi were shown by X-rays. The value of the negative evidence was discussed, and it was shown that too frequently reliance was placed on plates which were not good enough to warrant a negative opinion; if plates of the proper quality were obtained, then, and then only, was negative evidence reliable. The value of a pressure tube apparatus in taking these radiographs was also dwelt upon.

The PRESIDENT referred to the valuable aid in diagnosing kidney lesions afforded by the urine separator and radiography. Liverpool was fortunate in possessing an exceptionally skilled specialist in each department and he had had many opportunities of testing, and though at first he had not been prepared to give an unqualified acceptance to the results obtained by these methods, experience had assured him that in proper hands they were thoroughly reliable, and of the utmost assistance.

Dr. J. HILL ABRAM said that one of Mr. Holland's cases was a man, æt. 43, who had been sent to him for pain in the right hypochondrium and loin. There had never been any renal colic, or hæmaturia, and nothing could be detected by physical examination. On one occasion Dr. Abram found a few pus cells in the urine. Dr. Holland's report was decisive and Mr. Rushton Parker successfully removed two stones from the kidney. It was an enormous gain to have had such an advance in our methods, and it would enable physicians to recommend surgical interference with much lighter hearts than in the past.

Mr. W. THELWALL THOMAS alluded to the great service X-rays in Mr. Holland's hands had been to him in many cases of kidney stone—even in a case of a large kidney filled with pus and in a very stout patient, in confirming the diagnosis. He would in every case of suspected calculus call in an expert radiographer for confirmation.

The following gentlemen also took part in the

discussion of the paper Mr. Rushton Parker, Dr. Nathan Raw, Sir James Barr, and Dr. T. Welby.

CORK MEDICAL AND SURGICAL SOCIETY.

GENERAL MEETING HELD WEDNESDAY, JANUARY 24TH, 1906.

Professor PEARSON, M.D., in the Chair.

PROFESSOR CUMMINS showed a Cystic Tumour removed by him from a two-parous married woman, two months after birth of second child. She noticed it first in the right iliac region when *æt.* 14, and on her admission to the hospital it extended up to the lower surface of the liver and well across the median line of abdomen, and was so large as to excite wonder that there had been room for it and the pregnant uterus together. There were no untoward subjective symptoms, and the urine was free from abnormal constituents. A cystoma of the broad ligament was diagnosed and an operation undertaken. A median incision was made, and transversely running vessels were found entering the tumour; these were ligatured and the growth removed without difficulty. There was no connection with ovary tube, or ovarian vessels. He was reluctant to remove the kidney with the tumour, but the cyst was so intimately fused with that organ as to render this step imperative. The huge cavity left was packed with gauze, for which a drainage tube was in due course substituted, and patient's recovery was uneventful.

Dr. MOORE reported on the cyst, whose origin he attributed to an error of development—a persistence of part of the Wolfian body. In this case, the capsule of the cyst had split to receive the kidney with whose capsule it was inseparably fused. He demonstrated the normal ureter, thus excluding hydronephrosis.

The CHAIRMAN characterised the cyst as a unique specimen, and agreed with Dr. Moore's opinion as to its genesis. He was a bit dubious about removal of kidney, but thought he most likely would have done the same himself.

The CHAIRMAN showed a tuberculous kidney and ureter that he had removed from an unmarried woman, *æt.* 28. She had been a domestic servant in England, where the symptoms—pyuria, &c.—showed themselves. Coming back, she put herself under his care. Having examined the bladder with cystoscope, which revealed no cystitis, he used Luys' Segregator, and found, on estimating urea in healthy urine coming from the right ureter, that the daily excretion was 300 grains. Thinking this satisfactory, he operated, making the usual Howard Kelly incision—an incision he had always used before Kelly's book came out—and found evidence of considerable peri-nephritis and great thickening of the ureter. Having secured the renal vessels by clamping them, he clamped the ureter as far down as possible, and then ligatured it. He left the forceps on the renal vessels for forty-eight hours. Post-operative vomiting was very troublesome, as is common in these cases. He thought the usual explanation of this symptom, *viz.*, increased strain on healthy kidney, incorrect, inasmuch as the diseased organ had been functionless for some time. A more probable explanation was excessive humidation of coeliac plexus following section of the sympathetic fibres going to the kidney. He pointed out the advisability in these cases of dealing with the vessels first, and then with the ureter, and raised the question of the order of infection. On the latter point there was some discussion, and the general opinion favoured the idea that the disease was primary in the case under review.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, February 10th, 1906.

RHINITIS.

COMMON cold in the head should no longer be considered a simple affection which gets well a little sooner when left alone than when treated. Coryza is frequently the first stage of an infection which may be followed by very grave consequences. By its means microbes take possession of a natural inlet of the organism.

The functions of the nasal cavities, says Professor Lermoyez, are not only to acquaint us with the different odours, but also to warm the inspired air, to charge it with vapour, to purify it in arresting particles of dust, and to destroy or neutralise on the spot infectious germs by the bactericide effect of the mucus which they secrete.

When by inflammation these actions cease, a series of affections may result which Lermoyez classes as follows:—Nasal obstruction, infection of nasal origin, reflexes of nasal origin.

Nasal obstruction is rapidly produced in infants by reason of the narrowness of the canal that a slight inflammation and swelling of the mucous membrane obturates almost completely. The child cannot draw the breast, it experiences a sense of choking and throws itself back with vivacity. When the impermeability is very pronounced, the child may succumb from inanition or asphyxia.

In infants, rhinitis is frequently the cause of infection of all the respiratory tract, and also of the middle ear; the secretion from the ear is purulent, and contains numerous streptococci and pneumococci, the virulence of which can provoke septicæmia.

There are certain differences in the frequency & complications of coryza in infants, children, and adults. Purulent sinusitis is rarely observed in infants because these cavities are not well developed. On the other hand, inflammation of the middle ear with certain reaction of the tonsils are the rule. All the adenoid tissue of the pharynx is engaged, and these inflammations are frequently accompanied by irritation of the lymphatics, which sometimes end in suppuration. But in a large number of cases the lymphoid tissue becomes hypertrophied and is converted into adenoid vegetations so frequently observed in children.

Broncho-pulmonary complications of coryza are well known, and it is to-day proved that careful antiseptics of the nose and the pharynx constitutes, with the removal of vegetations, the best prophylactic means against recurrent bronchitis in the young.

Nasal inflammation can be propagated to the eyes producing phlyctenular keratitis, conjunctivitis, blepharitis, &c., impetigo of the face, and thickness of the upper lip.

If the lesions of the nasal cavities become chronic hypertrophy of all the adenoid tissues of the nose, pharynx, and tonsils will result, and frequently the repulsive infirmity called *ozena* supervenes.

Coryza is not of itself a grave affection; it becomes so by complications. It should be treated with care.

To arrest coryza a host of remedies have been recommended, but that of Brand seems the best.

Pure phenic acid,	1 drachm.
Liq. ammonia,	1 drachm.
Proof spirit $\frac{1}{2}$ oz.	
Water, $\frac{1}{2}$ oz.	

Pour 10 drops on a piece of blotting paper and let it be inhaled through the nose for a few seconds.

It may be repeated every hour.

If the child has already suffered from complications from a previous coryza, great precautions are necessary; he should be put to bed with the legs wrapped in cotton wadding, warm drinks to provoke perspira-

tion, and a few drops of belladonna given in a little water.

Locally, pulverisations of cocain (1 per cent.) are very useful to facilitate respiration, but they should not be ordered for children under æt. 12. Solutions of menthol and oil (1—50) or resorcine (1—50) are frequently instilled into the cavities with benefit.

The general condition of the patient should not be neglected; quinine, in case of fever, and a gentle purgative. Later, the state of the nose and of the posterior nasal cavities should be examined for possible vegetations.

Coryza in the infant is a really grave affection. It does not know how to breath through the mouth, and the nasal cavities being very narrow, they are completely obstructed by the inflamed membrane and the secretion.

Respiration is very difficult at all times, but much more so when lying down than when sitting up, for when sleep comes on the tongue falls back against the velum obstructing any air that may come through the mouth.

As soon as the little patient commences to doze, a snuffing sound is heard, and the child wakes up choking, makes several large respirations in its thirst for air and cries. Sometimes this attack of dyspnoea assumes the intensity of an attack of spasm of the glottis; the child is frightened, the cartilages of the nose dilate, the cry is almost inaudible, the respiratory movements are rapid, and agitated, and cyanosis is imminent.

All these troubles end by affecting profoundly nutrition, the broken sleep, the difficulty in taking the breast contribute to the weakening of the frail organism. The infant gets thin, loses its strength, and succumbs either to convulsions or to broncho-pneumonia.

However, this fatal termination is not frequent, and the malady if treated in time gets well with little trouble.

The first thing to be done is to free the nasal fossæ from all mucosities. This can be effected by the use of the Politzer douche (dry douche), which removes the secretions very rapidly. The insufflation of air should be repeated each time before putting the child to the breast. The nose should not be irrigated. Local antiseptics may be obtained by a solution of olive oil and menthol (1—100), injected into the nostrils every three hours.

When the coryza diminishes, the following powder may be blown into cavities.

S.N. of bismuth,
Boric acid 2 drachms;
Resorcine, 30 grs. ;
Menthol, 4 grs.

GERMANY.

Berlin, February 10th, 1906.

At the meeting of the Society for Folk's-Hygiene Professor Orth discussed some aspects of the

ORIGIN AND PREVENTION OF TUBERCULOSIS.

In answering the question whether in any way bacilli that entered the system by kissing, by food, by breathing bacilli-containing dust, the individual receiving them must necessarily sicken of the disease, he said, "God be thanked, No!" We should then all die. As regarded the consumption of milk or flesh from animals suffering from bovine tuberculosis, the danger was not great, especially if these foods were not consumed raw. Moreover, in the parts of the animal that were sold for food there were but few bacilli. If the food containing tubercle bacilli was cooked, it did no harm. The same applied to milk. Whoever never drank unboiled milk would never infect himself with tubercle through the milk. Mothers whose children could not bear boiled milk should suckle their children themselves, and if they were not able to do that, they should have recourse to a wet nurse. In order to retain the system in good condition to resist the influence

of bacilli, he recommended strict inspection of meat, also of dairies, notification of disease, instruction in schools, disinfection, and hygiene of dwelling-houses. As the existing institutions for the treatment of consumption were for the milder stages of the disease, others must be erected for the bad cases. The luxurious fitting up of present institutions were superfluous, and not practical. Light, air, and strengthening of the system were the principal weapons against tuberculosis, and generally a hygienic mode of life both of sick and well, general cleanliness, and good food that strengthened the body. Every measure that raised the price of bread and meat furthered tuberculosis, and, on the other hand, every measure that cheapened the people's food was a remedy against tuberculosis. Special means of strengthening the system artificially so that the individual should become more resistant against tuberculosis, did not yet exist. Whoever should discover a means of rendering the human subject immune against tuberculosis would be the greatest benefactor of his race.

At the Society fur Innere Medezin, Hr. Manasse showed a patient who first came under treatment in 1902 with a swelling on the chin, the result of a scratch, as was supposed. The swelling appeared to be of a fundiculous nature, and was incised; it was then seen that the swelling reached to the bone. The incision brought no relief, and in the course of the next few months metastatic abscesses formed in the middle of the neck, in the sheath of the great vessels, in the right buttock, and the right half of the pelvis, and on the other side also, in the thigh, which on incision showed the same character as the original one. Four months later matters came to a standstill, the patient had recovered somewhat, and at his wish was sent home. Only a short time afterwards, however, he returned in a decrepit condition and with great pain in the right lower part of the thorax. Examination showed dulness below on the right lessened vesicular breathing at the spot, but normal above, the lower margin of the lung normally movable on respiration. The liver was not enlarged, but a further examination was practicable on account of tension. A subphrenic abscess was diagnosed, and this on operation was found to be correct. There was a large cavity about the size of the adult head between the convexity of the liver and the diaphragm. Recovery gradually ensued; but in the beginning of last year suppuration again took place in the right lower part of the chin, which, however, healed after a longish time. The patient has since then had no further attack and was now fit for work.

AUSTRIA.

Vienna, Feb. 10th, 1906.

ASCITES AND TALMA OPERATION.

At the Gesellschaft, Frank showed two patients, a man and a woman, on whom he had operated for ascites, the result of cirrhosis. The female case seems to have been of a congestive nature, and was therefore easily removed, but the male required more heroic treatment for his relief, as the spleen had to be brought to the surface and fixed after Talma's method of relieving ascites, which he affirmed was successful with all the intraperitoneal organs, such as spleen, liver and gall bladder.

His theory was to establish a collateral circulation between the parietes and the internal organ by fixing the later, after wounding or rawing its surface, in the parietal incision, where adhesion subsequently took place and a new vascular circulation produced. The easiest of these operations is with the omentum and peritoneum, which are accessible, while the liver, spleen, and gall duct require more expert knowledge. In cirrhosis of the liver, where the organ is greatly shrunk and the vessels compressed into narrow compass, the dragging forward of the organ into the parietal wound becomes a difficult and dangerous undertaking. The fixation of the spleen is not such a difficult operation, although when the organ is small and shrunken

considerable difficulty is experienced in retaining the organ in the wound, but where it is enlarged little or no difficulty exists.

Care should be taken to secure the peritoneum carefully to the margin of the laparotomy wound before attempting to fix the organ. This difficulty may often be troublesome to the surgeon as in the present case, where the muscular portion could not be easily caught.

When the spleen lies above the ribs firmly fixed in a shrunken condition as it was in the present case, it is almost impossible to perform the operation with any hope of success.

Notwithstanding the hopeless aspect of this case the operation was commenced on December 4th, 1905, by a long incision, 10 centimetres in length, along the margin of the tenth rib, while a part of the eleventh was resected whereby the diaphragm and pleura could be raised to admit of access to the organ, where it was found hard and shining through the peritoneum like a mass of porcelain.

With great difficulty its lower pole was dragged forward and fixed to the thoracic wall with the hilus remaining in the peritoneal opening. In this position it was firmly fixed by means of sutures and the whole finally covered with skin. The spleen thus lay subcutaneously embedded firmly between the ribs above and the muscles below, and allowed to heal. In the course of four days pneumonia marred the healing process and increased the ascites to an enormous extent for a considerable time after the operation, but it has now quite disappeared, leaving the patient free and comfortable without any sign of dropsy.

Teley said he had operated on a man, *æ*t. 26, who suffered from syphilitic cirrhosis and ascites. He tapped three times without success, and as an ultima ratio resolved on Talma's operation to fix the omentum in the abdominal wound for collateral circulation. The veins were very large, forming a *caput medusæ* after every tapping. When the incision was made the veins stood open like large quills. The omentum majus was fixed in the wound, but the peritoneum could not be, as it was firmly adherent to bowel and liver and could not be removed. The wound was closed and all firmly secured with sutures, but with no better success than the tapping. After ten days the stitches were removed, while the ascites went on, and eight litres of water were again drawn off. Some time after the patient died from inanition. Teley thinks that the operation is successful in a few cases, but not in cases like this, where the vessels are so widely distended.

Eiselberg said he had often fixed the spleen in the wound without the previous fixing of the peritoneum, and had obtained good results.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROFESSORSHIP OF MEDICAL JURISPRUDENCE, EDINBURGH UNIVERSITY.—This vacant post has been filled by the appointment to it of Dr. Harvey Littlejohn, the son of the late occupant of the chair. The appointment was announced on the 5th instant, and it may safely be said that none which has been made in recent years has been received with such unanimous approval. When Sir Henry Littlejohn's retirement was intimated, it was universally felt in medical circles in Edinburgh that the Secretary of State had no difficult task before him in finding a successor, and that no one could more fittingly occupy the chair than the candidate who has now been selected. Professor Harvey Littlejohn is 44 years of age, and took his degree in medicine in 1886; after some time spent in resident hospital appointments he studied abroad in Vienna, Berlin and Paris, returning to Edinburgh in 1888 to assist his father in teaching medical jurisprudence. In 1891 he received the important appointment of medical officer of health for Sheffield, where he remained for five years, returning to Edinburgh again in 1897 to

lecture on Medical Jurisprudence in the College of Surgeons. Professor Harvey Littlejohn is a Fellow of the Royal Society of Edinburgh, and was a Senior President of the Royal Medical Society. His contributions to the subjects of Medical Jurisprudence and Public Health are numerous and widely known; he is a member of the Sanitary Institute, the Epidemiological Society, the Society of Medical Officers of Health, and the Society for the Study of Inebriety. He is also one of the editors of the *Edinburgh Medical Journal*.

SCOTTISH UNIVERSITY PARLIAMENTARY ELECTION. Polling for Glasgow and Aberdeen Universities closed on February 6th, and the results were officially announced next day, as follows:—Sir Henry Craik, 3,543; Professor Murison, 2,450; Professor W. R. Smith, 1,240. Two days later the figures of the Edinburgh and St. Andrews election were published:—Sir John Batty Tuke, 4,893; Mr. St. Loe Strachey, 2,310. In a short address at the declaration of the poll, Sir John Tuke said that he had received support from electors of every shade of political opinion, and that he regarded his victory as a great academic gain.

ROYAL MEDICAL SOCIETY.—The annual dinner took place in the Society's hall on February 7th, and was attended by a large company of medical men. Professor Clifford Allbutt was the guest of the evening.

QUEEN'S NURSES IN EDINBURGH.—An important extension of the premises of the Queen Victoria Jubilee Institute for Nurses was opened on February 9th, by the Countess of Eglinton, in the unavoidable absence of the Duchess of Buccleuch. In opening the new flat the Countess of Eglinton spoke of the great services rendered to the community by the nurses, who made it possible to perform operations in the homes of the poor, and thus spared the over-crowded hospitals. In addition, the nurses spread a knowledge of sanitary laws, and the care of health among the community in which they worked. She pleaded for an extension of the work of Queen's nurses, in remote and outlying parts of the country, for a home of rest and convalescence for the nurses, for a pension fund, and for a sick fund. For all these greater generosity on the part of the public was required; at present they needed income rather than capital to carry on and extend their work.

BELFAST.

DONATION TO THE ROYAL VICTORIA HOSPITAL.—At a meeting of the Board of this hospital, held last week, it was announced that a letter had been received from Dr. H. L. McKisack, one of the honorary physicians to the hospital, intimating that the trustees of the late Mr. Henry Matier, of Belfast, purposed handing over to the hospital a sum of £5,000. Dr. McKisack is a son-in-law of the late Mr. Matier, who was a well-known merchant in the city. This handsome addition to the funds of the hospital will be most welcome, in view of the increasing work of the institution.

THE MEDICAL CURRICULUM.—Considerable interest is being taken at present in the subject of the medical curriculum in the Royal University, as it is known that some of the northern members of the Senate are pressing for certain changes. Two such changes have been widely discussed, and would be generally viewed with favour. One is the simplification of the course in physiology, so that it would interfere less than it now does with clinical work in the later years of the curriculum, and another proposed change is the reintroduction of compulsory attendance at a children's hospital. The two changes are of course connected, for it is obviously impossible to lengthen the course, and if there is to be more hospital, there must be less college work. It certainly does seem rather absurd, considering the vast importance of diseases of children in practice, that a young man may receive his diploma and licence to practise from the Royal University without ever having spent ten minutes in the examination of a sick child, though he has spent scores of hours in making tracings of muscle curves with complicated electric apparatus, which he is not likely to see again in all his future life. It is no doubt right that the

Royal University should maintain a high standard for its degrees, but some common-sense must be exercised that the standard may not be too high for a poor country. If it is found that the five years' curriculum is not nearly sufficient for the great majority of students to obtain a degree, it is clear that the standard is too high, for the majority of Irish students come from families who often enough have difficulty in keeping the student for even the minimum of five years. The whole subject certainly merits careful attention.

HEALTH OF NEWTOWNARDS.—It is not many months since this little town was visited by a severe outbreak of fever, and now it is the seat of an outbreak of measles and whooping-cough. A meeting was held in the Town Hall last week, convened by the Urban Council, to which all managers of day and Sunday schools and the principal teachers were invited. The position of affairs was explained by Dr. Jamison. Since the 1st of January there had been ten deaths from measles and seven from whooping-cough. It was arranged to close the schools for a week for thorough cleansing and disinfecting, and to let the parents of scholars know the risks run by sending children to school from infected houses.

LETTERS TO THE EDITOR.

"MEDICINE AS A GREAT ELECTORAL POWER."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question dealt with under the above heading in your editorial "Note" on February 7th, deserves serious consideration. The letter to which you allude was written by Sir G. C. T. Bartley, whose heckler, no doubt, acted upon the suggestion that candidates for Parliament should be questioned on behalf of medical reform. That this advice received little response I am able to vouch, a fact which speaks well for the common-sense of the profession. The instance you refer to exemplified the mischief which might have been caused by wide adoption of the plan. Sir G. Bartley's heckler placed himself, if not his profession, on a level with those egoists, faddists, and fanatics who loudly proclaim their indifference to every great national and imperial interest, and devote themselves to the cult of the insignificant cause to which they are devoted. Perish India, away with the Colonies, down with the Empire, but let us before all prohibit vivisection, abolish vaccination, or promote legislation for the advantage of our own particular trade or profession. In the current papers there appeared a letter from the secretary of a notorious anti-vivisection society, urging all voters in a county division near London to vote for a certain candidate regardless of any other consideration, because he had pledged himself to support the Dogs Protection Bill. The committee of the society appealed "to all humane voters to concentrate their efforts for the return of Mr. —, and vindicate the claims of man's best friend for exemption from the tortures of the laboratories." A heckler on behalf of a profession, in taking up a position such as Sir G. Bartley rightly denounced, creates the belief that he is not actuated by public spirit, but by the narrow spirit of Trades Unionism which seeks its own advantage regardless of the interest of the community and the State.

How is it possible for a Parliamentary candidate to pledge himself to support amendment of laws with the scope and character of which he is entirely unacquainted, and which require considerable study before they can be understood. If the candidate be honest he must say this; if he be of the disingenuous variety, he may promise to give sympathetic attention to the question or even to help promote a change in the laws.

Lawyers in Parliament are not cognisant of the vast injury to the public which the present state of the law allows and encourages; they do not understand that whatever benefit medical reform might bring to the

profession, it would confer far greater advantages upon the people, and until the facts are brought home to them it is hopeless to expect that the drastic changes in the laws so urgently called for can be brought within the scope of practical politics. Not only ignorance but powerful and active prejudices have to be overcome. How enlightenment of public opinion throughout can alone be accomplished I have in previous letters explained. Growing knowledge of all the circumstances confirms me in the belief that it can be done only through the medium of a Royal Commission.

I am, Sir, yours truly,

HENRY SEWILL.

February 8th, 1906.

TREATMENT OF RESERVOIRS WITH CUPRIC SULPHATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read the remarks in THE MEDICAL PRESS of Jan. 17th, on the Newport experiments in the treatment of reservoirs with cupric sulphate together with those made at Manilla with the view of killing the comma bacillus, with interest. The comments in reference to the danger of supplying copper sulphate solution to the public as the result of its use is, I fear, likely to prejudice water authorities and the public against the method of treatment. In my paper on the subject, which appeared in *Water*, Dec. 15th, 1905, it was clearly shown that the copper sulphate was precipitated very rapidly. This precipitation of the copper salt can be completed, if the water does not contain sufficient carbonate, by the addition of lime which will further help to clarify the reservoir water. The public need have, therefore, no fears in respect to the possibility of being poisoned as a result of the copper treatment, if the process is carried out under the supervision of a competent chemist.

I trust, therefore, that you will correct this impression in your next issue in order that no misunderstanding may arise as to any possible injurious effects upon the potability of the waters so treated.

I am, Sir, yours truly.

J. HOWARD-JONES.

Newport, Mon., Feb. 5th, 1906.

THE SCIENCE OF THE TEMPERANCE QUESTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Do you not think that it would be interesting and of practical value if we had the general opinion of the medical profession on the temperance question? Not very many years ago, Dr. Todd and his disciples were strong advocates for alcohol in the treatment of disease.

If a man were brought into a London hospital with a broken leg he would be ordered 8 oz. of brandy, before anything was done. That was the rule of the day. Things have changed, or rather, theory has been made to give place to practice, and the two sometimes do not work together.

We are now beginning to ask what is alcohol, and we see cases coming into court on the question of what is, and what is not "whiskey."

The whole question seems to reduce itself to the pure chemistry of fermentation; a process of singular character and difficult to deal with. Do you not think that it would be well to draw a line between fermented liquids, and alcohol? We might allow simple fermented liquids to be sold under very different conditions to alcohol. To estimate any fermented liquid by the amount of alcohol it contains is questionable, at the least.

I am, Sir, yours truly,

INQUIRER.

P.S.—It is well to bear in mind that we can stop fermentation by adding some spirit to the fluid, as is done often in Spain and other countries, to obtain and sweeten wine.

MEDICAL NEWS IN BRIEF.

The Royal College of Physicians of Ireland.—Address to the Lord-Lieutenant.

AN address of welcome was presented to Lord Aberdeen, the new Lord Lieutenant of Ireland, by the President and Fellows of the College on the 7th inst. His Excellency received the address personally in the Throne Room of the Castle, and after hearing it and replying, had each of the deputation presented to him individually. The following is the text of the address :

May it Please Your Excellency,—We, the President and Fellows of the Royal College of Physicians of Ireland, desire to approach Your Excellency upon your arrival in this country as the representative of His Gracious Majesty the King with a cordial welcome and an expression of our devoted attachment to the Throne. The Royal College of Physicians of Ireland, founded in 1667, received in 1878 and 1890 additional powers from the late Queen Victoria, and during last year a supplemental Charter was granted by His Majesty the King which has placed the College on an equal footing with the sister Colleges in London and Edinburgh in regard to its membership. The President and Fellows of the College have ever been mindful of the great and important functions entrusted to them, both by His Majesty and by His Majesty's Royal predecessors. The President and Fellows have at all times sought to further the advancement of medical science, and to secure a succession of highly-trained physicians for the service of the State. A considerable number of the medical officers in the Navy and the Army hold the Diplomas of this College, while most of those holding the position of medical officer under the Poor Law System in Ireland are also Licentiates of the College. The President and Fellows from time to time have placed their services at the disposal of the Government, more particularly in devising and giving effect to measures bearing on the public health, and upon the present occasion they desire to assure Your Excellency of their readiness, now as in the past, to afford His Majesty's Government their hearty assistance in all matters relating to medicine and the health and welfare of the people.—W. J. SMYLY, President; JAMES CRAIG, Registrar.

His Excellency replied as follows:—

Mr. President and Gentlemen,—I appreciate very heartily the visit of this large and influential deputation to present the address of loyalty and good wishes to which we have just listened. I need hardly assure you that I recognise and appreciate the far-reaching importance and value of the work of the great and beneficent professional calling which has, so to speak, its headquarters, so far as Ireland is concerned, in your ancient and honourable College. I note also with pleasure and interest what is stated in your address regarding the practical share offered and exercised by your institution in the promotion of those measures for the maintenance of the public health, which it is the duty of the Government to maintain or encourage. It is, of course, impossible to over-estimate the national importance of the effective carrying-out and improvement of such measures in relation to sanitation and public health. It is, no doubt, also most desirable to foster that without which even the most skilful and scientific systems cannot have their full scope and effect—namely, a public opinion which will recognise and support the value and the application of such measures. Assuring you of my hearty good wishes for the success of all your efforts in these and other directions, I again thank you for your attendance here to-day.

On Friday last an address of welcome was presented by the Royal College of Surgeons in Ireland, which was graciously received by His Excellency, who in his reply alluded to the pleasure with which he looked forward to being present to the annual dinner of the college.

The Otolological Society of the United Kingdom.

AN ordinary meeting of this Society was held at 11, Chandos Street, on Monday, Feb. 5th, 1906, the President, Mr. Cumberbatch, in the chair. Messrs. Fitzgerald Powell, J. S. Barr, E. S. Steward, A. K. Gordon, and H. J. Davis were elected members. After a short address by the President, Mr. Macleod Yearsley showed a specimen of epithelioma of the pinna removed from a man, aged fifty-two, and a patient in whom the left tympanic membrane was of a dark slate-blue colour. The latter case attracted much attention, but no adequate cause could be assigned for the phenomenon. Dr. Albert A. Gray gave a photographic and lantern demonstration of some pathological conditions found in the human labyrinth, and on some points in the comparative anatomy of that organ. Other cases were shown by Mr. Lawrence, Mr. Whitehead, Dr. Milligan, and Dr. Dundas Grant.

Royal College of Surgeons of England.

At an ordinary meeting of the council, held at the college on the 8th inst., the following candidates were admitted members of the college:—L. E. Acomb, Cardiff and Middlesex; E. L. Atkinson, St. Thomas's; C. K. Attlee, Camb. and St. Thomas's; J. S. Avery, Bristol; A. Barber and B. H. Barton, St. Bartholomew's; A. Beeley, Leeds; C. Bennett, St. Thomas's; L. C. Blackstone, Univ. Coll.; R. O. Bodman, Bristol; C. W. Bowle, St. Thomas's; D. W. A. Bull, Camb. and St. George's; R. Burgess, Camb. and London; W. B. Burr, Middlesex; G. Chaikin, Sheffield and London; A. de C. C. Charles, Camb. and St. Thomas's; H. D. Clement-Smith, St. Bartholomew's; A. F. Clough, Guy's; O. C. P. Cooke, London; G. L. Coe, Camb. and Liverpool; N. R. Cunningham, Camb. and St. Thomas's; H. F. Curl, Camb. and London; F. B. Dalglish, St. Thomas's; A. P. Day, Camb. and London; H. L. Deck, Sydney and St. Bartholomew's; C. C. A. de Villiers, Guy's; A. N. Dickson, Camb. and St. Thomas's; A. Dinnis, Charing Cross; W. A. E. Dobbin, Cardiff and St. Mary's; G. S. Earl, St. George's; G. B. Edwards, London; J. Evans, Camb. and St. George's; T. Ll. Evans, Cardiff and Univ. Coll.; A. H. Fardon, Camb. and St. Thomas's; A. R. Fisher, Leeds and King's Coll.; J. E. Foreman, London; A. T. W. Forrester, St. Bartholomew's; C. W. Gibson, Guy's; J. N. Glaister, Univ. Coll.; J. M. P. Grell, Camb. and King's Coll.; J. Grogono and R. M. Grogono, London; G. W. Hardy, Leeds; R. F. Hebbert, St. Thomas's; G. H. Heron, St. Mary's and Liverpool; V. C. Honeybourne, Camb. and St. Thomas's; N. G. Horner, Camb. and St. Bartholomew's; F. R. Hotop, New Zealand; J. I. Jaffe, Dublin and King's Coll.; R. R. James, St. George's; E. C. Jones, St. Thomas's; H. T. Jones, Univ. Coll.; W. H. Jones, Manchester and St. Bartholomew's; E. G. Kelgren, Camb. and St. George's; T. W. Kirby, Toronto and Guy's; H. E. Kitchen, Camb., Manchester, and St. Mary's; T. B. Layton, Guy's; A. L. Loughborough, St. Thomas's; A. H. McCandlish, London; W. St. C. McClure, Sheffield, Univ. Coll., and London; J. E. R. McDonagh, St. Bartholomew's; S. G. MacDonald, Camb. and St. Thomas's; W. J. O. Malloch, Toronto and London; L. Myer, Guy's; J. C. A. Norman, London; N. H. Oliver, Guy's; W. H. Orton, Camb. and St. Bartholomew's; W. S. Orton, Guy's; C. M. Page, St. Thomas's; E. W. M. Paine, St. Bartholomew's; J. W. Parker, Cardiff and Univ. Coll.; M. C. M. Pitkin, Camb. and St. Thomas's; H. R. Prentice, St. Bartholomew's; W. P. Purdom, Guy's; H. E. Quick, St. Bartholomew's; A. Randle, Univ. Coll.; S. Reader, Guy's; M. J. J. R. Rigoulet, Paris; W. O. Sankey, St. Thomas's; E. Schenck, Freiburg; F. Shingleton-Smith, Camb. and Bristol; C. A. Stidston, St. Bartholomew's; J. Tate, Univ. Coll.; G. M. Taylor, and F. Thompson, London; E. M. Thomson, St. George's; A. C. Watkin and J. A. Watt, Univ. Coll.;

L. White, Westminster; H. B. Whitehouse, St. Thomas's; E. D. Whittle, Univ. Coll.; W. D. Wilkins, Manchester; E. Wilkinson, Birm.; A. H. Williams, London and Durham; W. T. Williamson, St. Bartholomew's; C. J. Wilson, Camb. and London; M. R. O. Wilson, Bristol; J. H. Wolfe, London; H. D. Wyatt, Guy's.

The following received diplomas in public health (granted jointly with the Royal College of Physicians): A. C. Birt, H. Caird, H. Chesson, J. M. Collnys, G. Corcoran, J. Gillies, F. Harvey (captain R.A.M.C.), G. H. Lock, G. E. Malcomson, P. K. Muspratt, J. F. Northcott, O. H. Peters, J. W. S. Seccombe (lieutenant, R.A.M.C.), F. B. Skerrett, L. P. Stephen (captain, I.M.S.), P. G. Stock, T. B. Winter (lieutenant-colonel, R.A.M.C.), C. H. Wright.

The Election of Direct Representative for Ireland.

In view of the slight majority obtained by the successful candidate, Dr. Leonard Kidd, at the recent election, Sir William Thomson has asked for a recount, and a scrutiny of the votes. This re-count commenced at 10 a.m. yesterday morning, but at the time of going to press we are unable to say whether it has been possible or not to finish it in one day. If a close scrutiny is to be made of each vote, we fancy that several days must elapse before the result is known.

West London Medico-Chirurgical Society.

THE annual dinner was held at the Hotel Great Central, on Wednesday, February 7th, the President (Mr. Bidwell) being in the chair. There was a large attendance, including the Presidents of the Medical and other societies, and the Director-General of the Army Medical Service. The latter pointed out the pressing need for the formation of a Civilian Army Medical Reserve, to take on the duties, at any rate in part, of the R.A.M.C., which would, in the event of a great war, of necessity be to a large extent withdrawn from this country. He referred sympathetically to the scheme initiated by the West London Society for the formation of such a Civilian Reserve.

The Case of the Feeble-Minded.

THE Royal Commission on the care and control of the feeble-minded sat again last week at the Royal Commissions House, Westminster. Lord Radnor presided, and there were also present Mr. Byrne, Mr. C. Hobhouse, M.P., Mr. H. D. Greene, K.C., Mr. W. H. Dickinson, M.P., Mrs. Pinsent, Dr. Needham, Mr. Chadwyck-Heale, K.C., Dr. Dunlop, the Rev. H. Burden, and Mr. Mothersole, secretary. Mr. J. W. Willis Bund, chairman of the Worcestershire County Council, quarter sessions, and Education Committee said he thought that in respect of uncertified persons, local authorities should be bound to take steps to supplement the contributions made by the State and the locality by payments from the earnings of these persons as far as possible or by obtaining contributions from his property or his friends. At present there was a decided objection to spend anything beyond the poor-rate, or to adopt the Elementary Education (Defective and Epileptic Children) Act, 1899, with the result that no effective means were taken for dealing with uncertified persons, and therefore things went from bad to worse. Uncertified children required their education to be continued long beyond the age of 16 if any good was to come. It was therefore necessary to detain the children longer. The second step was a colony or home for uncertified persons, where they would be kept and properly looked after. Persons who could neither work nor be improved should be drafted off either to asylums, to workhouses, or to a special colony. Evidence was also given by Dr. P. W. Macdonald, on behalf of the Dorset County Council; Dr. C. E. Liesching, chairman of the Lunacy Committee of the Tiverton Town Council, the Rev. W. F. Norris, rector of Barnsley; Mr. Alderman G. Pearson, Bristol; and Mr. D. T. Cowan, director of education, county of Southampton, and Mr. F. G. Barnes, hon. secretary of the National Association of Teachers of the Deaf. The Commission adjourned.

LITERARY NOTES.

Who's Who becomes every year a more substantial and more indispensable book of reference. As a comprehensive and accurate dictionary of current biography it is simply unique, and is now found on the study table of the medical man as a stock volume of reference. Its yearly compilation must involve an immense amount of painstaking labour, but on the other hand there is a solid recompense in the production of a standard annual reference book. Its well-known and popular editor, Mr. Douglas Sladen, may be congratulated upon the great and increasing prosperity of Messrs. Black's useful publication.

THE bones of the illustrious Dean Swift might well move in tremors of cynicism and anger at "*Laputa*," revisited by Gulliver Redivivus in 1905 (London: Hirschfeld Bros., Ltd.), a superficial but amusing plagiarism of his motive, if hardly of his style. The unseemly revivification of Gulliver, still in his adventurous frame of mind, would seem to show that after nearly two hundred years of silence, his enterprise and ingenuity had undergone deplorable degeneration. If we remember rightly, the illustrious traveller set out for Laputa in 1706, and in the records of that adventure, succeeded in admirably expressing in skilfully moulded language, the eccentricities and extravagancies of thought and action of the philosophers and would-be scientists of the Queen Anne period. The main object of the record of this "*Second Voyage to Laputa*" is to caricature present-day methods and manners, science and politics. The work is certainly amusing, and the view of ourselves through Gulliverian spectacles might well teach us most necessary lessons.

"*Operations Vade Mecum*," by Prof. E. Leser, of Halle (published by S. Karger, Berlin), is a work intended specially for country practitioners, who may be compelled to operate on emergency cases; in the small space of 180 pages an attempt is made to describe the technique of all operations likely to come under this heading. Prof. Leser has carried out well an exceedingly difficult task, his descriptions are clear, but of necessity concise, such operations as hernia and tracheotomy are given, as they deserve, extra space; the treatment of perforative peritonitis is very briefly dealt with, while the treatment of the frontal sinus and rhinoplastic operations might well be omitted from such a work without diminishing its value. The book is profusely illustrated, but the pictures, most of which are from photographs, are somewhat lacking in clearness.

OBITUARY.

ALLAN CUTHBERTSON SYM, M.D. EDIN.

We regret to record the death of Dr. Allan Cuthbertson Sym, which occurred last week, at Edinburgh. Dr. Sym was the fourth son of the late Mr. William Sym, and a brother of Dr. W. G. Sym, ophthalmic surgeon, Edinburgh, and Sheriff-Substitute Sym, Perth, who was formerly attached to the Edinburgh Courts. Deceased was educated at Craigmount and Edinburgh University, and was an M.B., C.M., and M.D. of the latter. He was in practice for about twenty years in Morningside. His comparatively early death will be a matter of deep regret amongst an unusually large circle of patients and friends.

It is reported that President Roosevelt has ordered a strict investigation into the facts behind a statement by Professor Wiley, the head of the Chemical Bureau of the Agricultural Department, to the effect that more than 3,000,000 children die annually in infancy because of being dosed with nostrums and soothing syrups and fed on bad milk.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

The Position of the Struggle against Carcinoma Uteri.—E. Opitz (*Monatssch. f. Gebursh. und Gynakol.*, January, 1906) says the time has come when the late results of the radical abdominal operations can be recorded, and an opportunity given for comparison with the vaginal methods. The effort to be as radical as possible, and at the same time to prevent the immediate dangers of the operation has been an incentive to the correction of the technique. The results must become better when the patients are seen as early as possible. Winter has done much for this by his instruction of women in general, as well as midwives and physicians. He has found many followers, and it can be hoped that everywhere the success of his work will make itself felt. By this means the greatest advance will be made. Regarding the method of operation, the abdominal route is now most favoured on account of the greater, far greater, number of permanent cures. We are now able to satisfy Winter's claim for five years' observation. Still in some hands the abdominal method did not give good late results, and therefore so much the more valuable for criticism are the microscopical reports on the tissues removed at operation, and *post-mortem*. Pankow found in only one-fifth of the cases an agreement between the clinical diagnosis and the microscopical report regarding the condition of the parametrium. A parametrium which seems quite free can be completely infected, and one much infiltrated may not contain any cancer cells. The parametrium was infected in over half the cases operated on (Pankow 46 in 67 cases. Mackenrodt 41 in 48). The glands were affected in about one-third of the cases (Barsch 11 times in 38 cases). The glands are more often carcinomatous when the parametrium is affected. Therefore even though one should feel doubtful about the removal of the glands, the parametrium alone drives us to the abdominal route. It is urged against the removal of the glands that it adds to the danger of the operation, and that it is not possible to recognise and remove all those affected; and that two-thirds of them are not involved; but the success of Döderlein and others, from whose patients carcinomatous glands were removed, the patients remaining healthy to-day, must prevent haste in declaring the removal unnecessary and dangerous. We cannot accept as certain that metastases in the glands perish, though this in the experience of some has become probable (Schauta, Mackenrodt, Petersen, &c.). The fact that the worst cases are treated abdominally, and that the abdominal operation is only in its infancy may explain the primary mortality of 18–20 per cent. The results are becoming better (Kröni 2 deaths in 47 cases; Döderlein's last 25 cases without a death, &c.). The vaginal primary mortality is about 6–8 per cent. Regarding technique. Bumm does not drain, holding that it encourages pus formation, and may kink the ureters. Author advocates the use of rubber drains instead of gauze. Injuries to neighbouring organs are not so liable by the abdominal method, but against this is the danger of necrosis of the ureters, cystitis, pyelonephritis, &c. Nothing is more difficult than to decide which cases are suited for operation. Clinically it is scarcely possible (Krönig). Author advises that perhaps in cases which clinically seem inoperable one should not operate in order not to raise the mortality too high, even at the risk of leaving a woman to her fate who might otherwise be saved. The late results can also be improved by removing the recurrent cancer if it should appear. The operation may be difficult, but has been successfully performed. A means may possibly be found

to destroy the cancer remaining after operation, or better, to help the body in bringing about its destruction. One may hope that when very few cancer cells are left a favourable opportunity may be given to remedies to act, which under other circumstances are powerless. G.

On Foreign Bodies in the Uterus.—Dr. Hellier (*Practitioner*, February, 1906) enumerates, among others, pessaries, tents, hairpins, a tin box. They are usually introduced to procure abortion, but a pessary may migrate from the vagina to the uterus, especially when introduced shortly after labour. The symptoms are those common to endometritis, subinvolution, and other pelvic ailments. The leucorrhœa is likely to be offensive. If the presence of the foreign body be unsuspected, one may become suspicious of malignant disease of the body. G.

On Ventrifixation, with Details of a Complicated Case.—Sir William J. Sinclair (*Brit. Med. Journ.*, Jan. 27th, 1905) in referring to the discussion on ventral fixation recorded in the *British Medical Journal* of December 16th, 1905, says he cannot agree with the remarks made by one speaker who held that the chief indication for the operation in addition to complicated retroflexion was the condition found in "cases of prolapse of the uterus in women at or past the menopause." In his opinion the operation was unjustifiable in these cases. Again he finds himself in disagreement with Drs. Herman and Horrocks as regards the danger of operating in cases complicated by adhesions. He holds the opinion founded upon the experience of 100 cases that the operation gives rise to little post-operative trouble and further, that a pelvis affected by peritonitis is less likely to be infected than the virgin structure. He quotes a case in which the operation was performed where numerous adhesions complicated matters, but where after history was excellent. H.

Does Diachylon Affect the Infant when it Fails to Procure Abortion?—Heelis, Jacob, and Trotman (*Brit. Med. Journ.*, February 3rd, 1906) record an interesting case under this heading. A young woman in her third pregnancy had symptoms of abortion at the third month—severe uterine and intestinal pains with vomiting and constipation. The os was patulous, but there was no bleeding. A blue line was noticed on the gums, but she denied taking anything that would have accounted for this. She remained in bed for two weeks, and after that went to full term without sickness, and was delivered of a live hydrocephalic child. The blue line by this time had disappeared. The patient then confessed to having taken pills of lead plaster—three or four daily for a week—when she found herself to be pregnant, but had desisted finding no result followed. Symptoms of poisoning did not appear till a month after. The child's head measured 16½ inches round its largest circumference. A *post-mortem* examination marked thinning of the brain, which contained a pint of fluid. A chemical examination of the liver showed the presence of lead in the proportion of 0.0002 per cent., an evidence that lead taken by the mother does reach the foetal tissues, and is eliminated very slowly. The question arises, did the lead produce the hydrocephaly? H.

Ventral Fixation of the Uterus and its Alternatives. Remarks introductory to Discussion by Ernest Herman, M.B. (*Journ. of Obstetrics and Gynecology*, January, 1905).—Having addressed a few remarks on the safety and simplicity of uncom-

plicated cases of ventral fixation, Herman said the first question for discussion was—In what cases should we advise patients not to wear a pessary but to submit to surgical treatment instead, and his views may be summarised as follows:—First, cases in which with retroflexion there is great tenderness of the body of the uterus, sacral and hypogastric pain, with intermittent dysmenorrhœa and dyspareunia; and, secondly, cases in which the uterus is fixed by adhesions in a retroverted position, and is very tender. On the other hand, in the majority of cases of retroversion, in which the uterus is not congested and the displacement only causes symptoms, because it is associated with slight descent, a pessary will give nearly complete relief, and such cases should be advised to be content with that treatment. The few of this class which fail to get relief from mechanical support should resort to surgery. Supposing, now, that relief is to be given by an operation; what operation? He discusses Alexander's operation, vaginal fixation and ventral fixation, and concludes that ventral fixation is the best mode of relieving symptoms caused by retroversion or retroflexion of the uterus, when the result of mechanical support is not satisfactory. That combined with dystrochophy, but not without it, ventral fixation is an efficient treatment of prolapse. That if the operation is properly performed, subsequent difficulty in labour need not be feared. By "properly performed" he meant that the anterior half of the *fundus uteri* is stitched to the muscle about half way between the *symphysis pubis* and the umbilicus.

F.

Embolism following Operation.—Dearborn (*Annals of Gynecology and Pediatrics*, November, 1904). The author describes thrombosis as resulting from three conditions:—First, after a prolonged or severe operation, secondly, as a result of sepsis in the wound, and, thirdly, where neither of the above conditions obtain. The thrombosis differs considerably both as to its type and liability to produce infection, according to its cause. If due to stagnation of blood, it most commonly occurs seven to ten days after operation. It is more common after operations in the pelvis. Too forcible use of retractors causing injury to large venous trunks, ligation of a vein near its entry to the main trunk, and loss of blood, the remaining blood being more easily coagulated, are given as likely causes. The most frequent cause of pulmonary embolism is thrombosis of the veins of the leg; next pelvic and abdominal operations, and parturition. The branches of the pulmonary artery supplying the lower lobe of the right lung are the most often occluded. Death may be caused absolutely suddenly by syncope, a little less suddenly by asphyxia; or in an hour or two on the first attack of asphyxia having passed off, another and another supervene, and death does not take place for a day or two. A pulmonary embolism which does not cause death too rapidly gives rise to a hæmorrhagic infarction accompanied by pleurisy. It usually commences with a rise of temperature to 102 deg., falling a little in twenty-four hours, so that it is possible that many cases of pneumonia, pleurisy, and pulmonary abscess following operation are due to emboli, and therefore when after operation the patient has an attack of pneumonia or pleurisy great care should be taken to keep her very quiet. The prospects of recovery depend on the size and nature of the embolisms and the state of the lungs. Very small non-infected emboli usually run a favourable course. In non-septic cases most of the danger of infarction is over in a fortnight; in septic cases not for six weeks or so. The essential treatment is rest, helped in some cases by morphia, strychnine and oxygen.

F.

Metrorrhagia Myopathica.—Brooke M. Anspach (*American Journal of Obstetrics*, Jan. 1906). Metrorrhagia myopathica is a form of uterine hæmorrhage independent of the usual causes of metrorrhagia, and

produced by a pathological condition of the uterine muscle. It manifests itself towards the close of the child-bearing period and does not occur in nulliparous women. If in a given case there is no new growth of any kind; if pregnancy can be excluded; if there is no adenexal visceral or general complication; if, in short, none of the usual causes of metrorrhagia obtain, the condition is, as a rule, regarded as obscure, and variously relegated to the domain of apoplexia uteri, endometritis senilis, preclimacteric bleeding, &c., &c. Apoplexia uteri presupposes arterio-sclerotic changes in the uterine arteries with an actual rupture of one of these unhealthy vessels; the author has failed to find such a condition in upwards of 300 uteri examined, and agrees with Reinecke in concluding that it alone cannot account for persistent metrorrhagia. The term senile endometritis merely means atrophy and is normal, and the symptoms referred to it arise from cystic glanular endometritis or disease of the muscularis. Preclimacteric bleeding is a specious name given to cases of metrorrhagia myopathica, which conveys no meaning, but the period of life at which the hæmorrhage occurs. It is plain, from the existence of these terms, that there is a class of cases which are not very well understood, and this class the author has designated by their chief symptom as cases of metrorrhagia myopathica, believing that the cause lies in the uterine muscle, whether it be a primary disease or a secondary lesion, the result of a general condition. What is the nature of the pathologic process in the wall of the uterus? Arterio-sclerosis of the uterine vessels was considered to be a sufficient cause. Therlhabes and Meir believe that a fibrosis of the uterine musculature leads to metrorrhagia. Pick found the elastic tissue varies in its amount and form at different periods of life and in different diseases. After the menopause the uterine vessels become diminished in calibre from a thickening of their walls, the vessels show more or less arterio-sclerotic changes, have a tendency to grouping, and there is a great increase of elastic tissue about these groups and in the external layers of the uterus. This change in the proportion of the elastic tissue is believed by Melnikow to take the place of atrophied parenchyma, be it epithelial or muscular, and furthers the mechanical internal equilibrium of the organ. In normal menstruation the endometrium plays a passive part—there is no actual rupture of vessels, but a diapedesis of the menstrual fluid through the thin-walled capillaries—the quantity of the flow being in direct relation to the pressure within the endometrial capillaries, this press in turn depending on the force of the arterial supply and the calibre of the venous channels of return. At the menstrual periods the slight contractions of the uterus narrow the venous but have little influence on the arterial channels, and in this way congestion and a resulting diapedesis are developed. It is natural then at the close of menstrual life that the muscular elements atrophy; that the intravascular area should be diminished by sclerotic changes in the vessel walls and by an increase of elastic tissue which helps to contract the vessels and takes the place of lost parenchyma. Hence a failure in the normal increase of elastic tissue or the obliterative changes of the vascular channels, or an excessive atrophy of the muscular elements, or an excessive hypertrophy of the connective tissue, might result in disturbances of the endometrial circulation and produce profuse menorrhagia or metrorrhagia.

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

A QUACK SKIN SPECIALIST.

A correspondent writes us from Bedford as follows:—"DEAR MR. EDITOR,—I fancy you will find a geographical error on the first page of your valuable journal, 'A Liverpod Skin Specialist So-called,' should, I think, read 'A Lancaster Skin Specialist So-called.' I fancy the case is one to which my attention was called, reported in last Friday's *Lancaster Observer*. The specialist is a farmer, Wolfenden, who acknowledged having treated 400 cases.—Yours truly, S. J."

CAMBRINUS.—Nutrition is the key—or at any rate the necessary foundation—of a rational therapeutic system, both in alcoholism and in drug crav. g. The overwhelming desire for further stimulant is often merely the physiological expression of tissue exhaustion and starvation. Hence the value in such cases of forced feeding and of the selection of nutritive and easily digestible foodstuffs. This line of treatment is unfortunately not of the kind taught in our medical schools.

ETONIENSIS (Folkestone).—In answer to your question we should advise you to be extremely guarded in speaking of Behring's serum to your patient. The curative powers of that remedy, it must be remembered, depend solely upon his *ipso dixit*. To announce a great medical discovery, and at the same time to defer full publication of its details is contrary to all the best traditions of Medicine. The reputation of the great German professor, nevertheless, is so illustrious and untarnished that the scientific world awaits final results with an extraordinary amount of interest and curiosity.

CHILD LIFE IN OUR MODERN CITIES.

"It is a question," writes a medical man from Huddersfield, "how far the liberty of the subject should be permitted to interfere with legislation to prevent the terrible destruction of child life by parental neglect, ignorance, and vice. There can be no reasonable doubts that the greater part of the infantile death-toll is absolutely preventable. To shrink from dealing with the problem is to shirk the plain and bounden duty imposed upon us as a nation. Moral responsibility cannot be indefinitely shirked, either by the community or by the individual."

K. B. MORTON (London).—Aneurism of the hepatic artery is of extreme rarity, and there are only a few cases recorded. In one instance the swelling ruptured into the hepatic duct. If you care to send any question in the form of a short note we shall be pleased to publish the same in this column. An answer is pretty sure to be forthcoming from some of our readers, however obscure the point thus raised may be.

W. A. S.—Cigarette smoking, especially when the smoke is inhaled or passed through the nostrils, is most baneful in excess.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 14th.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Mr. C. Johnson: The Horseless Carriage, 1885-1905.

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Meeting.

HUNTERIAN SOCIETY (Pagan's Restaurant, Great Portland Street, W.).—5.30 p.m. Hunterian Oration:—Mr. A. H. Tubby: Recent Surgical Methods for the Treatment of Certain Forms of Paralysis. 7.45 p.m. Anniversary Dinner.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. L. Cheate: Clinic (Surgical.) 5.15 p.m. Lecture: Dr. H. Campbell: Observations on Treatment.

THURSDAY, FEBRUARY 15th.

CHILDHOOD SOCIETY AND THE BRITISH CHILD STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture:—Dr. R. Milne: Conditions of Children, Physical and Mental, in Resident Schools. (Arranged by the Childhood Society.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinic (Surgical.) 5.15 p.m. Lecture:—Dr. P. Horrocks: The Use of Pessaries.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—8 p.m. Dr. M. Dockrell: Syphilis: Pustular and Tubercular (Nodular and Gummatous). (Chesterfield Lecture.)

FRIDAY, FEBRUARY 16th.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5.30 p.m. Mr. J. H. Evans: Meningocele (cases and lantern demonstration). Short Papers:—Dr.

F. J. Poynton: Jaundice in Infancy. Dr. E. C. Williams (Bristol): Splenicmegalic Biliary Obstruction. Mr. W. G. Nash Bedford: I. Alopecia Areata Neurotica; II. Renal Calculus. Dr. F. Langmead: Tuberculous Ulceration of Stomach.

EPIDEMIOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper:—Dr. C. Childs: A Study of the Typhoid Fever Epidemics in the United States Volunteer Camps in 1898.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. L. Lake: Clinic. (Ear.)

TUESDAY, FEBRUARY 20th.

THERAPEUTICAL SOCIETY (Apothecaries' Hall).—4.30 p.m. Conversation. Ladies admitted. Thomas Maben, Esq., will illustrate the Preparation of Anti-diphtheritic Serum by illuminant view. Dr. Stuart Tubby will describe Clouds and Climate. Mr. Fernandez Carr: Some Uses of High Frequency Currents.

Vacancies.

Bury Infirmary.—Senior House Surgeon. Salary £110 per annum, with board, residence, and attendance. Applications at once to Honorary Secretary, Dispensary, Knowley Street, Bury, Lancashire.

City of Winchester.—Medical Officer of Health. Salary £300 per annum. Applications to Thomas Holt, Town Clerk, Guildhall, Winchester.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to J. Parry Jones, Secretary.

London County Asylums, Banstead, Surrey, and Colney Hatch, New Southgate, N.—Junior Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 8 Waterloo Place, R.W.

Leicester Infirmary.—House Surgeon. Salary £100 per annum, with board, apartments, and washing. Applications to Harry Johnson, House Governor and Secretary.

Lincoln County Hospital.—Senior Male House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to the Secretary, 2 Bank Street, Lincoln.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £100 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant. Salary £100 per annum. Applications to the Honorary Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-on-Tyne.

Appointments.

BARWELL, HAROLD, M.B. Lond., F.R.C.S. Eng., Surgeon for Diseases of the Throat at St. George's Hospital.

BRODIE, DEBOROUGH, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S. Lond. District Medical Officer of the Tetbury (Gloucestershire) Union.

COOKE, ALFRED B., M.R.C.S. Eng., L.S.A., Consulting Surgeon to the Stroud General Hospital.

DODDS, H. B., M.D. Edin., Assistant Resident Medical Officer at the Royal National Hospital, Ventnor, Isle of Wight.

FREEMAN, W. T., M.D. Durh., F.R.C.S. Eng., Medical Officer to the Reading Prison.

GRIFFITHS, E. R., M.R.C.S., L.R.C.P. Lond., Senior Assistant Medical Officer at the Lewisham Infirmary.

HAFWORTH, F. ARTHUR, M.B., B.O. Cantab., House Surgeon at the Derbyshire Royal Infirmary.

MCNEILL, JOSEPH JAMES, L.R.C.S. and P. Irell., Medical Officer of Rosguill Dispensary District, Carrigart, co. Donegal.

NEWMAN, ERNEST L., M.B. Syd., House Surgeon at the North-Eastern Hospital for Children, Haekey Road, Bethnal Green, E.

PETERKIN, G., M.D. Edin., D.P.H., Certifying Surgeon under the Factory and Workshop Act for the Forfar District of the county of Forfar.

ROBERTS, ADELINA MARY, M.D., B.S. Lond., Medical Registrar at the Royal Free Hospital, London.

ROBERTS, E. J., M.R.C.S., L.R.C.P. Lond., House Physician at the Derbyshire Royal Infirmary.

WILMOT, T. J. T., M.B., Ch B., B.A.O. Dub., House Surgeon at the Derbyshire Royal Infirmary.

Births.

MARJORIBANKS.—On Feb. 3rd, at 562 Green Lanes, Haringey, London, to Dr. and Mrs. Robert Bruce Marjoribanks a daughter.

MORROW.—On Feb. 8th, at Bush Hill Park, Enfield, the wife of Ringland Morrow, M.B., of a son.

Marriages.

ARMSTRONG—CRUISE.—On Feb. 10th, at St. James' Church, Spanish Place, London, Edmund C. R. Armstrong, eldest son of the late Captain Andrew Armstrong, 2nd Queen's Royal, to Mary Frances, second daughter of Sir Francis Cruise, M.D., B.L.S.G.S., Honorary Physician-in-Ordinary to His Majesty in Ireland.

CREE—KENT.—On Feb. 8th, at the Parish Church, Godalming, Surrey, John William CREE, of the Inner Temple, eldest son of John Cave CREE, of Godalming, late of Calcutta, to Ada Mary, widow of Herbert Arthur Kent, M.R.C.S. Eng., L.R.C.P. Lond., of Ringwood, Hants.

Deaths.

WOOD.—On Feb. 8th, at 12 Lewes Crescent, Brighton, Frederick Wood, F.R.C.S. Eng., in his 87th year.

THE MEDICAL PRESS AND CIRCULAR.

NOTES AND COMMENTS.

The London School of Clinical Medicine.

ALTHOUGH a somewhat late arrival, the London School of Clinical Medicine shows signs of lustiness that augur well for its future career.

Of all places in the Kingdom, the Metropolis is the one *par excellence* for post-graduate teaching. It is, from the very nature of things, the home of great teachers and great masters of medicine and surgery. Where the provinces reckon their stars by the half dozen, London numbers them by the score. That result is clearly the outcome of the unrivalled field for practise afforded in the huge city which forms the centre not only of the United Kingdom, but also of the Colonies, and of a great part of the civilised globe. So it is fitting that a strong effort should be made to provide a post-graduate school worthy of the name and fame of London medical workers and teachers. We venture to think that object has been more than achieved by the London School of Clinical Medicine, to which we cordially wish a long and prosperous career.

Waiting for the Verdict.

FROM New York we hear of another of those tragedies which the medical world is only too painfully familiar. While inoculating a rabbit with anthrax in his laboratory a sudden movement of the animal caused Professor Meyer, of Tulane University, to plunge the point of the syringe into his own fingers. With prompt and thorough surgical treatment there should be a good prospect of averting any serious consequences. However, journalists on both sides of the Atlantic have seized upon the sensational side of the incident. In a London newspaper, for instance, the Professor is pictured as waiting for ten terrible days to know whether the accident will or will not cost him his life. How the ten days limit is arrived at we hardly know. If the inoculation be not aborted the characteristic pustule, well termed "malignant," will appear in two or three days, and if it is going to be fatal, will probably do so within five or eight days. Not that the gravity of the accident should be under-rated. The risks are indeed terrible, and anthrax has already claimed various victims amongst medical investigators.

THE curse of water-borne typhoid fever probably becomes in most cases sooner or later a blessing in disguise. The havoc wrought by a sudden outburst of that terribly fatal malady enforces a never-

fading lesson upon the most careless and ignorant community. Last year Lincoln paid the penalty of its neglect in an enormous loss of lives and of commercial prosperity. This year its citizens are paying huge sums in compensation to the victims and friends of the victims of the typhoid-laden water supplied to them by the civic authorities, in spite of twenty years of official warning and condemnation. This costly popular education, however, is not likely to end in the present generation. The medical officer of the Gainsborough Rural District Council, for instance, recently reporting on an outbreak of typhoid in Trentside villages, said the people had disregarded his warnings against drinking water taken direct from the Trent. The people replied that they had drunk the water all their lives. The impression amongst them was that the Almighty sent typhoid and such things, and that any precaution on their part was useless. Well may Fleet Street head this item of news "Kismet."

Bogus Death Certificates.

TRUTH to say, a wholesome spirit of activity appears to have invaded the country, and news of quack prosecutions are pouring in upon every hand. An unqualified man who has been posing as a qualified practitioner in Liverpool for some years past was charged last week on six several informations for forging certificates of death. His real name was Jolly, but for the purposes of practice he called himself Dr. Joseph Fitzgerald, L.K.Q.C.P.I. The prosecution which was instituted by the Registrar-General resulted in a fine of £40 and £10 costs. If the Registrar-General would take wider cognisance of cases of this kind, the career of a large number of fraudulent adventurers would speedily be brought to an end. Why should not the General Medical Council bring pressure upon the Registrar-General and upon other agencies likely to curtail irregular practice? But the Council does not profess to be the champion of the medical profession.

A Herbalist caught by the Excise.

THERE are more ways than one of cooking a goose. It has been often pointed out in our columns that the defects of the Medical Acts can be compensated by calling in the aid of other existing laws. The Registrars of deaths and births, for example, could hamper the trade of irregular practitioners to an almost incalculable extent, especially if they were in touch with the

coroners. The police, needless to remark, could soon put an end to quack practice simply by prosecuting offenders for obtaining money under false pretences. In Liverpool last week the Excise showed their power in the same direction by prosecuting a herbalist for selling without a license "anti-stomachic drops" and other remedies containing methylated spirits. The defendant was fined £2 for each of several specified offences, and £5 5s. costs. The result of the prosecution should encourage our Defence Societies, as it adds another to the various indirect methods by which these pests of society may be brought to book.

**Bristol Bogus
"Doctor"
Fined.**

IN Bristol a notorious electrical quack has been laid by the heels, thanks to that champion of our profession, the Medical Defence Union. From the evidence, it appears that he held an unrecognised American diploma, and managed an Institute where X-ray, sinusoidal, high frequency, and many other forms of electrical treatment were obtainable. All this he might have done quite safely in the present ridiculous state of British law as regards quackery, had he not called himself "Doctor." Upon that score he was convicted by the magistrates and fined £10, together with £5 costs. Obviously the loss of £15 now and then will not put a stop to so lucrative a business as that of an unqualified medical electrician. Moreover, the offender in question is likely in future to be content with calling himself plain Frank Lee, and thereby avoid expensive and ornamental titles. One significant point brought out in the course of the trial was that the precious institute belonged to a clergyman and a Justice of the Peace. In this case the Bishop of the Diocese would, in our opinion, be justified in depriving the owner of a bogus medical concern of his cure, and the Lord Chancellor in removing the other from his magistracy. Will the Medical Defence Union kindly inquire into the possibility of thus following up the victory?

**The Election
of Direct
Representative
for Ireland.**

IN accordance with the request of Sir William Thomson, a recount and a scrutiny of the votes cast at the recent election took place during the past week. During the scrutiny a number of votes were objected to on the ground that the papers were improperly filled, and these were submitted at the close of the court to a meeting of the Irish branch of the Medical Council. The result of the proceedings was that Dr. Leonard Kidd was declared to have obtained 909 votes and Sir William Thomson 901. Dr. Kidd's majority was thus increased to eight, instead of four as declared after the first count. The recount will do good, if it serves to direct the attention of medical men to the necessity for adhering to the letter of the rules given for filling up the voting forms. If these rules had been followed in every case, it is unlikely that a recount would have been required, and thus a consider-

able amount of expense would have been saved—expense which can be none too well borne by the exchequer of the Irish branch.

LEADING ARTICLE.

MR. TROUTBECK'S SENSE OF "DUTY."

MR. CORONER TROUTBECK'S general distrust of the medical profession appears to be equalled only by his pathetic faith in the findings of his pathologist, Dr. Freyberger. The latter, in a recent inquest case, with rare skill and scientific insight detected perforation of a stomach as the result of a chronic tubercular ulcer. To that difficult technical observation he added the further brilliant inference that death was due to "sudden failure of the heart, accelerated by hæmorrhage of the lungs, while suffering from general blood-poisoning, the result of rupture of a chronic ulcer." Why an "expert" pathologist is needed at high fees to tell us this tangled tale is known possibly to Mr. Troutbeck, but to average plain medical men it is a thing past understanding. The unfortunate subject of the inquest was an inmate of Wandsworth Workhouse, who died within two days of the receipt of an injury. The master of the institution in question stated that deceased had met with an accident and was struck in the groin one Sunday evening while carrying a bag. He telephoned to the medical officer, who, in answer, ordered hot fomentations and an opium pill, and the patient at twelve next day. Monday the man vomited blood and died. The medical officer's story is that he telephoned at nine o'clock on Sunday morning, and was told the patient was better. He saw him at noon, and formed a tentative diagnosis of peritonitis, but at the patient's request did not remove him to the infirmary, especially as he thought it best to avoid rough movements. In his opinion, the blood had little to do with the death. Dr. Freyberger, on the other hand, was of opinion that an early diagnosis would have permitted an operation whereby life might have been saved. Where is this sort of thing to stop? The "expert" pathologist—if we are to accept the newspaper reports found that the vomited blood came from the lungs. Not content with the remarkable coincidence of hæmoptysis with ruptured gastric ulcer, he has next plunged into the difficult field of operative surgery. A pathologist is about the last person in the world one would turn to for advice on the vexed question of when it is justifiable to operate upon perforations of the stomach and intestine. He would be a bold surgeon who would perform a gastric section if called in to a man of 38 suffering from chronic tubercular ulcer of the stomach. It is to be presumed, moreover, that, as Dr. Freyberger reported hæmorrhage from the lungs, those organs were also more or less seriously involved in the tubercular process. Yet Dr. Freyberger has no hesitation in advancing a general

proposition that an operation might have saved the patient's life, regardless of the grave injury he is thereby doing to the medical man in attendance before death. Dr. Freyberger, be it noted, founded his views, which from internal evidence appear rash and untrustworthy in the extreme, upon an examination of the body after death. Any stick is good enough, however, for Mr. Coroner Troutbeck when he wishes to attack the medical profession either generally or individually. In the present case we regret to say that the stick has been placed in his hand by Dr. Freyberger, as we firmly believe, on grounds that reflect considerably on the soundness of his professional skill and judgment. There can be no hesitation in saying this, because Dr. Freyberger by an *ex cathedra* declaration in the Coroner's Court, where there is no chance of discussing or of controverting his utterances of opinion, is dealing a most injurious blow at the reputation of a Poor Law Medical Officer. If the authorities of the Local Government Board are jealous of the credit of its officers they will insist upon a full inquiry into this unhappy case. It seems possible that the opportunity of investigation will possibly be afforded them by Mr. Troutbeck, who gravely informed the jury that the telephonic messages opened up an entirely new situation, which he would deem it his duty to send for inquiry either to the Guardians or the Local Government Board. *Quem deus vult perdere, prius dementat.* Mr. Troutbeck always has the courage of his opinions, but we can hardly think him unwise enough to refer this case to the Whitehall authorities. If he does we most heartily express a wish that we might be there to see. There must be bounds settled somewhere to such arrogant indifference to the rights and traditions of a great profession as that displayed by Mr. Troutbeck and his henchman pathologist.

NOTES ON CURRENT TOPICS.

Secret Commission and the Veedee Vibrator.

We have received during the past week a copy of a circular which is being sent round to the medical profession by an individual of the name of H. E. Garratt, who proposes to send on free trial an instrument which he terms the "Veedee Vibrator." With the implement itself we have no concern, save to say that it is stated by its proprietor to cure rheumatism, gout, sciatica, constipation, liver, kidney, and stomach trouble, nervous debility, etc., etc., and that "Dr. J. Mortimer Granville, the great specialist and consultant, who studied the subject deeper and more practically, probably, than any other man," is, by an ingenious twist of the King's English, made to recommend its use. *En passant*, we may say that this gentleman's name does not appear on the *Medical Register*, in spite of the fact that he is "a great specialist and consultant." The matter with which we are concerned is the "special note" which appears on a slip marked "private

and confidential" appended to the circular letter. This note runs as follows:—"Any medical man desiring to prescribe the Veedee Vibrator and Attachments may instruct me to send to the patient direct and charge to the patient at list prices. In all such cases I would, immediately I receive the patient's remittance, send 25 per cent. to the medical man as his profit." This announcement, for sheer impudence, has had little to beat it since a maker of canvas Turkish baths addressed a somewhat similar circular to medical men. We confidently believe that there are but very few in our profession at the present day, who would so lower their professional status as to accept secret commissions in so gross a form. We regret that the Bill which was brought forward by the late Lord Chancellor with the object of preventing the giving of such commissions was not passed, and that this man cannot be brought within reach of the law, and we trust that our lay contemporaries will bring this paragraph to the notice of the general public.

A Delayed Autopsy.

In but few cases has it been possible to make an autopsy on a body a century dead, and to be able to discover therein pathological conditions sufficient to account for death. This has been done, however, in the case of Paul Jones, the famous American seaman, who died in Paris in 1792, and whose body was examined only last year. A full account of the recovery and examination of the body is given in the *Revue d'Ecole d'Anthropologie* (tome VIII.) and reproduced in the current number of the *Edinburgh Medical Journal*. The body had been packed in straw, soaked in some alcoholic preservative fluid, and enclosed in a leaden coffin. It was found, on opening the coffin, to be in an excellent state of preservation, in appearance like a mummy, but with the soft parts still soft. The resemblance to known portraits and descriptions, the colour of the face, the accurate agreement of measurements, and the initials "P" and "J" on the linen shirt were sufficient to afford identification of the body. But further evidence was forthcoming. Paul Jones was known to have suffered for some time before death from disease of the left lung, and in his last illness general dropsy was superadded. There was no doubt, on examining the lungs last year, of the presence of pleurisy, particularly on the left side, and patches suggestive of broncho-pneumonia were also discovered. The kidneys were small and suggested the presence of interstitial nephritis. The organs were submitted to Professor Corniel for histological examination, and to his astonishment, the results obtained were practically identical with those which might have been afforded by the organs at an ordinary *post-mortem* examination. In the lungs were typical patches of broncho-pneumonia, and the kidneys showed the changes of advanced interstitial nephritis. The liver was healthy, and afforded beautiful sections. A curious fact is that on the skin,

viscera, and other parts, were found small white firm masses consisting of crystals of tyrosin. The whole story is one of the strangest records in the history of pathological work.

"Sei-i-Kwai Medical Journal."

OUR contemporary, the *Sei-i-Kwai Medical Journal*, the official organ of Sei-i-Kwai, or Society for the Advancement of Medical Science in Japan, is always a welcome addition to the medical monthlies that come under our notice. Valuable as it is from the point of view of professional merit, it is perhaps more so as showing the intimate connection between Anglo-Saxon and Japanese medicine, a connection which was organic in its origin and which we hope will remain vital in its development. From the December number which lies before us we learn many interesting facts. To those who claim the Japanese as fellow-vegetarians it may be of interest to know that the daily ration of the sailor contains, besides biscuit (or bread), rice, barley, vegetables, sugar, and tea, five ounces of preserved or seven ounces of fresh meat, and five ounces of preserved or fresh fish. The advantage obtained by including proteid foods in the dietary of the Navy was long ago demonstrated by Takaki, and although his reasoning is denied by some authorities of the present day, the fact remains that after the introduction of his scale beri-beri disappeared from the Navy, which up to that time had been annually decimated by it.

Sleeping on the Roof.

As our city populations grow more dense so the value of land rises. Of recent years a great deal has been done to multiply the housing room of every given site by building skywards. But the people multiply at racing pace and the limit of added house-room is speedily exhausted. The only alternative is to migrate to green fields and open country, but even there the price of land is for the most part prohibitive. Under these circumstances it is no wonder that social economists have turned their attention to the roofs. One London hotel, at any rate, boasts of a garden on the roof-top. A generation or two hence it may be that all city dwellings will have a roof space laid out for recreation, for gardening, games, exercise or what not. In South London there are some working-men's blocks of tenements with large flat roof-tops that are used by the children for a playground, by their elders for recreation and vicariously as a drying-ground for laundry purposes. In America a society craze has sprung up for simple life on the house-top. The medical men of New York are said to be denouncing the fashion as highly dangerous, although a few cures have been reported therefrom in the case of consumptive patients. The cult of the house-top is clearly capable of much development. It would be easy enough to provide shelters thereon against the rigours and eccentricities of our own insular climate.

Anthrax and its Prevention.

THE recent case of anthrax at Bradford has called attention once more to this deadly but absolutely preventable disease. Many regulations have been enforced by legislation, but they miss the vital point as to the nature of the disinfectants to be used. Clearly the destruction of the anthrax bacillus and its spores must depend on the efficiency of the methods of sterilisation. It is interesting, therefore, to learn that Professor Klein has completed an important series of experiments in the sterilisation of anthrax spores, the result of which proves that Cyllin when diluted in the proportion of 1 in 50 is capable of destroying the most virulent strains when exposed for a period of 45 minutes. The experiments were first conducted with 60 minutes exposures, and were later repeated with equal success, as stated, with exposures of 45 minutes. The spores employed by Professor Klein in carrying out these experiments were isolated from a recently fatal case of "Wool-Sorters' Disease." Of course, it is not for a moment suggested that good results could not be obtained with other antiseptics. Dr. Klein's experiments, however, seem to us so direct and conclusive as to deserve special notice.

Instruction in Medical Ethics.

THE medical curriculum through which the unfortunate student of to-day has to wade to the practice of his profession is already not so much over-burdened as crushed by the weight of its ponderosity. The plan of teaching students to be medical factotums is likely soon to perish through obvious futility, and then it may be hoped that a capable practitioner rather than an inverted encyclopædia will be the aim of the efforts of the examining boards. One may well hesitate, in awaiting that day, to recommend any further subject for instruction; but in so far as a practitioner rather than a pedagogue is sought, so should certain matters of immediate practical moment replace some of the theoretical absurdities of the present. In any re-modelling that may be done now or hereafter a place should be found for the teaching of medical ethics, and, what is even more important, the implantation of a true professional spirit in the physician and surgeon of to-morrow. Now that the days of apprenticeship have gone, never, probably, to be recalled, it is the more incumbent on teachers to make students feel that when they leave the hospital they become units of a great profession having high obligations to its individual members, as well as to the public. Such an idea is foreign to much of the teaching and even the practice of many medical schools, and the result in want of loyalty or want of good taste is plainly visible in not a few young practitioners. The weight of these obligations is only borne in on them by time and experience, and in the meanwhile their own careers may be blighted and much professional misunderstanding and bad feeling have been caused. *An esprit de*

corps such as exists in the public services should be early instilled into those seeking to enter the profession and maintained, once they are in it, as a priceless possession.

Copper Sulphate and Drinking Water.

IN our last number we published a letter from Dr. Howard-Jones, Medical Officer of Health for Newport, Mon., in which he took exception to some remarks of ours which appeared in THE MEDICAL PRESS AND CIRCULAR of January 17th, with regard to the sterilisation of drinking-water by means of copper sulphate. We had said that we should have to be strongly persuaded of the necessity of employing this disinfectant before recommending its adoption for the sterilisation of reservoirs, because of the danger, which we admitted was an unknown quantity, of giving rise to chronic copper poisoning among those who drank the water habitually. Dr. Howard-Jones thinks that our remarks are likely to prejudice water authorities and the public against the method, and he maintains that the copper in solution can all be precipitated in the reservoir by the addition of lime to the water containing it. Therefore, he writes, the public need have no fear "if the process is carried out under the supervision of a competent chemist." If, instead of using the word "prejudice," Dr. Howard-Jones had said of our remarks that they were calculated to make water authorities and the public take great heed before committing themselves in the matter, we should have had no reason to find fault with his criticism. In our note we adduced a specific case, that at Manila, where the process had failed to fulfil expectations, through the operation of some local cause or causes unknown. We do say that it is a serious thing to embark on the impregnation of the public water supplies with a metallic poison until long and extended experience has revealed all the factors, probable and possible, which enter into the process of sterilisation or precipitation, and which may upset the most exact and scientific calculations. The use of copper sulphate on emergency may be justifiable and even valuable, but we should rue the day when, instead of collecting water from unimpeachable sources and conveying it by unimpeachable means, it was deemed necessary to use copper sulphate as a routine measure in the purification of the normal water supply of towns.

A Health Conscience

A GOOD deal has been heard during the last few years about the cultivation of that psychological abstraction—a health conscience. To call a thing an abstraction is not to deny it a being, and even a function, but only to draw attention to its intangibility. Dr. Clouston, we notice, has been urging its evocation in the columns of our contemporary, the *Spectator*, and he thinks that the conviction of sin against health is growing. We believe this is so, to a certain extent at all events, but we doubt if the conscience is growing either

at the proper rate or in the proper direction. We take it that conscience is an educated sense of the fitness of things, moral, religious, or hygienic, as the case may be, and that given a nature capable of response and given a training of an appropriate character, a conscience, or consciousness of right and wrong, may be created where it only potentially existed before. Can it be maintained, first that all men are capable of producing this conscience, and, secondly, that the training that is going on is of an appropriate character? Probably most, if not all, civilised beings have the constituents of a health conscience in their composition, but we can hardly believe that it is being properly evolved. The necessary training in the health, as in the moral sphere, is largely one of example, and the example of healthiness is one hardly set by the bulk of the nation. Moreover, in so far as precept is concerned, our health teachers are far too often, like the men who lose most money at Monte Carlo, men with systems with this one diet, with that one drink, and with the other exercise. If a health-conscience is to become a general possession, our health-teachers must be men who are of the world as well as in it and follow the ways of righteousness while living the ordinary lives of ordinary men, yet without sin. Food-worshippers, teetotallers, and Sandow-exercisers may attract schools, but they will not convert the world.

PERSONAL.

A GOOD many Colonial *conféres* are in England just now; among the arrivals last week were Dr. Adam Jameson of the Transvaal, brother to the Premier, and Dr. H. Lorans, Chief Sanitary Officer of Mauritius.

Two important Colonial appointments have just been filled. Dr. W. A. B. Hutton has obtained the post of Government Medical Officer to the East Coast of Vancouver, and Dr. L. B. Barbeau becomes Director of the Health Department of Mauritius.

SURGEON-GENERAL J. P. WALKER, M.D., who died last week at the age of eighty-six, was the oldest living member of the Indian Medical Service. He was through the whole of the Mutiny, and retired from the service thirty years ago.

WE congratulate Dr. Reginald Eager of Northwoods Asylum, Winterbourne, on the courage displayed in entrapping a would-be blackmailer and prosecuting him last Friday at the Bristol Assizes. Dr. Eager had the satisfaction of hearing his conduct publicly approved by the Judge, and the scoundrel sentenced to five years penal servitude.

PROFESSOR ROBERT KOCH has been commissioned by the Imperial Government to proceed again to East Africa, in order to resume his investigations into the causes of the sleeping sickness.

ON the 16th inst., the Lady Mayoress of Sheffield unveiled a portrait of Dr. H. C. Sorby at the local University in commemoration of fifty years distinguished scientific work connected with that town.

THE venue of the appeal in the Cardiff trial for damages against Dr. Skryme and Mr. Lynn Thomas has been removed to London.

A CLINICAL LECTURE ON HEMIPLEGIA.

Delivered at the North-East London Post-Graduate College on January 25th, 1906.

By ARTHUR WHITING, M.D., F.R.C.P.,

Assistant Physician to the Tottenham Hospital, N., and the Mount Vernon Hospital for Consumption and Diseases of the Chest, and Dean of the College.

PARALYSIS of one side of the body, face, arm, and leg, described in medical terms as hemiplegia, and popularly as a "stroke," is not, as you know, a disease, but a sign of disease. It is proposed here rather to consider hemiplegia in relation to the nature of its cause than to discuss the well-known characteristics of this form of paralysis.

CAUSES OF HEMIPLEGIA.

Although there is only one anatomical explanation of hemiplegia, namely, a lesion of the motor tract in one side of the cerebrum above the face centre in the pons, there are several common pathological causes, and the importance of recognising the nature of these causes is evidenced by the difference in the treatment of the patient, according to the difference in the cause. The main proximate pathological causes of hemiplegia are thrombosis, embolism, hæmorrhage and tumour in the brain, and with the unrecognised changes underlying the condition known as functional or hysterical paralysis.

Clinically, the influence of one or other of these proximate pathological causes is fairly definitely indicated by the character of the onset of the paralysis. Speaking generally, it may be said that the hemiplegia which is due to cerebral tumour is slow in its development, and by that I mean a space of weeks or months as a rule elapses between the first indication of the paralysis and its full development. The hemiplegia of cerebral hæmorrhage is usually sudden in its onset, a matter of minutes or even seconds; that of embolism is also sudden, but probably less sudden than in the hæmorrhagic cases; and that of thrombosis is neither sudden nor slow, but might be said to be deliberate, taking, it may be, hours for its full development.

CLINICAL ACCOMPANIMENTS OF HEMIPLEGIA.

In the case of hemiplegia due to cerebral tumour, there are usually the general signs of increased intracranial pressure, headache, purposeless vomiting, double optic neuritis, and often fits limited to one side or beginning on one side and extending to the other, and with or without loss of consciousness. In the earlier stages the hemiplegia is usually more profound for a while after the fits. Although as a rule the onset of the hemiplegia from this cause is slow, yet sometimes it is sudden, possibly from the occurrence of hæmorrhage into a slowly growing tumour.

Before a hemiplegia due to thrombosis there are sometimes premonitory subjective phenomena, e.g., attacks of tingling limited to the face, arm, trunk, and leg of one side. The attack comes on as a rule during rest and especially when the heart is slackened during sleep. As a rule there is no loss of consciousness. In addition to the weak circulation, there is usually evidence of arterial disease leading to roughening of their inner wall. In young men the usual form of arterial change is syphilitic end-arteritis; in older people it is usually atheroma associated or not with chronic nephritis. In young women the predisposing constitutional state is usually anæmia.

The embolic hemiplegia may or may not be associated with loss of consciousness, according to my own experience it more commonly is. There is evidence in the majority of cases of cardiac valvular disease, more especially mitral stenosis, but often aortic valvular disease. There may be other evidence of embolism elsewhere, of which the most picturesque is that of embolism of the central artery of the retina. There is often some history of precedent and unaccustomed exertion.

The hemiplegia due to hæmorrhage practically always comes on during exertion or excitement. The specimen from a case of cerebral hæmorrhage I now show you was from a woman who fell down unconscious as she was walking from church last Sunday morning. It is the almost invariable rule for consciousness to be lost in this group of cases. On examination there will, as a rule, be found a hypertrophied and violently acting heart, an accentuated aortic second sound, rigid arteries, and other evidence of renal cirrhosis.

CLINICAL VARIETIES OF HEMIPLEGIA.

The division of cases of hemiplegia according as they are left or right sided, or alternate or double sided, is a mechanical subdivision, and one needing but little attention. As regards the left-sided cases, I would merely remind you that the functional cases are more often of this kind, and that it is with right-sided hemiplegia in right-handed persons that a true aphasia occurs. The importance of a crossed or alternate hemiplegia is solely derived from the indication afforded of the position of the lesion; for example, when the third nerve is paralysed on one side and the face, arm, and leg on the other side, it is at once clear that the lesion is in the neighbourhood of the crus cerebri, the third nerve being injured after it has decussated and the other motor fibres before. Similarly, if the face is paralysed on one side and the arm and leg on the other, our knowledge that the decussation of the seventh nerve fibres is about the middle of the pons allows us to decide at once that the lesion is in the pons below that level. Double hemiplegia, which is chiefly seen in thrombotic cases, gives a strongly marked clinical picture from the circumstance that the difference between the escape of the automatic and the extreme interference with the highly specialised movements, as seen in the one-sided cases, no longer holds. The leg does not escape now as compared with the arm, and walking becomes impossible. The muscles of deglutition and of articulation are now greatly involved, and, what is practically never seen in a really one-sided hemiplegia, the sphincters participate in the paralysis. So pronounced are the bulbar symptoms that the condition is often called pseudo-bulbar paralysis, but it may readily be distinguished from the labio-glossolaryngeal paralysis of nuclear origin by there being no atrophy, e.g., of the tongue and no degree of the reaction of degeneration.

CLINICAL CHARACTERS OF HEMIPLEGIA.

By way of illustration of the clinical features of the hemiplegic state, I hope to show you a few typical cases. There are, however, a few clinical points I would shortly refer to. As regards the face, the paralysis, as you know, generally leaves untouched the upper facial muscles for the reason that they are more automatic and more bilaterally supplied than the lower. The tongue, in a majority of cases, but not a large majority, deviates to the paralysed side, because the genio-hyoglossus muscle of the sound side pushes out that side of the tip of the tongue more vigorously than the other. A true aphasia is not infrequently seen in right hemiplegia in right-handed persons, but in left hemiplegia the conversation of the patient may be unintelligible. This is due not to defect in the mechanism of speech processes, but to clumsy articulation.

In regard to the limbs, the extremities with their more specialised movements are more paralysed than their proximal parts, shoulder and particularly hip. As regards the trunk, it will be remembered that while most of the pyramidal fibres decussate in the medulla

to form the direct pyramidal tract, a few pass down the cord on the same side, and these are believed to supply the deep muscles of the back. At any rate, with weakness, e.g., of the right arm, there is also weakness of these muscles on the left side. The physiological correlation of the muscles of the limb and back is well illustrated by the muscular contraction required for, say, carrying a pail of water.

In regard to the *anæsthesia*, it is a hemianæsthesia, but not so complete or absolute as in functional hemiplegia (and I may here say that I have refrained from taking into account the cases of functional hemiplegia to-day because I so recently had an opportunity of discussing that subject with you). The stress of the organic hemianæsthesia falls mainly on the hand and foot. It fades away towards the trunk, and the limit in the middle line is not sharply bound by that line as in the functional cases, but overlaps it both in front and behind.

In regard to the *reflexes*, the general rule is that the deep reflexes are increased, accompanied by ankle clonus and the extensor plantar reflex, and the superficial reflexes are diminished.

In hemiplegia of one side the *sphincters* and other automatically acting muscles, as those of deglutition are not affected.

In regard to the *special sense*, the characteristic change which is itself usually associated with hemianæsthesia is hemianopsia.

TREATMENT OF HEMIPLEGIA.

The treatment of hemiplegia resolves itself into two sets of measures, the one to meet the attack, the other to prevent its recurrence. When it is due to a new growth in the brain, there is no treatment of the paralysis except perhaps in syphilitic cases, where vigorous antisiphilitic measures should be tried. The treatment of the case is essentially surgical: opening the skull, it may be, to relieve or stop the headache and vomiting, to save the vision from destruction by a consecutive atrophy, and to obviate the tendency to sudden death, or, a step further, attempting to excise the tumour, but in this case there will obviously be no amelioration of the paralysis itself; it is, indeed, certain to be made worse if that be possible.

The treatment of an apoplexy due to *hæmorrhage* is almost directly the opposite of that due to thrombosis. In the hæmorrhagic case the indication is by all means to lower the blood pressure and to promote clotting in the ruptured vessel. Hence the use of free purgation, and possibly of venesection, and the avoidance of all stimulation of the heart. The after-treatment, apart from the effort to minimise the effects of the paralysis, is largely one of quieting the circulation and combating the constitutional state manifested by, and partly due to, the cirrhosis of the kidneys often present. There is little, if any hope of influencing directly arterial degeneration, the aim is to control the blood pressure.

The treatment in the *thrombotic* cases is directed to an improvement of the circulation and the prevention as far as may be of clotting. To this end stimulants may be cautiously given, ammonia, which is believed to have an influence in both these directions, being probably the best; but alcohol in moderate quantities may be given; nitrites, say doses of 1-100th mm. of nitro-glycerine, are probably of value in dilating the arterioles and thus promoting circulation; to act on the heart small doses of digitalis, strophanthus, sparteine, or caffeine are of value. Purgation, if at all, must be gentle, and venesection is inadmissible.

In treating the constitutional state with the object of preventing, if possible, another attack, everything that would favour arterial degeneration, and therefore roughening of the interior of the vessels must be avoided; much nitrogenous food, the free use of alcohol, and anything that favours what is known as the gouty state should be interdicted. The heart's action should be kept as far as may be quiet, regular, and fairly strong.

In the syphilitic cases, I am firmly convinced of the protracted and intermittent use of iodides and mercury

not with the hope of materially influencing the already softened area, but with the object of improving the arterial disease and thus preventing a succession of attacks.

In the treatment of *embolic* cases the chief aim is to promote a regular cardiac action, for it is probable that a heart contracting first weakly and then strongly, is more likely to encourage the detachment of vegetation from its valves. In all cases some weeks' rest in bed is strongly indicated.

As to the *treatment of the attack* of paralysis, the tendency is to spontaneous improvement. Nearly always it may be promised that recovery of the leg will occur sufficient to allow of walking. What cannot be promised is that the delicate movements of the fingers will be regained. The exceptional cases in which walking is not regained, or only very imperfectly, are usually those with hemianæsthesia, the reason being that the leg fibres are the most posterior of the motor fibres adjacent to the sensory fibres in the internal capsule and are, therefore, more profoundly injured by a posterior lesion. If the lesion be anterior or in the middle of the motor fibres in the internal capsule, the leg recovers first, although its fibres may be as much damaged as the arm fibres, because the leg movements are more automatic and are probably more richly supplied from the healthy side of the brain.

Perhaps the chief aim, although the hope is not great, is to diminish the rigidity; but very gentle Faradism may be applied to the paralysed muscles, especially to those normally weaker, as the extensors of the wrist and fingers. Passive movements, the breaking down of adhesions, and gentle massage to the especially weak muscles may be tried with circumspection.

It is probable that a second attack in a majority of the cases will follow the first, and the treatment of "hemiplegia" is, therefore, essentially prevention of its proximate causes by keeping in abeyance its ultimate causes.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of the journal. The *Lecture* in next week's will be by William J. Dargan, M.D., Physician to St. Vincent's Hospital, Dublin, on a case of "Secretary Neurosis of the Stomach."

ORIGINAL PAPERS.

INAUGURAL ADDRESS ON

CARCINOMA OF THE UTERUS.*

By F. BOWREMAN JESSETT, F.R.C.S.,

President of the British Gynaecological Society.

IN my address this evening I do not think I can choose a better subject than that to which I have for a considerable number of years paid especial attention—I refer to Cancer of the Uterus. It is more than twenty years since I first attempted to deal with this terrible disease by the removal of the entire organ, which up to that time had not been attended with any amount of success. To Dr. Purcell is due the credit of having been the first surgeon in this country to carry the operation to a successful issue, at which operation I was present and was much struck by its feasibility. My first few cases, however, were attended with such disastrous results that I determined, excepting in very suitable cases, not to attempt it again, and it was not until the year 1892 that I again met with a case which I considered favourable; the patient on whom I operated made an excellent recovery, and since then I have operated on over 200 cases.

Diagnosis.—We are beset with difficulties in the selection of suitable cases for operation, as we rarely meet with a case in its early stage. At the Cancer Hospital a very small percentage of cases present themselves in which any operation would be

* Read before the Society, February 8th, 1906.

justifiable. Now one would think that cancer of the uterus should be as readily diagnosed as cancer of any other portion of the body, and no doubt it would be if patients presented themselves for examination early enough, and if the family medical man would insist upon a vaginal examination when any of his patients consulted him for vaginal discharge or any irregularity connected with menstruation. Unfortunately, however, women through delicacy rarely do consult their medical attendant for these troubles until the discharges become offensive or blood-stained, or they suffer inconvenience or pain from the presence of the disease; even then, I regret to say, they are too often treated by some astringent vaginal douche. Had patients suffering from advanced uterine cancer presented themselves early for examination, I venture to say in many cases they could have been freed from their disease and spared for many years to come.

Sir Halliday Croom has drawn attention to the frequency with which malignant disease begins, or, at all events, progresses after labour. It is not at all uncommon to meet with women who have recently been confined or aborted who have complained of hæmorrhage for weeks afterwards, and on examination malignant disease is discovered. American physicians insist upon the importance of periodical examinations after confinements so as to note the condition and appearances of the parts. Kelly goes so far as to say that all women aged over 40, with a laceration, should be yearly examined with this view.

CANCER OF THE VAGINAL PORTION OF THE UTERUS.

If examination were methodically carried out there would be little difficulty in recognising carcinoma of the vaginal portion of the uterus and os; although not uncommonly erosion and a lacerated os uteri, accompanied by chronic inflammatory mischief, often closely resemble malignant disease. If, however, the eroded or ulcerated surfaces readily bleeds and the os uteri is nodular and uneven, suspicion should be aroused and a small wedge-shaped piece should be excised and submitted to the pathologist. If it is pronounced to be malignant, operation, by high amputation of the os and cervix, as recommended by Sir John Williams and others, or vaginal hysterectomy, should be at once practised, and in these cases I am sure a large proportion of women could be cured.

CANCER OF THE BODY OF THE UTERUS.

What is true as regards the diagnosis of the vaginal form of the disease is also true to a lesser extent of the fundus. If the disease be recognised in its early stages, there is every chance of the patient being restored to health; the disease, however, is not readily recognised.

Women often have this form of disease existing without any symptoms whatever—no pain, no discharge, no inconvenience, as the disease progresses, perhaps the menstrual flow is noticed to be a little excessive, or between the periods there is a slight bleeding, but this does not attract much attention, but how ominous!

Matters thus are allowed to proceed; then the patient experiences a sense of weight and perhaps some pain in the sacral region; the menstrual flow increases in volume, and continues somewhat intermittently for some days after the regular flow has ceased. Then perhaps she consults a friend or possibly her medical attendant, who probably at first, owing to the age of patients suffering in such a manner being usually between the forties and fifties, assures her she is suffering from that *bête noir*, "change of life," and treats her accordingly. Matters, however, steadily go from bad to worse, then an examination is deemed advisable. Probably very little is to be felt; the os is healthy, the uterus perhaps somewhat large and heavy, in other respects there is little to denote any existing disease. By the speculum a muco-gelatinous discharge will be seen exuding from the os, possibly blood-stained, otherwise denoting nothing more than some endometritis. If a sound is passed, however, it will usually cause some bleeding, the uterine cavity

will be found in many cases elongated and enlarged.

Under such circumstances suspicion should always be aroused, and curetting the uterine cavity advised, with a view of having the *débris* examined by a competent pathologist; but often this report is disappointing and fallacious.

Even here we are beset by difficulties, for, as Sir Halliday Croom, in a most interesting paper has pointed out, we apparently cannot always be guided by the pathologist's report. In this paper he quotes two among several cases in which he had curetted the uterus and as a matter of routine sent the *débris* to the microscopist for examination, and received the reply in one case, "Malignant." A second examination from the same authority gave the same report. Sir Halliday Croom was still sceptical, and did not feel justified in operating. The patient went to London and her uterus was again scraped, and the *débris* microscopically examined, the report being "there is nothing at all."

Another case in which a small scraping was pronounced to be malignant by the pathologist, the uterus was removed, but no trace of cancer whatever discovered, but only a fungating polypus.

I quite agree with Sir Halliday Croom that when submitting scrapings, &c., for microscopic examination we should send with them a report of the condition of the patient from whom they have been taken.

CANCER OF THE CERVICAL CANAL.

The most frequent part of the uterus to be affected is undoubtedly the cervical canal. The importance of early diagnosis here is very much more to be insisted on than when the disease attacks either the os or fundus, for here the disease commencing in the glandular tissues quickly invades the whole thickness of the cervix eating its way downwards to the os, forming a large fungating growth, and also infiltrating the cellular and areolar tissues around the cervix extending often to the bladder. These cases are by far the most unfavourable for any form of treatment. They usually are not recognised until the disease becomes firmly established. From the fact that the disease has commenced in the cervical canal patients have often been examined in fairly good time, and the os being found smooth and apparently healthy the more deeply seated disease has been overlooked, and although by digital examination the cervix feels harder than normal, there is little to indicate the nature of the existing disease. If a sound is passed usually bleeding will be caused, and this should excite suspicion; and if any doubt exist a small curette can be introduced and a portion of the mucosa and deeper tissue removed for pathological examination, when the true nature of the disorder will be recognised.

The importance of early diagnosis in this form of the disease cannot be over-estimated as the parametrium rapidly becomes invaded and the uterus fixed quite early; later, the ureters are implicated and the sacral glands affected. The peritoneum, bladder, and rectum are later invaded through the lymph channels. When the ureters become involved and constricted, the kidneys speedily become disorganised and the patient dies of uræmic poisoning.

In many cases of cancer of the cervix uteri, on removal of the organ and careful examination of the muscular tissues, isolated patches of carcinomatous disease will be discovered, which Professor Jacob ascribes to the extension of the disease through the blood vessels anastomosing between the cervix and the body of the uterus. This point is very important to remember in connection with the treatment to be recommended, as it is clear from such a condition existing nothing short of total removal of the uterus could be of any avail in freeing the patient from the disease.

AFFECTION OF THE GLANDS.

A question of very great importance arises as to the affection of the glands in cancer of the uterus. My own experience, based in the first instance by

examination of a large number of cases in the *post-mortem* room, led me to the conclusion that glandular infection did not exist nearly so frequently as was imagined; even in patients who had died from advanced cancer of the uterus I frequently found but little infiltration of the glands of the pelvis or iliac glands, and in some cases which had died after operation the glands were not apparently affected at all. My experience corresponds to that of other observers who have paid attention to this subject, and as this must necessarily influence our advice as regards operation it is most important. Krömer, Giessen (*Archives f. Gyn.*, Bd. lxxiii., S. 57), who has investigated the course of the lymphatics in the cadaver in thirty cases, nine of which were carcinomatous, points out that experimental injection gave results agreeing with those of Brihus and others. His results necessarily point to the necessity of strictly separating the malignant tumours of the uterus according to their seat and histological structure. From his observations there can be no doubt that while the lymphatics become somewhat early invaded when adeno-carcinoma exists in the cervix extending into the parametria, yet in those cases when the disease is limited to the fundus the lymphatic system is rarely, or, at any rate, very tardily infected. The same applies to early carcinoma of the os of the squamous-celled variety.

Schauta, Vienna (*Monats. f. Geb. u. Gyn.*, Bd. xix., S. 475), records much laborious anatomical research into the condition of the glands in uterine cancer. These results would indicate that the complete radical removal of carcinoma of the uterus, with all carcinomatous glands in relation with it, is possible only in the most exceptional cases in which the glands are not affected at all.

Doederlein removed enlarged glands from the pelvis in 65 instances, and these were cancerous in 22.8 per cent. of the cases; but in only 9 per cent. of cancers of the corpus uteri, and in those the disease had broken through the uterine wall. Pankow quotes that he removed the glands in 40 per cent. of all cases operated on by him, and only 50 per cent. of these proved to be cancerous.

Mackenrodt, Berlin (*Monats. f. Geb. u. Gyn.*, Bd. xix., Hft. 4), finds that in 95 per cent. of all cases in which the glands are infected only those of the first line are so. The rare infections of the glands of the second line are far less dangerous in regard to local recurrence than the glands of the first line close to the cicatrix.

OPERATION.

In discussing the question of treatment of carcinoma of the uterus by operation it must be borne in mind what I have already said respecting the extent and position of the disease, as by studying this one is more able to decide as to the wisdom of recommending an operation or not. Now, as I have shown, the iliac and sacral and lumbar glands are not found to be affected in nearly so many cases as one would suppose—indeed, I am convinced that the glands escape infection in the majority of these cases in which the disease is limited either to the os uteri or the body of the uterus, whereas in those in which the disease commences in the cervical canal and extends into the areolar tissue between the vault of the vagina and peritoneal cavity, the lymphatics become somewhat early infected, and metastasis will be found to exist in the gland. In these latter cases the chances of a radical cure of the disease is very small, yet if seen early enough doubtless much relief can be obtained by free excision of the uterus and the areolar tissue and parametrium, the patient's life being prolonged, and her latter days made more bearable.

The question which must exercise our minds most is to decide when we shall recommend operation; in what cases can we hold out a fair hope to the patient and her friends that benefit and possible cure may accrue from operation. Here, I think, English gynaecologists are much more conservative than our *compatriotes* on the Continent or America. Kroenig, Jena, in advanced cancer, which is immovable even under

narcosis, and in which it may be expected that the bladder and ureters are involved, operates by making a transverse incision and keeps the operative field extraperitoneal by Mackenrodt's method; in spite of the drawbacks of the increased danger of infection owing to the cavity left and the extensive wound in the connective tissue, and of increased anxiety in regard to the functions of the bladder. In six cases he records the extension of the disease rendered partial resection of the bladder and ureter necessary, but the danger from shock and escape of urine after resection of the bladder and ureters, he says, is less than by other methods. Such heroic surgery as this, I scarcely think, will commend itself to gynaecologists in this country. Surely the last state of that woman, even if the operation were successful so far as the removal of the disease is concerned would be worse than the first. I am convinced that in no case where the uterus is fixed and the ureters and bladder implicated can we expect to perform any operation which will benefit the unfortunate patient in any way. But there are cases on the border line in which we may hope to be able to get beyond the disease. I refer to those in which the os was primarily affected and the disease has extended along the roof of the vagina extending just into the areolar tissue beneath. In such a case the body of the uterus will be found to be quite mobile, while by deep pressure bimanually it will be felt that there is a narrow, somewhat hard band between the hands in the roof of the vagina, in either one or both fornices, which fixes the cervical portion of the uterus. In such a case I think we are justified in advising an operation.

In the discussion which followed upon Dr. Wertheim's paper ("Treatment of Cancer of the Uterus," *Brit. Med. Journ.*, No. 2334, pp. 689, Sept. 23rd, 1905) on the diagnosis and treatment of cancer of the uterus, read at the meeting of the British Medical Association at Lincoln, one could not but be struck by the diversity of opinion as to the best method of operation. Primarily it resolved itself into the abdominal and vaginal route, although one or two speakers recorded good results, which they had obtained by high amputation of the cervix, with the actual cautery in cases of cancer of the os.

Dr. Wertheim's paper was a very valuable addition to our knowledge, and his results are truly surprising. Since 1898, he has performed the operation as described by him in 270 cases, with a mortality of 15 to 18 per cent., but out of the last thirty cases he has lost only two.

One has only to study the description of the operation to appreciate its magnitude. The importance of the operation is all the more significant as Dr. Wertheim does not suggest any change in the present mode of dealing with cancer of the body of the uterus or of early cancer of the cervix. His paper deals with cases in which the disease has extended beyond the cervix into the surrounding cellular tissues. These are cases in which English gynaecologists have hitherto agreed that it was quite inadvisable to interfere with, by means of any operation, contenting themselves with palliative treatment. So that the results of Dr. Wertheim's operations are all the more surprising, as he tells us that from 60 to 70 per cent. of his cases have remained free from recurrence after four or five years.

Now just let us for a moment, without describing the operation to you, as most of you are already familiar with the technique of it, consider some of its special features. Dr. Wertheim tells us his early operations lasted from two to two hours and a half, with more practice he has reduced this to half that time, and anyone who has performed this operation, when the cellular tissue has been invaded by the disease, in which the ureters have been surrounded, and when the bladder has been implicated, can readily understand the operation occupying the time named. Dr. Wertheim's object as laid down in his paper is by no means undertaken with the exclusive, nor even the principal object of removing the lymphatic glands; on the contrary, from the beginning he attaches the

chief importance to the thorough removal of the cellular tissue network round the uterus. He says, in his opinion, the treatment of the ureters and the possibility offered in the way of removing the parametrium, together with the uterus, is the principal object, and that the resolve to extirpate the lymph glands was an addition.

He finds that the proportion of cases suitable for his operation has risen from 15 to 30 per cent., then to 50 per cent., and will probably rise higher in the future.

An important histological result of his operation has been in the examination of the glands. Many thousands of these have been removed by him and carefully examined histologically; in 28 per cent. of the cases the regional lymphatic glands were affected with cancer. The cancerous glands were always enlarged, very considerably so. In the elongated spindle-like glands which so to speak only represent a thickening of the lymphatic ducts, carcinoma was never found.

In a further 30 per cent. of the cases the glands were more or less enlarged, but no carcinoma was found within, only hyperplasia and infiltration. The experience of Dr. Wertheim is fully in accord with that of Schauta, Kröenen, and my own as already mentioned on this point.

Notwithstanding the brilliant results of Wertheim's operations, I think it will be some time before British gynaecologists will feel disposed to adopt it in cases in which the uterus is fixed, the parametrium infiltrated, and the ureters and bladder perhaps involved, yet these are cases in which Wertheim operates with a light heart, and occasionally in cases of necessity carries out a resection of the ureter and bladder.

I have performed the operation as described by Wertheim on three occasions. In one case I had removed the os and cervix with Paquelin's cautery, and the following week performed the abdominal operation.

From 1890-1897, Professor Jacob practised systematic vaginal hysterectomy in 81 cases with 1 death; 10 cases were lost sight of; of the 70 cases left—of these there was recurrence in 49 during the first year, 9 during the second, 11 during the third, and only 1 was alive after the fourth year.

Professor Jacob subsequently adopted the abdominal operation with slightly better results; of 95 operations, he had 6 deaths, 6 have been lost sight of, 48 had recurrence within a year, 26 within two years, 4 within three years, 2 within four years, 2 within five years, and 1 within six years. Of the 87 cases only 2 were alive when he read his paper.

How can we account for this enormous difference in the mortality between Germany and Belgium? Does cancer assume a more malignant type in Belgium? It can scarcely be from inexperience, as Professor Jacob is well known as a bold and expert operator. It is true, as Wertheim has pointed out, he did not expose the ureters, but can this account for the enormous difference? I can scarcely think so.

In this country, gynaecologists have not yet adopted the abdominal operation to such an extent as one would have thought after the results reported by German and American gynaecologists. Yet I find numbers who were quite wedded to the vaginal operation are beginning to veer round and practise the abdominal.

Drs. Lewers, Purcell, and I have all operated on a large number of cases by the vaginal route, with, I consider, good results. Dr. Lewers published in 1902 the after results of forty consecutive cases of vaginal hysterectomy for cancer of the uterus; of these 40 cases, 14 were alive and free from recurrence at periods varying from 2 to over 7 years.

Dr. Purcell has operated on 265 cases by the vaginal route; of these 41 died within a year from recurrence; 43 in two years; 46 in three years; 48 in five years; and 47 in six years.

I have operated on over 200 cases, with a mortality from operation of 10 deaths, but in the last 73 cases only one patient died. Of 180 of these, which were

performed over two years ago, very many have been lost sight of. Of the remainder, 17 are still alive and well at periods varying from twelve years to three years, while 20 per cent. lived and kept free from recurrence for periods varying from two to five years.

Professor Doederlein (Hegar's *Beitrag*, Bd. ix., Heft. 27) endeavours to show, by comparing the results from vaginal and abdominal hysterectomy in his klinik, that of all the cases seen 48.3 per cent. were operated on by the vagina with a mortality of 16.4 per cent.; and permanent cure in 40.6 per cent.

In comparing the relative merits of the abdominal operation with the vaginal there is still a great discrepancy of opinion, as Besson (*Sci. Med., Lille*, June 11th-18th, 1904) has pointed out, after going very carefully into the question, the mortality at present in cases operated upon is two or three times greater after total abdominal hysterectomy than after vaginal hysterectomy. The proportion of 38 per cent. of survivals in operated cases after two years appears encouraging. The greater proportion of survivals in cases operated on by vaginal hysterectomy indicates the corresponding superiority of this operation in cancers sufficiently localised.

It is difficult, then, to lay down any hard and fast rule as to which operation shall be adopted.

I think when the fundus or body is attacked it has been pretty well established that no glandular infection takes place unless the disease ulcerates through the wall of the uterus; therefore, in such cases, vaginal hysterectomy is the better operation, for the reason that shock to the system is not nearly so severe and patients make a much readier convalescence.

Vaginal hysterectomy is also, in my opinion, the better operation for those cases in which the disease is limited to the os and vaginal portion of the uterus. But when the disease has extended up the cervical canal, infiltrating the cervix and possibly infecting the cellular tissue, then the abdominal route or perhaps the combined abdominal-vaginal operation would be the wiser if not the only operation which would hold out any hope of success.

Lastly, those cases in which the uterus is fixed and the ureters and bladder possibly implicated, I am convinced they are better left rigidly alone, notwithstanding Professor Wertheim's brilliant record.

THE MORISON LECTURES ON THE PATHOLOGY OF GENERAL PARALYSIS.

DELIVERED IN THE ROYAL COLLEGE OF PHYSICIANS,
EDINBURGH, ON JANUARY 24TH, 26TH, AND 29TH.

By W. FORD ROBERTSON, M.D., F.R.C.P. EDIN.

ABSTRACT OF LECTURE III.

In discussing the problem of etiology and pathogenesis of general paralysis and tabes dorsalis in the light of the investigations detailed in the two preceding lectures, Dr. Robertson wished as far as possible to avoid a controversial attitude. His purpose was simply to endeavour to show that a new and solid edifice could be constructed out of the facts elicited by his colleagues and himself. A passing critical reference to the syphilitic hypothesis was, however, inevitable. He contended that the part played by syphilis was only that of weakening the general and local defences. There were many strong reasons for believing that these diseases could not be essentially syphilitic in their causation, and moreover there was the clearest evidence that the general paralytic suffered from an active bacterial toxæmia. Having summarised the evidence in support of the view that general paralysis and tabes dorsalis are dependent upon infection by a diphtheroid bacillus, he described what appeared to him to be the essential pathogenesis of these two diseases. In general paralysis, the specific bacillus appeared to be conveyed from individual to individual by contagion. There was ample warrant

for the conclusion that it could neither multiply to any extent upon a healthy mucosa nor invade the tissues. A preliminary weakening of the local and general defences was evidently necessary. There were numerous inimical forces that could produce this condition of impaired local and general defence, but there were three that seemed of special importance in relation to general paralysis and tabes dorsalis. They were the pathogenic agent of syphilis, alcohol, and nitrogenous foods used in excess. There was evidence that a mere saprophytic infection might continue for a long time without leading to any important toxic effects. It was probably only when the state of the local and general defensive forces was such as to permit of the bacillus invading the tissues that the paralytic toxæmia became of any great intensity. Of the occurrence of such invasion there was ample evidence. The more recent observations of Dr. McRae and himself had led them to attach special importance to the bronchi as a seat of chronic infection, although there were many cases in which bacillary invasion could be shown to have taken place from the alimentary tract. It was virtually a life and death struggle between the bacilli and the polymorphonuclear leucocytes. It was a conflict in which the leucocytes after a long succession of victories were ultimately defeated, for their power of renewal was limited, whilst that of the bacilli was virtually unlimited. Under certain conditions the defensive forces were placed at a disadvantage. One of these conditions had been ascertained experimentally. It had been found that lowering of the temperature four or five degrees (C.) below the normal greatly diminished the power of the leucocytes to take up these bacilli. It was therefore reasonable to believe that lowering of the body temperature was an important cause of aggravation of the bacillary attack. Local invasion manifested itself clinically in a congestive attack. Large numbers of the bacilli reached the circulation either by way of the lymphatics or through the capillary walls. They could be seen in the blood stream in the neighbourhood of the infective foci and also in films made from the patient's blood during life. Most of the bacilli that reached the blood were quickly seized by leucocytes and digested, but many escaped from the circulation in one or other of two ways, namely, through the capillaries of the kidney into the urine and through the walls of the cerebral vessels into the adventitial lymph-channels. The further disintegration of the bacilli that took place in these lymph channels gave rise to a local toxic action. There was thus a general toxæmia due to the disintegration of the bacilli at the seat of invasion and in the blood and an added local cerebral toxic action dependent upon the disintegration of the bacilli that had passed through the endothelium of the cerebral vessels. In some instances a successful repulsion of the invasion was followed by a prolonged period in which the bacillus was kept at bay. Clinically, this corresponded to a remission. More commonly there was a continuous comparatively slight absorption of toxins from the infective focus and a succession of more or less severe invasions, which time after time were repelled. In the end, however, the defensive forces were overcome. There was then a fatal congestive attack. Coming next to the subject of the pathogenesis of tabes dorsalis, he referred to the recent observations of Orr and Rowe upon the production of tabetic lesions of cord by the absorption of toxins from peripheral septic foci. The toxins passed up the perineural sheaths without injuring the nerve fibres and affected the fibres of the posterior root as they entered the cord at the spot where they lost their neurilemma sheath. In order to account for the similar lesions that occurred in tabes it was necessary to find some peripheral toxic focus. So far as their evidence went, it pointed to this focus being in the bladder. In ten consecutive cases of tabes they had found that there were abundant living diphtheroid bacilli in the urine, and therefore the patients were

suffering from a diphtheroid cystitis. In these cases the bacilli were present in too great numbers to have come merely from the urethra, which in other cases very frequently contained some diphtheroid bacilli. If further observations confirmed the testimony of these ten cases, then they would be bound to conclude that in tabes dorsalis there was in the urinary tract an infective focus comparable to that which occurred in the respiratory or alimentary tract in general paralysis. The bacilli were invading and therefore produced toxic effects far greater than those that resulted from the simple passage of disintegrating bacilli through the urinary tract. After referring briefly to some objections that might be raised to the views advanced, he considered the question of treatment. There was evidence that the general paralytic defended himself, and often with prolonged success, by manufacturing specific bacteriolytic anti-bodies. It seemed therefore worth while to produce such anti-bodies in suitable lower animals, and to use them as therapeutic agents. They were at least going to give this method of treatment a trial. In conclusion, he said he desired to acknowledge his indebtedness to the General Board of the Laboratory of the Scottish Asylums, to the representatives of the Edinburgh, Glasgow, Dumfries, Aberdeen, and other asylums, for the facilities they had afforded his colleagues and himself for carrying out their researches.

CLINICAL RECORDS.

A CASE OF VAGINAL CYST.*

By H. MACNAUGHTON-JONES, M.D.

The patient, æt. 35, was curetted for glandular endometritis in September, 1905. During the operation a cystic tumour was found in the vaginal vault about the size of a large pigeon's egg. While dissecting out the cyst it ruptured, when some glairy fluid escaped, so that it could not be removed completely. The pathological report on the portion of cyst wall sent for examination was that it might be a retention cyst and was lined by spheroidal epithelium.

In December, 1905, the patient returned complaining of vaginal distress and pain, and on examination I found a fair-sized cyst low down on the posterior wall, inclined rather to the right side. This was about the same size as the one previously removed, and contained thin clear fluid.

There was some difficulty in dissecting out this cyst, as the wall was thin and incorporated with the subjacent tissue in the recto-vaginal septum, closely approaching the rectum. Through a small cut some of the fluid contents escaped. The accompanying drawing shows the cyst considerably reduced in size owing to shrinkage in the preservative fluid. The pathological report states the cyst is circular, one inch in diameter and is surrounded by fibro-muscular tissue. It has a convoluted waxy lining, and in the depth between the folds the microscope shows a lining of cubical epithelium.

I am not aware of any published cases in which there have been two cysts of the size I have mentioned, and obviously of different portions of the vagina. It seems to me the cyst in the vaginal vault was glandular in origin, while that in the lower portion was of a Gartnerian or Wolffian nature.

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL.

A CASE OF "SUCCESSIVE" SYPHILITIC CHANCRES ONE GENITAL AND THE OTHER EXTRA-GENITAL.

By HENRI DARDENNE, M.D. EDIN., M.R.C.P. LOND.

AMONG the out-patients on October 20th, 1905, was a man, by occupation a clerk, with a painful sore on

* Read before the British Gynecological Society, Feb. 8th, 1906.

the index finger of his right hand, and also with another one on the corona glandis. On examination they were found to be syphilitic.

The history was briefly: On September 18th the patient had connection, and three weeks later he noticed a slight red pimple on the corona. Five days later he noticed a slightly painful sore on the dorsal aspect of the first phalanx of the right index finger. This became rapidly worse, and for the last three nights he said that the pain prevented him from sleeping. The inguinal glands were enlarged, and three or four could be felt in each groin. They were hard and slightly painful. On the glands the chancre was characteristic.

The chancre on the index finger was about the size of a sixpence. It was covered with thick black crusts and looked most unhealthy and malignant. It was exquisitely painful, and distinct red lines could be seen arising from it up to the lower third of the dorsal aspect of the forearm. The olecranon gland was enlarged to the size of an average chestnut. The chancre in shape was circular. The induration was characteristic of chancres in such a situation—*i.e.*, not one that could be distinctly felt, and exactly the size of the chancre, but it was massive. The skin, subcutaneous tissue, and tendon were fixed, and formed one mass with the bone below.

Dr. Dardenne made the following remarks:—Extra-genital chancres may affect any part of the body, this depending on the mode of contagion. In children they are chiefly to be seen on the face. The lips, the cheeks and the eyelids are the parts most frequently affected. Persons affected with mucous patches and kissing these children are the source of contagion in such cases. In adults extra-genital chancres, when affecting the chin present one peculiarity, and that is, their multiplicity. Five, six and seven chancres have been seen in that region. He had had a case which showed four distinct hard chancres. The man suffered from chronic sycosis and was in the habit of being shaved by barbers.

Extra-genital chancres have long been thought to be the precursors of a syphilis more malignant in nature than that acquired in the usual way. No doubt that at times the syphilis of which they are the primary symptom is most virulent. This is a mere coincidence, and is due to the nature of the soil. Patients with early sclerotic changes in their blood vessels are more apt to suffer later on from cerebral syphilis than those with a good constitution and healthy vessels. The treatment is generally much delayed, the lesion not being recognised from the first; in many not until tertiary symptoms have made their appearance and all the patient's arteries are already affected with the syphilitic arterio-sclerosis. Coincidence consisting in the nature of the soil and late and bad treatment have been the two reasons in affecting the prognosis of extra-genital syphilis, and hence has arisen this popular belief.

The case under consideration, Dr. Dardenne pointed out, presented another interesting and most rare feature. The chancre on the index finger being "successive," *i.e.*, appearing five days after the one on the genital. It was most characteristic. According to Diday, Kopp, Fournier, the interval is usually from one to twelve days. It has been noticed up to twenty-five days after the first chancre. This, however, is open to caution. Balanoposthitis causing ulceration; herpes and secondary lymphangitis, with interrupted nodular indurations, have been mistaken for real indurated successive chancres. The "successive" chancre is also considered to be smaller, more indolent and benign than the primary, the constitution having already been immunised to a certain extent. In the present case it was the reverse, and the "successive" chancre was by far the more virulent one of the two. With regard to treatment, the genital chancre was treated with black wash and calomel ointment, and extreme cleanliness was enforced as most necessary for its cure.

Nothing, he said, was more grateful for the relief of

the exquisite pain of the finger than constant immersion in a warm boracic lotion, and this for two and three hours at a time. The inflammation and the pain soon disappeared, and the sore assumed a healthy and granulating aspect. During the night and in the intervals of the bath the finger was fixed by a light cardboard splint, and dressed with calomel ointment. The patient was also rapidly put under the effects of mercury and the salt which Dr. Dardenne generally uses is prot. iodide. In this case half a grain three times daily was increased in a few days to three grains in the twenty-four hours. Within a month the sores had completely healed. Dr. Dardenne said he could not too strongly emphasise the most excellent effect of the prolonged immersion. Chancres of the most virulent and malignant aspect which would soon become phagedenic and gangrenous improve rapidly and are soon cured by this mode of treatment. Phagedænis, which is caused chiefly by dirt and meddling treatment with irritants and caustics in a weak constitution, was thus, he considered, in the majority of cases even of the worst description avoided when such treatment was carried out thoroughly and at once.

OPERATING THEATRES.

TOTTENHAM HOSPITAL.

OPERATION FOR RECTAL CARCINOMA.—Mr. H. W. CARSON operated on a married woman, æt. 35, who had been admitted suffering from severe pain and continued diarrhoea. The patient gave a history that she had been losing strength for some months; she could give no definite statement as to the beginning of the trouble, but she complained that for the last few weeks sacral pain had been almost constant, and diarrhoea had been very troublesome. She had not sought advice until one week before admission, when she was seen by a medical man, who advised her to go into hospital. Examination of the rectum showed a growth implicating the anterior wall of the bowel at a point that could just be reached by the tip of the finger. Under an anæsthetic the growth could be freely palpated bimanually, and it was found to extend towards the left pelvic wall, and a hard tumour could be felt in the situation of each ovary. Abdominal examination was negative. In the hope of being able to remove the growth by the abdominal or the abdomino-perineal route, the patient was put in the Trendelenburg position, and the abdomen opened in the middle line. The sigmoid loop was found adherent to the fundus of the uterus; when this was freed a large growth was found in the anterior wall of the upper part of the rectum extending outwards into the broad ligament on the left side. Both ovaries were the seat of stony hard growth; a cancerous nodule was found in the sigmoid at the point where it had been adherent to the fundus of the uterus; a small nodule was present in the omentum, and secondary deposits were found in the lumbar glands. Radical operation being obviously impossible, the wound was closed and inguinal colotomy done. Mr. Carson remarked that the case was instructive in many ways. The insidious onset was very characteristic, it being quite unusual for malignant disease of the rectum to give definite signs in its early stages; it resulted from this that nearly 50 per cent. of cases when first seen were too advanced for successful radical operation; in a few cases hæmorrhage was the first sign, and these cases generally sought advice early. Mr. Carson referred to the case of a man upon whom he had operated two and a half years ago, who had suffered, whilst apparently in excellent health, from a severe rectal hæmorrhage.

Examination proved that he had a small malignant ulceration; this was readily removed, with the result that the patient is now in excellent health. Another point of interest in the present case, Mr. Carson remarked, was the patient's age; 35 was decidedly young for malignant disease of the rectum. It was doubtless due to this cause that the growth had been so rapid. A point of great importance, he thought, was that in this case, as in so many cases of malignant disease of the rectum, the principal sign was diarrhoea, and Mr. Carson urged the imperative necessity of a rectal examination in all cases of prolonged diarrhoea. Strauss's proctoscope, he said, was a valuable instrument in the diagnosis of growths situated high up, as it admitted of a thorough examination of the lower ten inches of the bowel; an anæsthetic was not necessary, and the passage of the instrument was free from danger if ordinary care were taken. With regard to the colotomy, he advised that the method of choice should be one which admitted of great rapidity, especially if immediate opening was unnecessary, as patients requiring colotomy were usually in a condition which rendered any prolonged operation inadvisable. He recommended that as small an opening in the peritoneum as possible should be made, the colon well pulled down, and a loop fixed in position by means of a glass rod passed through the mesentery; a single suture at the top and bottom corners passed through the longitudinal band and the abdominal wall, being all that was required to complete the operation.

GREAT NORTHERN HOSPITAL.

THYROIDECTOMY—MR. PEYTON BEALE operated on a man, æt. 25, who had been transferred from Dr. Morison for extensive enlargement of the isthmus and both lateral lobes of the thyroid. The patient's history was as follows: He was deaf and dumb and there was evidence that when a small boy he had suffered from one or more "fits," the thyroid enlargement was of some months duration and on admission the thyroid was exerting so much pressure on the trachea that the patient even when at rest had great difficulty in breathing. The man was anæmic and had slight albuminuria. Operation was, however, absolutely essential although Mr. Beale said he would not have performed it had it not been necessary to save life. It might be mentioned he said, that the isthmus was so large and extended downwards to such an extent that tracheotomy was impossible. An incision was made vertically over the right lobe, this last was freed with considerable difficulty and brought out of the wound. It was then found that it, together with the isthmus, was very firmly adherent to the larynx and trachea. The right lobe was removed, numerous ligatures being applied between it and the isthmus. It was now seen that the patient's respiration was not in any way improved; it was not possible to take away the isthmus, as it was so adherent that it could neither be dissected or peeled off without the certainty of wounding both larynx and trachea. It was therefore decided to remove the very large left lobe, and this was found to be more difficult than the right, owing to the adhesions between it and the important structures to the left of the trachea, thus the isthmus alone was left (a mass about the size of a tangerine orange) and the lower part of this was separated from the trachea so that tracheotomy might be done if it should be found necessary. The wounds were dressed in the ordinary way. The patient did perfectly well for six days: on the sixth day he developed some difficulty in breathing and very marked symptoms of tetany, spasmodic contraction of all or

nearly all the voluntary muscles being readily evoked by touching the skin over them, this was most marked in the face. It was then observed that he was breathing with his diaphragm only, his ribs did not move at all, and his sternum was drawn inwards at each inspiration; this was clearly due to the contraction of the sternal fibres of the diaphragm. The patient was seen by Dr. Beevor and Dr. Morison, who advised full doses of thyroid extract, it being clear that the man was suffering from loss of thyroid tissue. Under this treatment he gradually improved and in a fortnight was quite well. Mr. Beale said that this was the first case in which he had removed both lobes of the thyroid and he would not have done it here had he seen any other way of relieving the pressure on the trachea. The interval of six days seemed rather a long one; he would have supposed that symptoms of tetany would have come on much sooner; tetany had been observed after removal of too much of the thyroid in previous cases, but he had not himself come across any. The paralysis of the muscles which elevated the ribs in inspiration was, he supposed, an example of paralysis or paresis of a group of muscles such as had also been observed in previous cases, but he did not know that paralysis of this particular group had been described. Had there been any paralysis of the diaphragm he would not have been surprised, the adhesions in the neighbourhood of the phrenic nerves, between them and the lateral lobes of the thyroid were so dense that injury to the nerves was to be expected.

Collier and Barber.

At Tredegar on Tuesday (before his Honour Judge Owen) Job Lugg, collier, Beaufort, claimed £30 damage from Walter Bishop, hairdresser, Brynmawr, in respect of barber's rash, alleged to have been contracted by shaving at defendant's shop. Plaintiff said he was shaved at defendant's shop on October 7, and defendant's assistant, while performing the operation, was talking about football, and cut him on the chin; then wiped his face with a towel hanging up, and on which there were spots of blood. A few days afterwards eruptions broke out on his face, and on November 10 he gave up working and consulted a doctor. About the end of October defendant was informed and told that the eruptions were caused by the negligence of his assistant, and he replied that he warned him several times. Defendant said he would report the matter to the Hairdressers' Association. In cross-examination plaintiff denied that there were eruptions on his face previous to this, and he denied stating that he had been shaved at several shops. He had seen a report of a case in London on January 2 in which damage had been awarded, and he went to see the defendant on January 8. Dr. Dwyer, Beaufort, stated that he examined plaintiff and found him suffering from barber's rash. In reply to Mr. Parsons, witness said that barber's rash was identical with ringworm, and could be contracted from dirty cats and dogs. His Honour, in giving judgment for the defendant, said there were circumstances of a serious nature in the case which were not for him to deal with, but which might be dealt with hereafter.

The Danger of Soothing Syrups.

An inquest was held at Todmorden on the 12th inst. on the body of Leonard Wild, aged four weeks, son of Francis Wild, cotton piecer, Millwood. It was stated that the child had been in poor health since birth. A dose of soothing syrup was given to it on Saturday, and the child slept for so long a time that the parents became alarmed, and called in a doctor. Death took place next day. The soothing syrup had been found to contain opium. The jury returned a verdict of "death from intestinal atrophy." The Coroner spoke strongly against the practice of giving these soothing syrups to children.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

SPECIAL MEETING HELD FEBRUARY 8TH, 1905.
Mr. F. B. JESSETT, President, in the Chair.

THE PRESIDENT thought this was an important meeting, and required some explanation as to why it was called. Those who were at their last annual meeting when the election of the Council took place would remember that there had been a good deal of discussion as to the validity of the notice of that meeting. The President had then ruled that the form was in order, but after the Officers and Council were elected they found that only twenty-three Fellows were elected on the Council. The Articles of Association stated that there must be twenty-four members. He then called a council meeting and suggested that twenty-four Fellows should be elected, but it was pointed out to him that that would be against the Articles of Association. They therefore adjourned that meeting. Since then he had been advised that the only way to get out of the difficulty was to have paragraph 8 (i.) of the Articles of Association altered by adding the following resolution:—"That in the event of any vacancy occurring amongst the officers of the Society or in the Council, by death, resignation, or in any other manner, the Council shall have power to fill such vacancy from amongst the Fellows of the Society. And any Fellow so appointed by the Council shall hold office until the next annual meeting." Eighteen Fellows of the Society had asked him to call a meeting for that purpose so as to put that in order, because it was clear that if it were not put in order whatever the Council did during the remainder of the year would be out of order. That meeting was called for that purpose and he could not think that there was a single Fellow in the Society who would question the wisdom of their action. In the present Articles of Association there was no provision made for filling up any vacancy during the year were such to occur.

Dr. BENNETT moved, and Dr. ROUTH seconded the proposed resolution, and the PRESIDENT then put it to the meeting, when it was carried *nem. con.*

Dr. SIMON proposed—

"That in view of the proposed amalgamation of London Societies recently brought before this Society and approved of, 'The examination of nurses be discontinued.'"

Dr. TRAVERS seconded.

Dr. HEYWOOD SMITH said in case that amalgamation did not take place the question of the examination of nurses might be continued. Would it not be better to leave the matter as it was until the question of amalgamation came up?

Dr. FENWICK, as one of those who were interested in carrying out the scheme with regard to the examination of nurses, said he thought it was only fair to mention that for the first two years it was a great success, until the Council prevented the nurses from going in for examination at all. It was a matter of perfect indifference to the Board of Examiners whether the scheme went on or not.

The resolution was carried with only one dissentient.

Dr. PURCELL then proposed, Dr. BENNETT seconded, and Dr. FENWICK supported a resolution that Dr. Macnaughton-Jones be made a Member of the Council. The resolution was unanimously adopted.

The ordinary general meeting then commenced. After the minutes had been read and confirmed,

Dr. FENWICK read notes on a specimen of
UTERINE FIBROID WITH PREGNANCY.

The patient from whom this specimen was taken was sent to me by Dr. Hosford, of Holloway. She was æt. 36, and had only been married 4½ months. Her periods commenced at 12, and had always been

quite regular, the loss being normal in quantity and lasting four days. For the last year or two she had complained of increasing constipation and frequency of pain with micturition. The last period finished on September 6th, and was normal in every respect. Ever since she had complained of increasing pain in the left side and swelling of the abdomen. When I saw her there were two distinct nodular masses above the pubes, the pelvis being filled by a densely hard nodular growth which could not be moved. The cervix was drawn up behind the pubes and felt soft, but could only just be reached by the finger. The swelling on the left side was softer than that on the right of the abdomen. The vagina was a little discoloured and there was a little secretion in the breasts. The diagnosis was 4 months pregnancy with an impacted fibroid. It would have been difficult to induce labour, and the increasing pain and rising pulse showed that pregnancy could not continue to full time. If labour had been induced the fibroid, filling the pelvis, might have prevented the extraction of the fœtus, and the fibroid to the right side might have prevented complete clearance and contraction of the uterus. On January 16th I therefore performed supra-vaginal hysterectomy, and with some difficulty lifted the lower mass from the pelvis into which it was firmly moulded, and it will be noticed the pelvic out-growth which arises from the cervix has so twisted and compressed the cervical orifice that it is doubtful if the canal could have been opened sufficiently to allow the fœtus to pass. The patient recovered quickly.

Dr. ROUTH asked how long the patient had been pregnant when the operation took place, and said he was inclined to object to that hysterectomy. He had met similar cases himself where a tumour grew to a considerable size and he had generally found one of two things occur. As the child grew it was pushed generally on one side, or especially above, and then by bringing on labour about the eighth month or so they got a live child. Unless the tumour were very large he thought that was the proper thing to do. In these days of diminishing population in their great Kingdom, he did not think they had a right to destroy children when it could possibly be avoided. He remembered one case of a very large tumour, where he allowed the woman to go on to about the full period. After using the forceps, he succeeded in getting the child out alive, and it was living now as far as he knew. He knew of another case in which similar circumstances occurred, but in a different manner. When the patient was first examined there was a tumour, and it seemed to him that the tumour would prevent the child being born. As the case progressed the tumour quietly made its way up to the top of the uterus, and the woman was delivered safely. He considered that people were too fond of hysterectomy. He therefore thought it was important before removing the child or the tumour, to wait a little while until nearer the full period, and then if necessary open the belly from the front and save the child.

Dr. PURCELL said it seemed that the uterine wall contained three other fibroids in addition to the specimen shown, so that if the woman had been allowed to go on to full term, or a Cæsarean section had been done, the child might have been saved, but the uterus would have had to be eventually removed.

The PRESIDENT asked if the patient had any urgent symptoms?

Dr. FENWICK replied that she had great pain and a rapidly rising pulse, it was 120 when the operation took place. It was very difficult for him to say anything after the reasoned judgment which they had had from one of the veterans of the profession. But he was forced to retain his own opinion that with a fixed

calcified mass like that in the pelvis, he could not understand how any child of any size could be brought out. The canal would barely admit his finger. He did not think the patient would have lived another five months had she not been operated upon.

Dr. MACNAUGHTON-JONES showed a specimen of vaginal cyst, which will be found fully reported on page 159 of the present issue.

Dr. ROUTH said the cases were interesting particularly as their anatomical and physiological characters were well explained. He wished to allude to some kinds of cysts in the vagina which were puzzling. A patient, of his æt. 18, evidently had a cyst in the side of the vagina extending from about an inch above the external opening right up the vagina. It was undoubtedly a cyst because when the one finger was placed in the rectum and the other in the vagina fluctuation could be felt. The cyst was about the size, he supposed, of a small sausage. He did not at the time think it was a cyst. He removed a quantity of pus. The case went on and the discharge continued for some time, but gradually ceased. One day when examining her with a sound he found that it led into a second uterus. As a matter of fact, the contents of this second uterus had been poured into the so-called cyst, which turned out to be a second vagina, which he opened up and no further discharge took place. There was another case, not his own, but which he had the opportunity of examining. It was a case of Dr. Greenhalgh's at St. Bartholomew's. On examining the patient the vagina and uterus were found to be natural, but a little closer examination revealed something like a cavity in the side of the vagina at the opposite side. This was found to be another vagina extending upwards, and led to another uterus. When the sound was passed in it went right up into a uterus. Those two cases proved that what they sometimes took to be a sort of abscess or cyst in the vagina was in reality another vagina, or part of it.

Dr. SAVAGE said he happened to have an opportunity of seeing a case of Professor Taylor's about a fortnight ago, and it was very similar to the case which Dr. Routh mentioned in which there was a kind of sausage-shaped swelling on the right side of the vagina and extending upwards and backwards. When opened it led into a cavity which seemed to occupy the right broad ligament. The lining of that cyst was thick and the contents were composed of clot and fluid, and seemed like serum. Professor Taylor thought it was a case of second uterus and second vagina. He happened recently to see in the *British Gynaecological Journal* of some two or three years ago an account of vaginal cysts, and it was mentioned that hæmatoma of the vagina following pregnancy might occur and simulate those cysts.

Dr. MACNAUGHTON-JONES said in reply that one source of vaginal cysts he had mentioned was closure of the vaginal folds, which just met what Dr. Routh had said. It was mainly on the character of the epithelium that the diagnosis depended.

Dr. MANSELL MOULLIN showed three specimens of uterine myomata. The first case was a portion of a large multi-nodular tumour removed from an old lady of 53. This was a class of tumour which was supposed not to occur after the menopause. But the tumour became degenerated, and therefore caused symptoms. The specimen was an example of calcareous degeneration. Part of the omentum had become adherent to the calcareous portion and the bowel itself was adherent. He had succeeded in removing the tumour, and the old lady was delighted to be rid of what had caused her so much discomfort for about two years. The second specimen was a calcareous tumour. It was quite hard and an opening had been made in one soft portion of the wall. It proved to be a calcareous shell, the contents were mucoid, and it was found entirely detached from a large tumour which was

removed at the same time. It was intimately adherent to the bowel and the omentum, as in the previous case. The third specimen was an example of soft myoma of the submucous variety. It had been entirely contained in the uterus, but now the greater portion of the tumour was exposed. The tumour suggested that it could have been very easily enucleated, but the patient was an unmarried elderly lady, and the hymen only admitted just the tip of the finger. The tumour extended up to the umbilicus, and he did not think any operator would have suggested removing it otherwise than from above.

The PRESIDENT asked what was the result of the operation and Mr. Mansell Moullin replied that it was very satisfactory.

Dr. MACNAUGHTON-JONES remarked that the first specimen was very interesting from the fact of the multiple myomata which were contained in the mass. The practical point was that these multiple myomata were found more frequently after the menopause, and often gave rise not only to discomfort, but also to most dangerous and fatal hæmorrhage. Dr. Mansell Moullin's specimen of calcareous degeneration was really a beautiful and very rare one. As a rule they did not get an isolated calcareous mass such as occurred in that case. There was another point to be noted in connection with the first specimen, namely that the hyaline degeneration which was got in myoma frequently preceded calcareous degeneration. Calcareous degeneration was not frequently found in young people. It was found in women who were rather advanced in life more frequently than in young women. The practical points connected with the first two cases were these: That they both afforded irrevocable proof of the value of early interference with myomata. They showed that if an operation were postponed until there was a whole mass of small myomata growing and increasing, then, if these did not succeed in killing the woman before the operation, they led to pain and discomfort and possibly to secondary degeneration independent of the multiplicity of the myomata. Therefore, the two specimens were not only from the operative point of view valuable, but they additionally proved the necessity for early operation in myoma.

Dr. SWANTON proposed that the third specimen be referred to the Pathological Committee for report.

Dr. MACNAUGHTON-JONES seconded the proposal, which was unanimously agreed to, that the specimen be sent to the Pathological Committee.

The PRESIDENT then delivered his address, which will be found on page 195.

Dr. MACNAUGHTON-JONES said in his opinion they should deal with cancer of the uterus just as they dealt with cancer in any other part of the body.

Dr. ROUTH, in seconding the vote of thanks, remarked that Mr. Jessett had done good work in harmonising many difficult points in connection with cancer. The paper which they had just listened to was one which every man in that Society who had a love of investigating scientific and difficult points in their profession would read very carefully. He said that while on the one hand it was perfectly true that cases of cancer were very difficult to cure, he did not agree that some cases were not cured. He believed a cure depended in some cases on the nature of the cancer. He had known old women operated upon for what was considered definitely to be cancer of the uterus, and yet they had lived to be as old as himself. Therefore he did not believe the disease was incurable.

Dr. MACNAUGHTON-JONES put the vote of thanks to the meeting, and it was carried by acclamation.

The PRESIDENT suitably responded, and afterwards announced that the next meeting of the Society would be held on March 8th. Previous to that meeting, at half-past seven, a special meeting would take place in order to confirm the resolutions they had passed at the special meeting held that evening.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, FEBRUARY 2ND, 1906.
The President, Dr. R. D. PUREFOY, in the Chair.

SIR A. MACAN exhibited a specimen of degenerated uterine fibroid. He said that after opening the abdomen of the patient he found the tumour pedunculated, and with adhesions. On section the tumour gave evidence of being an ordinary fibroma. Pain had previously been complained of. This form of red degenerative change is said usually to begin in the centre of these tumours. They are liable to be coloured, and to slough.

Dr. ALFRED SMITH exhibited a specimen of a myomatous uterus undergoing sarcomatous degeneration. The patient was about forty-five years old, married, but had no family. Her menses had ceased. Operating he found a mass of brown matter, which he took to be a polypus. He removed the entire uterus. Professor McWeeney's report on the specimen showed, apparently, a polypoid formation projecting from the mucous membrane, of undoubted sarcomatous structure. The sarcoma tissue itself was undergoing mucoid degeneration in some places, otherwise the uterus was in an advanced stage of fibro-myomatous overgrowth. Slides demonstrating the sarcomatous changes were also shown under the microscope.

Dr. HASTINGS TWEEDY considered that Dr. Smith's case showed the necessity for the early removal of all myomata.

Dr. JELLETT suggested that in Sir A. Macan's case the red degeneration might have been the result of bacillary infection.

Dr. PUREFOY instanced a case in which he removed a tumour from an unmarried woman, which underwent a dark, mahogany-brown discolouration, almost identical with that seen in Sir A. Macan's specimen, and in which the change was due to telangiectasis.

Dr. JELLETT showed two carcinomatous ovaries and a uterus removed from a patient, aged forty-seven. The tumours were so fixed in the pelvis that at first sight their removal appeared impossible, but, on making a transverse incision from the centre of the usual mesial incision outwards towards the left anterior superior spine, it became possible to pass the fingers below the left ovary, and so to work across the pelvis to the right. The broad ligaments were so infiltrated that it was impossible to tie them, and the uterus was in consequence removed, hæmorrhage being controlled by two clamps passed upwards from the vagina. There was a large collection of very foul pus in Douglas' pouch, and from this an infection of the abdominal wound resulted. The patient, whose pulse at the end of the operation was 160, made an uneventful recovery, save for the wound infection. At the present time, six months after the operation, she states that her health has been good, and that she has gained in weight. On examination, however, it is probable that a return is taking place in the tissues round the rectum.

Dr. JELLETT also showed a double pyosalpinx, and the remains of an extra-uterine foetus removed from a patient who had been pregnant eighteen months before the operation, and who had believed that she had miscarried. No ovum, however, was seen at the time, and the condition, of the removed foetus made it probable that it had been retained since the supposed miscarriage. The foetus was aged about 4½ months.

Dr. KIDD said the first case reminded him of one of sarcoma of the ovaries, in which the hæmorrhage was so profuse after removing one ovary that he decided to let the other alone.

The PRESIDENT doubted the value of operation in such cases.

Dr. J. SPENCER SHEILL then read a paper entitled "Sequel to an Attack of Eclampsia." The patient,

a young primipara, had had her left kidney removed three years previously for tuberculosis. She contracted eclampsia in March, 1905, when about 5½ months pregnant. She had seven seizures, which caused the death of the foetus. Her uterus was emptied by induction of labour, and her recovery was rapid and complete. She again conceived; and on examination early in July, 1905, was found to have been two and a half months pregnant. She was cautioned about her condition, and placed on milk diet. A little later, in spite of diet and care, she developed albuminuria, which, however, was successfully combated by appropriate treatment. Again, in December last, albumin made its appearance in the urine, this time permanently. (Edema now began to complicate this case. Although the most vigorous measures were adopted, on the 8th of last month (Jan., 1906), when she was within about a month of term, owing to the onset of symptoms which indicated the near approach of eclampsia, induction of labour was performed, and she was delivered in eighteen hours of a living child. A few hours later she had a typical eclamptic seizure, and was successfully treated. The points of particular interest are:—(a) Are there no methods by which we can with certainty abort threatened eclampsia? (b) Would it not be for the good of everyone concerned that this woman should be rendered sterile by the operation of tube tying?

Dr. PUREFOY said he believed that when our efforts to relieve the patient's condition were only partially successful, we should take measures to empty the uterus, though eclampsia may come on before we have succeeded. He thought that in the second pregnancy of this patient he would have waited considerably longer before inducing labour.

Dr. HORNE preferred to have the ovaries removed, and mentioned two similar cases of his own experience. When a patient had eclampsia once, the question was, Was she not likely to have recurrent eclampsia? The second pregnancy of this patient should have been prevented for this reason. He believed the kidneys were the primary cause of the disease.

Dr. SHEILL said that a dead foetus was a foreign body at best; and, therefore, to empty the uterus was the most natural thing to do. Noting eclampsia was imminent in the second pregnancy of this patient, he thought it was safer to induce labour. Two lives in this case were in danger; but that of the mother was paramount. Both were saved. He would like to hear their opinion.—Should sterility be effected in a patient who is liable to attacks of eclampsia?

Dr. PUREFOY said he would not render her sterile.

The following *Card Specimens* were shown:—

Dr. R. A. FLYNN—(a) Ovarian tumour with twisted pedicle and hæmorrhage into cyst; (b) parovarian cyst.

The meeting then terminated.

ULSTER MEDICAL SOCIETY.

MEETING in the Medical Institute, Belfast, on Thursday afternoon, February 15th, the President, Dr. Wm. CALWELL, in the chair.

This was a Clinical meeting, and a large number of patients were present, including many rare and interesting cases.

Dr. CALWELL showed (1) a case of Onychiauxis, a peculiar talon-like development of all the nails with a hyperkeratosis of the palms and soles. (2) A case of Bilharziosis with urine. The bladder was affected in this patient, a young lad from South Africa. He showed slight scars on the feet, and had been accustomed to run about barefooted, thus supporting the theory that the parasite enters through the skin. (3) A case of Actinomyces in the neck, now under treatment by X-rays for three weeks with steady improvement.

Professor LINDSAY showed (1) a case of thoracic aneurism. (2) A case of muscular atrophy, well-marked and progressive, in a girl æt. 19, but limited

to the right hand and fore arm. It was of three years' duration. (3) A case of tubercular Peritonitis, which had been severe, and now, after seven weeks treatment by mercurial dressings to the abdomen, and general tonics, was convalescent. Tuberculin was not given.

Dr. H. L. MCKISACK showed a pathological specimen of an aneurism of the basilar artery.

Dr. JOHN McCAW showed several cases of diseases of children, including (1) a case of Hydrocephalus in a child *æt.* 4 months, the point of interest being that the child was in apparently perfect health a fortnight ago, when it was seen by a medical man attending the family and even now seemed healthy and well nourished, with no symptom beyond the enlargement of the head from its normal circumference at that age—14 in. to 21 inches. (2) A case of Hypertrophic Stenosis of the Pylorus. The child, *æt.* 3 months, was admitted to hospital on December 1st, emaciated, with obstinate constipation, vomiting, dilatation of the stomach, and only weighing 6 lbs. The pylorus could not be felt. It was given frequent very small meals of milk and lime water, and enemata, and now weighed 12 lbs.

Dr. H. M. KILLEN showed a case in which a wound of the sclero-corneal region was treated by the flap method.

Mr. A. B. MITCHELL showed (1) a case of epithelioma of the tongue, in which the trypsin treatment had just been started. He proposed to show the same case in a month, so that members may judge of the progress, if any. (2) Four cases of gastro-enterostomy which were operated on during the last six weeks, all doing well.

Drs. W. B. McQUITTY, ROBERT BOYD, and BLAKELEY showed two cases of General Paralysis.

Dr. J. S. MORROW showed a case of exophthalmic goitre.

Dr. CECIL SHAW showed (1) a case in which he had done laryngotomy for papilloma in a child, *æt.* 4. The operation was done nearly a year ago, and there was no sign of return. The voice was strong but rough and hoarse. (2) A case of periostitis of the orbit.

Dr. THOMAS HOUSTON showed (1) a case of Psoriasis treated with thyroid extract. The case was one of general psoriasis of the trunk, arms, and legs, in a child. It cleared up in a few weeks under treatment, but relapsed in a day or two, when treatment was stopped, and cleared again when it was resumed. (2) A case of severe Anæmia in a boy, *æt.* 12, whose sister, *æt.* 10, is at present being treated in hospital for an exactly similar condition. In appearance the case closely resembles one of pernicious anæmia, though a blood count does not bear out the likeness.

Mr. T. S. KIRK showed (1) a case of spindle celled sarcoma of the jaw, incompletely removed by operation and subsequently treated by X-rays with complete disappearance of the growth. (2) A case of severe injury to the fore-arm—compound fracture of the ulna, compound dislocation of the elbow, and extensive ablation of the skin of the fore-arm, treated successfully by extensive skin grafting.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. GERMANY.

Berlin, February 17th, 1906.

At the Verein f. Innere Medizin, Hr. J. Orth spoke on EXUDATION CELLS IN GENERAL AND THOSE OF VARIOUS FORMS OF MENINGITIS IN PARTICULAR.

After a historical retrospect, he went on to say that by pus corpuscles was understood the cells of acute inflammatory exudation, and therefore exudation cells. It was certain that in the majority of these cells exudations, neutrophile leucocytes were present. Many were of opinion that there was no difference between pus cells and leucocytes. The teaching of Rindfleisch and Cohnheim formed the basis of that view from the transmigration of leucocytes from the

blood vessels. Two observations led to the history as to this view. (1) Experimental observation: Dead corneal membrane provided with excitors of inflammation was introduced into the body of the living animal, and showed after a time the same appearance as the living cornea. Here it was objected that the cornea was not quite dead, and the tissue cells had perhaps recovered in the animal's body. In order to show the fallacy of this objection, the speaker had allowed the membrane to steep in a 10 per cent. solution of formal, then softening it so that fluid could permeate the tissues; it was then boiled in vinegar and cauterised with croton oil, and then introduced into the abdominal cavity of a rabbit. On removal, the membrane was certainly partially softened, but the lattice-work of the inflamed cornea could be seen in places beautifully marked. This inflammation in the dead membrane must have been caused by immigrating cells. By means of the new granula staining the granula of the leucocytes could be demonstrated in the pus corpuscles.

Besides the leucocytes, still other cells were found in the exudation. (1) such as covered the surface, epithelium cells, cover cells; (2) lymphocytes; (3) connective tissue cells, *i.e.*, not fibro-blasts but only such as appeared in the connective tissue, but not the connective tissue cells themselves; they were when freed very strongly phagocytic; the form of the macrophages were also found. Such cells were very numerous in the later stages of inflammation.

There were exceptions, however, in which leucocytes did not play the chief part. Here caseous or tuberculous pneumonia belonged, in which the exudative cells were not leucocytes, but large cells with round nuclei, and thus different from those of croupous pneumonia. These cells were first cast off epithelial cells. But not infrequently alveoli were found, the epithelium of which was completely retained, but a plug of such cells was found in the lumen of these alveoli. If the nuclei of the exudation cells were compared with those of the epithelial cells, they were found to be smaller. Finally, such cells were to be found in the lung framework, in the connective tissue. These cells were partly desquamated epithelial cells, but in part they were of other origin; they were wandering cells, not leucocytes, but lymphocytes. There were, therefore, then still other inflammatory exudations in which the leucocytes were not the essential part, as in tuberculous pleuritis and in purulent meningitis. Here clinical inquiry was in advance of pathological anatomy. It had recognised that the cell contents of spinal fluid varied in the different forms of meningitis, and it had drawn diagnostic conclusions from the fact (Quincke). This was naturally the same for exudation between the cerebral membranes. Here nothing could be determined macroscopically, but it could be microscopically. At any rate the most recent text-books of pathological anatomy left one in the lurch as regarded these specific differences. Here, then, was a hiatus for the filling up of which the speaker had already commenced an investigation, and had recently instituted an inquiry through Hr. Esparoni for determining the typical variations in the exudation cells. Twenty-five cases had been investigated, 10 of tuberculous meningitis, 15 of non-tuberculous meningitis; of the latter, 11 were cases of cerebro-spinal meningitis, 2 from pneumococci, 2 from streptococci. The two latter pairs showed themselves identical microscopically—much fibrine, leucocytes with ragged nuclei. In the cases of cerebro-spinal meningitis, fibrine played a much lesser part; it might be absent altogether; there were here further leucocytes with ragged nuclei with numerous degenerative changes; finally large phagocytes. In the tuberculous meningitis cases, these leucocytes played no part; on the other hand, there were numerous lymphocytes, larger and smaller. Where did these come from? In a photogram in which, therefore, all colour is excluded, we see in a vein large lymphocytes, and in another photogram we see a lymphocyte partly, and, even with a part of its nucleus, passing through the wall of the

vein; in fact, the same extravasation that lymphocytes made. It was, therefore, clear that there were tuberculous inflammations in which not leucocytes but lymphocytes were the exudation cells.

At the *Otologische Gesellschaft*, in a discussion regarding operation for empyema of the frontal sinuses, it was worthy of note that at last a protest was made against the *operirwahnsinn* (operative mania.)

When Ritter, in 22 cases, as well as the *Königliche Ohren klinik* had to record two deaths from post-operative meningitis, it was an earnest warning for restraint, considering the slight troubles arising from chronic suppurative disease of the frontal sinuses. Heine gave a note of warning against injuring the lamina cribrosa of the cribriform bone, and rejected immediate suture of the cutaneous wound. Herzfeld had also had good results from Kuhnt's operation, combined with a confessedly long after-treatment. Hartmann claimed that removal of the anterior wall of the sinus was unnecessary, and that the use of the sound and inflation with air was frequently sufficient to remove headaches for months. Schötz declared that mere suppuration was not an indication for operation. Herzfeld thought foetidity, in spite of washing out, was an indication. Ritter, in order to protect the lamina cribrosa now left the upper part of the median wall of the capsule of the cribriform bone standing.

AUSTRIA.

Vienna, Feb. 19th, 1906.

OSSEOUS CYST IN FEMUR.

Haberer showed a youth, *æt.* 17, with a thickened femur, presumably of cystic origin. Some ten years ago the patient was brought to hospital in ambulance with a fractured femur, where he was treated, and four weeks lay with it in extension apparatus, and finally three weeks in a gypsum bandage, after which he was dismissed perfectly cured.

At the fracture, on dismissal, there was a slight bend, but nothing unusual, as the patient affirmed his leg was stronger than ever it was before, which continued so till a year ago after very heavy exercise, when pain commenced in the upper third of the bone accompanied by slight arching with the convexity outwards.

In the region of the curve the bone had a spindle shape, hard, but not painful on pressure. This change had produced a shortening of the leg by a centimetre which caused him to limp when walking. The patient affirms that the limp has continued since he had pain in the leg, but the morbid process seems to be still progressing. The Röntgen rays show the right or sound leg to be normal, but the left in a state of *coxa vara*; in the region of the spindle great thickening of the bone was present with a spongy condition of the cortical substance, in many places perforations. The general appearance was that of an osseous cyst, but no other bone was affected, although a systematic search was made with the hope of discovering another centre, but in vain. Whether this isolated centre is malignant or benign or whether the neoplasm is of an inflammatory character there is no reliable testimony to confirm our opinion, unless an excision be made for histological purposes. Waiting, with repeated examinations by the Röntgen rays, may in time give some assurance, but the former method is to be preferred, as the cyst can be cleaned out and tamponned and the part given a chance to heal.

It is well to remember, however, that cysts occurring after fractures often heal spontaneously or become greatly reduced and remain quiescent and subsequently disappear altogether. If this view of the case were correct all interference should be avoided. Haberer at this point recorded several cases in support of this hypothesis, one of which was a female, *æt.* 19, who broke her left humerus, which was treated in the usual manner. About a year after she returned

with an osseous abscess near the seat of fracture, which was diagnosed with the Röntgen rays.

The arm was kept at rest, and in a short time the swelling began to recede. When examined last with the rays the cyst was still there, but greatly reduced in size.

ICHTHYOSIS AND PEMPHIGUS.

A young man, *æt.* 22, the son of a doctor, who since birth had suffered from *ichthyosis simplex fere universalis*, according to his father's observation, which remained stationary till he was six years of age, when a new crop of vesicles appeared on the skin but soon disappeared again, leaving the *ichthyosis* as before. He continues healthy. Six weeks ago the patient took ill with high fever and a repetition of the *pemphigus vulgaris* on the upper part of the body with intolerable itch. Resorcin, borax, etc., were applied with happy results. Since then other vesicles had appeared on the extremities, as if the skin had been macerated along the extensor surfaces. After a time they desquamated, leaving a red inflamed base. There were also epithelial erosions on the upper lips with typical mucous changes as in *pemphigus* and *ichthyosis*.

Newmann said the case was one of *pemphigus vulgaris* and not combined with *ichthyosis* at all. The locality was against the latter, being confined to the internal side of the joints, nates, and extensors of the three joints from which the epithelium was shed, leaving a flat smooth surface not to be found in a case of *ichthyosis*.

HUNGARY.

Budapest, Feb. 19th, 1906.

At the last meeting of the Interhospital Association, Dr. Vamosy delivered a lecture on the

PREVENTION OF OPERATIVE INFECTION.

He made a series of experiments on guinea-pigs for the purpose of determining the possibility of increasing the resistance to peritoneal infection with the colon bacillus. For this purpose, like Borchard, he used injections of nucleic acid, horse serum and physiological salt solution. Subcutaneous injections with the two latter were sufficient to protect the animals against subsequent infections of fatal doses of the colon bacillus. The nucleic acid was not only inefficient, but gave rise to a severe local reaction. The solutions were also injected into the peritoneal cavity and all three substances applied in this way were efficacious in increasing the resistance of the subject, so that two or three times the ordinarily fatal dose of bacteria could be survived. It was found that the highest point in the resistance occurred about forty-eight hours after the injection, which is much later than the highest leucocytosis. The protection was found to last about four days. The lecturer believes that the possibility of infection from laparotomy may in this wise be considerably diminished.

Dr. Palotai related his experiences with spinal anaesthesia in obstetrical cases.

The good results which were described by Professor Martin, induced Dr. Palotai to experiment with the injection of cocaine, preceded by adrenalin into the subarachnoid space in women about to give birth. The anaesthesia frequently lasted up to three hours, and not rarely extended as far as the clavicles. After-effects, with the exception of vomiting, he did not notice. Hypodermic injections of caffeine have recently been recommended to prevent vomiting, but in the speaker's hands, they were without effect. It seems that patients, weak and advanced in years, possess a special tolerance for cocaine, so that this may often be substituted with advantage for chloroform. Application of forceps, version, and perineal suture can be done without inducing pain, but it is undeniable that the contraction of the womb and of the abdominal muscles is somewhat retarded. Involution of the uterus and the formation of milk are not interfered with.

AID FOR CONSUMPTIVES.

A Bill has been prepared by Dr. Kuthy Dessz

which is shortly to be introduced into the legislature by a medical man. The Bill provides for an appropriation of about £40,000 for the establishment of camps, hospitals, and dispensaries in a section of not less than 700 acres in the healthiest part of Hungary. They are to be established under a tuberculosis commission of six, and are to accommodate at least 200 patients at all times. The minimum period of treatment of each patient is to be three months.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

QUEEN'S COLLEGE.—Dr. Wm. Mair has resigned the post of Riddel demonstrator in Pathology, and has gone to act as assistant to Professor Lorrain Smith, at Manchester University. The post, which is worth £150 per annum, is now open. A complete list of subscriptions to the Better Equipment Fund is now published, the total amount being over £70,000. The Council has resolved to spend about £300 on procuring new microscopes of the most recent type for the various scientific departments of the College.

PUBLIC HEALTH.—The report of the medical officer of health last week showed a rather serious state of things in the city. The cases of typhoid reported the previous week were 24, as against 12 in the week before, and seven in the corresponding week last year. There were 35 cases of scarlatina as against 12 the corresponding week last year. It was said at the public health committee that the regulations concerning the notification of infectious disease are not being strictly observed, and it was arranged to call the attention of the medical men of the city to the necessity for observing them.

HOME OFFICE APPOINTMENTS.—The inspectorship of factories held by the late Dr. Henry Purdon has not been given to a single medical man, but has been divided between three. Dr. Charles Milligan, who held the inspectorship at Ligoniel, a manufacturing village on the outskirts of Belfast, has had his district extended so as to include part of the city, and two new men have been appointed, Dr. E. B. Purdon, son of the late inspector, and Dr. J. E. MacIlwaine. Among the comparatively small number of medical men in the city who had not applied for the post these appointments are very well received. Like his father and grandfather before him, Dr. Purdon may be relied upon to do his work quietly and conscientiously, without appearing much before the public eye. Dr. MacIlwaine, who was one of the most brilliant students of his time, and who after graduating with high honour and a gold medal in the Royal University studied in Vienna, Paris, and Berlin, will be fully competent to carry out any of the scientific inquiries into matters affecting the health of factory workers which are now in vogue at the Home Office.

LETTERS TO THE EDITOR.

THE DECAY OF FRANCE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The report on the health of Paris commented upon recently in your columns, forms only one of a great cloud of straws which indicates beyond doubt the direction of the wind in France. Paris does not stand alone as an example of neglect of sanitation. The same conditions prevail throughout, from small villages to great towns. All the latter are below the level of German or English cities, whilst some of them, such as Marseilles and Toulon, display a truly oriental disregard of the fundamental necessities of sanitation. Paris has a huge debt incurred in rendering the city beautiful, in providing the outside show which dazzles the foreigner, gratifies the vanity, and satisfies the æsthetic sentiments of the people.

All beneath this outward show is rotten; and in spite of the superb climate which enables the inhabitants to spend much more time in the open air throughout the year than is possible in London or Berlin, the mortality shows, as you point out, an appalling total. The preventable sickness in the French army, mainly tuberculosis and typhoid, diminishes its strength to the amount of a corps—at least twenty thousand men. The same diseases in the German army are comparatively trivial; and seeing that the Germans have nearly twice as many men to draw upon, the loss of strength is more than merely serious. It helps to complete the humiliation of the nation, to make more plain the fact that without allies she would be at the mercy of her hereditary foe. Knowledge of their powerlessness drove the French to make their cowardly, immoral, and hypocritical alliance with the Russian Government—a government that represents the absolute negation of every one of the fine ideas of which the French constantly and loudly proclaim themselves the champions. The bottom cause of the whole situation is to be found in a fact which has been fully discussed in your columns—the practice of limiting the number of children in families to one or two has, besides keeping the population stationary for two generations, led to the growth throughout the whole people of a spirit of narrow egotism essentially anti-social and anti-national.

I am, Sir, yours truly,
H. S.

"CRAMMING" IN EDUCATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some of your readers will probably have read the report in our leading dailies of the address by Sir William Anson to the Association of Technical Institutions. "He believed they had blundered over the common stumbling-block, and had forgotten the primary importance of asking what it was they wanted to produce," and Sir William's address was really a review of the errors which have been made of late years over the question of education. Sir William ought to reflect upon the part that he and his contemporaries played thirty years ago in the errors he was criticising. We seem to be engaged now in sad retrospection and in tracing the troubles of the present to the sources from which they have come. Now, Sir William's remark may be applied to the very serious and interesting question of the education of those who are preparing to practise medicine. A system of cramming for examinations has grown up, book work replaces practical teaching, and there is no doubt but that most of our younger men are not prepared, as they ought to be, for ordinary "doctors' work when they get their legal qualifications to practise. It is well to recognise the fact that our Universities are not the best schools for ordinary practitioners. Those three or four years are spent on work that is only fitted for men who are going to take up the highest line of practice. There is a tendency to over-value the right to affix such titles as are given by the letters after a name, as M.B., M.S., &c., &c., and too much importance may be attached to these by young students, and parents anxious to start them well. Many live to find out that time and money may be spent to no purpose, and this subject might well receive attention in your journal.

I am, Sir, yours truly,
R. L.

AN IDEAL MEDICAL JOURNAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As a constant reader for fully thirty years, I congratulate you on the improved form which your paper has gradually assumed. The hypercritical can always find fault, but I am sure the impartial reader must admit that the MEDICAL PRESS approaches more closely than any of its contemporaries to the ideal of what a weekly medical journal ought to be

It is in every department clear, concise, and sufficient. It gives everything that any practitioner can possibly need to know, and he has not the trouble of fishing it out from an encyclopædic mass of matter mostly superfluous, if not altogether useless. To suppose that bulk is synonymous with value is a mistake, and when one knows how slow is and must always be the progress of medical science and art, it seems evident that for the man engaged in the active work of his profession, the essence of things as you supply it will, rather than the raw mass, always be that which he can take in and assimilate with satisfaction.—I am, Sir, yours truly,
Feb. 15th, 1906. [AN OBSCURE PRACTITIONER.]

THE TRIBUNE AND QUACK ADVERTISEMENTS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir, As a medical practitioner of many years' standing I am delighted to note the stand you make against the encouragement given by the lay press to quacks and quackery. Without the aid of the press the whole brood of parasites would perish miserably in a short while. It is past my poor comprehension how the editor of a paper professing high moral principles can admit the advertisement of patent remedies and nostrums, and quackeries of all kinds. Coming down to the root of the matter it is a conspiracy to defraud the public got up between the quack and his aider and abettor, the newspaper proprietor. The latter shares the plunder in the shape of well-paid advertisements.

How is this evil thing to be scotched? First let us have a Royal Commission to lay bare the facts of this wicked business. Then let us amend the Medical Act so as to control irregular practices of the kind. Lastly, let us prosecute—as Roosevelt is doing—newspapers that insert the lying advertisements of quacks.

I am, Sir, yours truly,
A FULHAM G. P.
Feb. 17th, 1906.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I be allowed space in your next issue for a few remarks relative to your criticism of the advertisements appearing in *The Tribune* of February 8th. I desire at the outset to point out, notwithstanding your suggestion of incredulity, that a strict supervision is really being exercised over the advertisement columns. Every advertisement is examined with the result that I am able to refute absolutely your statement that "you find the usual proportion of quack medicine advertisements" in our columns. As a matter of fact, insertion has been refused to many proprietary articles, quack medicines, as you prefer to term them, and although *The Tribune* is a new paper, this refusal, besides being productive of personal animosity towards the paper, already represents a loss to the proprietor of many hundreds of pounds. We are told over and over again that the other daily papers without exception accept this or that particular advertisement we refuse, but our guiding principle is that if we find internal evidence that the article is *bona-fide*, we are prepared to insert it.

Naturally the medical press would wish to prohibit the sale of all proprietary articles without distinction as to merit, but after all is said, and human nature being what it is, if sufficient evidence is adduced that the cure of any particular disease has been effected by means of a proprietary article, one is apt to give the proprietary article a chance in other similar cases.

The aim of the proprietor of *The Tribune* is to produce a daily paper which shall at once be wholesome, accurate and above suspicion—the moral tone of the paper being gauged by the character of the advertisements as much as by the character of the news it carries. If, therefore, as we state in the notice to our readers, any article is shown to be inaccurately described in our columns, and consequently a fraud on the purchaser, we undertake to stop the insertion of the advertisement. This applies to all

advertisements, so that if you are able to furnish us with satisfactory evidence that the Anturic Bath Salts advertisement comes within this category further insertions will be cancelled.

I have been tempted to write at greater length than I intended but the subject is a very important one, and I am prompted to hope that in fairness to *The Tribune* this reply will be inserted.

I am, sir, yours truly,
23-29, Bouverie St., E.C. J. G. SPARKHALL.
Feb. 19th, 1906. Advt. Manager, *The Tribune*.

[The above letter arrived shortly before going to press, and we hope to refer to it fully next week. Meanwhile, we should like to ask the writer who is to decide what is "satisfactory" evidence as to the merits of any particular preparation? Is the vendor, for instance, competent or any of the *Tribune* staff?—ED. MEDICAL PRESS AND CIRCULAR.]

SPECIAL ARTICLE.

THE HEALTH OF THE NAVY.

THE Blue Book containing the Statistical Report of the Health of the Navy for the year 1904 has recently reached us. It is unfortunate that, as in the case of most Government publications, interest in the contents is greatly lessened by the long interval which has elapsed between the period to which the Report refers, and the time at which it sees the light. That the Director-General and his subordinates are not directly responsible for the delay in this case is shown by the fact that the Report was presented to the House of Commons as long ago as last August.

The returns for the total force serving afloat may be considered satisfactory. Compared with the average of previous years, there are decreases in the ratios of cases of sickness, of invalidings, and of deaths.

The total force serving afloat, corrected for time, in the year 1904, was 110,570. The total number of cases of disease and injury entered on the sick list was 83,447, which is in the ratio of 754.69 per 1,000, being a decrease of 118.07 per 1,000 as compared with the average ratio of the last seven years. The average number of men sick daily was 3,467.25, giving a ratio of 31.35 per 1,000, and showing a decrease of 5.22 in comparison with the last seven years' average. The total days' sickness on board ship and in hospital was 1,269,015, which represents an average loss of service from disease and injury of 11.47 days for each person, which is a decrease of 1.84 in comparison with the average of the last seven years. The total number of persons invalided was 2,511, which is in the ratio of 22.7 per 1,000, and shows a decrease of 7.28 in comparison with the average of the last seven years. Deaths number 493, a ratio of 4.45 per 1,000, a decrease of 1.01 per 1,000 as compared with the ratio for the last seven years.

Of the general diseases appearing in the sick list the following are the most important: Influenza, 1,586 cases; malarial fevers, 693; tubercular diseases, 456; Mediterranean fever, 430; enteric fever, 226; dysentery, 133; parasitic diseases, 4,289; rheumatism, 2,361; syphilis, 6,219; and gonorrhœa, 6,039. In addition there are 1,035 cases classed as "other continued fevers." The rate for venereal disease shows a slight decline from the average, but a rate of 110 per 1,000 is still unpleasantly high.

An interesting feature of the Report is the valuable scientific matter in the Appendix, in the form of papers by various naval surgeons on subjects of pathological and practical importance, at which they had worked during the year. Malta fever has attracted much attention of late, and there are four papers dealing with it from different points of view. Fleet-Surgeon Bassett-Smith gives an account of some useful experiments bearing on the growth of the specific organism outside the body, and he also discusses the distribution of the disease in the Fleet. Staff-Surgeon Shaw gives a clear and excellent account of the agglutination

reaction in Mediterranean fever, while Fleet-Surgeon McNabb discusses symptoms and treatment. Caisson disease is the subject of careful papers by Fleet-Surgeon Mourilyan and Fleet-Surgeon Barrington. The curious condition of eczema produced by exposure to "Ningpo varnish," is described by Staff-Surgeon Boyden. These scientific papers deserve a better fate than interment in a Blue Book.

REVIEWS OF BOOKS.

THE RELATIONS OF MEDICINE TO OTHER ARTS AND SCIENCES. (a)

THE volume before us consists of a series of twelve lectures, some of which were delivered by the author at the University of Berlin, on the subject of medical "Kulturgeschichte," which, as is pointed out in the introductory chapter, was defined by Stricker in 1865 as the "boundary zone between practical medicine and many other arts and sciences," and which the author largely interprets as "the relations and connections between medicine and other branches of knowledge." The subject is, of course, an enormous one and full of interest, and no more than the mere fringe of it can be adequately discussed in the book before us, which contains only a little over 100 pages. The writer is, however, apparently a master in the matters of which he deals and is deeply learned in the traditions of medicine and in the philosophical bearings of its folklore. He is, in consequence, able to present a narrative which is no mere chronological statement of the phases of medical thought, but which summarises the wider sociological influences which it has exerted, and shows how medicine itself has been affected by current ideas and by succeeding waves of thought.

The first relationship dealt with is that which exists between Theology and Medicine. To this, four chapters in all are devoted, one of which deals with "Homœopathy and the Mystic Tendencies of the Nineteenth Century." The origin of medicine as an art, a mere accumulation of empirical remedies in the hands of the priests, is discussed, and also the origin of medical charms and amulets. These last are derived, according to the author, from the Persian "Emanation System," and their influence finds expression in the words of the Evangelist who speaks of "The Word" as the reflection or image, the Son, of God. Astrology and alchemy are considered, with their hidden meanings, and in connection with the former, says the author "This science is not dead but slumbers, to awake again in our time of radium and radio-therapy, but with a modern aspect." The medicine of the Old Testament, and that embodied in various codes of ritual, is not neglected, nor is the conflict between rational medical ideas and some of the present Christian dogmatics passed over without remark.

In the next three chapters the connection between philosophy, the science of sciences, and medicine; between law and medicine; and between general sociology and medicine is reviewed, and considerable stress is laid upon the *rolé* which physicians in general have played as educators of their own and of other countries. In these and in the succeeding chapters, which deal with physicians as statesmen, poets and artists, the writer, to our mind, lays a little too much stress upon the material part which has been played by members of the profession, and too little upon the general influence on ideas exerted by the science as a whole. Finally the importance of mathematics and kindred subjects as an aid to the advance of medicine is insisted upon, and some specific instances of its value in statistical inquiries are given.

We have perused this work with real pleasure and can heartily recommend it to those who desire to take a wider view of the position and responsibilities of the medical profession in relation to the complicated

mechanism and motives of civilised life. Perhaps some enterprising publisher will bring it more within reach of the many by affording an English translation.

OBITUARY.

A. L. PEACOCK, M.R.C.S.ENG.

THE death of Dr. A. L. Peacock, of Lincoln, which occurred on the 9th, is regretted by a large circle of friends. The deceased gentleman came to Lincoln between twenty and thirty years ago as doctor to the Manchester Unity of Oddfellows' Friendly Society. In 1882 he was appointed medical officer to the workhouse, and was also appointed medical officer for the home district, which comprised several of the city parishes in the Union. Though able to attend to his private practice, he has not enjoyed good health for some years, and his death was not unexpected. Dr. Peacock was in his sixty-sixth year, and he is survived by a widow and two daughters.

FALCONER CLARK, M.R.C.S.ENG.

WE regret to announce the death at Dorking of Mr. W. Falconer Clark, who had practised in that town as surgeon for many years. Mr. Clark joined the old East India Company and served on the North-West Frontier and during the Mutiny. He was present at the Siege of Delhi and the Relief of Lucknow, and possessed two medals with four clasps.

CANON OAKLEY COLES, B.D., L.D.S.

THE death is announced of the Rev. Canon Oakley Coles, whose name was at one time well known in the dental and medical professions. Whilst a student he married the sister of the late Sir Morell Mackenzie. While practising in Wimpole Street, London, he produced his work on "Oral Deformities," and afterwards became lecturer, dean to the National Dental Hospital, and editor of the *Monthly Review of Dental Surgery*, as well as the *Medical Examiner*. In 1886, being called to the ministry of the Church of England, he was presented at the house of Sir Edwin Saunders (the dentist to the Queen), with a testimonial and £100 from students and members of the dental profession. In 1899 he was appointed honorary canon of Canterbury, and in the following year received from the Archbishop the honorary degree of B.D.

F. J. C. PARSONS, M.R.C.S., L.R.C.P.LOND.

THE death occurred on the 9th inst. of Dr. F. J. C. Parsons, a well-known medical practitioner of Bridgewater. The deceased had been ailing for some considerable time, but his end was somewhat sudden. In addition to having lucrative private practice, Dr. Parsons had been for a number of years medical officer of health for the borough, and also the rural district. He was also an honorary visiting surgeon at the Bridgewater Hospital, in the making free of which he was a constant and earnest advocate. Until a few years ago Dr. Parsons was a keen cricketer, playing with regularity for the Bridgewater team. He leaves a widow, but no children.

GEORGE LOWSON, M.B.GLAS.

WE regret to record the death of Dr. George Lowson, Dundee, at Duncraig, on the 9th inst. The news will be received with deep regret by his many friends in Dundee and elsewhere. Dr. Lowson was a comparatively young man, and a native of Dundee. An unfortunate accident he met with two years ago, and which necessitated the loss of his leg, seemed so much to undermine his health that he never quite recovered his former cheerfulness and vigour. He studied in Glasgow University, and graduated in 1890 with the degree of M.B. and C.M. He was honorary surgeon to the Convalescent Home in William Street, and surgeon to the Hilton Lodge of Ancient Shepherds. He was laid aside from active duty only a week ago owing to a severe attack of heart trouble. Deceased is survived by a widow and three young children, for whom the deepest sympathy is felt.

(a) "Grundriss eines Systems des Medizinischen Kulturgeschichte." By Dr. Julius Feyer, Professor of the History of Medicine, Berlin University. Berlin: S. Karger. 1905.

MEDICAL NEWS IN BRIEF.

The Royal Academy of Medicine in Ireland. Address to the Lord Lieutenant.

On Friday last, the President and Council of the Academy presented an address of welcome to the Lord Lieutenant in person. The address, after congratulating His Excellency on his appointment, referred briefly to the past history and associations of the Academy, which was incorporated in 1882, being formed by the amalgamation of all the Dublin societies of standing which were cognate to the various branches of Medicine and Surgery, and which are now represented by its various sections. In 1887, on the occasion of her Jubilee, her late Most Gracious Majesty conferred upon it the title of "Royal." Its history has been prosperous and successful, as may be seen from the quality of the work in our annual volumes of transactions. That its foundation principles are good is shown by the fact that the Medical Societies of London are at present negotiating a movement of the same character that resulted in our foundation 24 years ago. His Excellency in reply, referred to the statement that the Academy was formed of the societies which formerly existed, and said that it was also very interesting, and very gratifying, to observe the token of the success of amalgamation—namely, that the medical societies in London are preparing for a movement of the same character as that of the Academy. It is obvious also that the two branches of the great professions to which, I understand, you furnish elements of help and sources of assistance in the most practical way, combining as they do science and the application of science in a most important and practical way, cannot fail to derive much advantage from such a body as yours, ready at all times to facilitate in promoting their ministrations. I thank you heartily for the kind expressions of goodwill towards Lady Aberdeen and myself, for our health and success while in Ireland. His Excellency hoped that with the healthy air of Ireland, and with a tolerably tough constitution, he might not have occasion to resort either to the scientific or the administrative side of the medical profession. But the more he met the members of the profession on another footing the better he should be pleased. The deputation shortly afterwards withdrew.

The Dental Hospital for Ireland.

The annual report of this hospital shows that the work it has done during the past year has been very considerable, the number of cases treated exceeding the large total of the previous year, being 41,620, against 40,725. Of these 33,881 were dispensary cases, 4,474 fillings, 495 cases of irregularity, 148 patients supplied with dentures, and 2,558 operations under anæsthetics. It may be noted that the fees received from nearly 34,000 dispensary cases amount to less than 3,000 shillings, showing in this department alone some 31,000 cases treated gratuitously. The Board of the Hospital have decided to allow medical students who have passed their half to take a short course of instruction at this hospital similar to that given to Naval and Military Surgeons. This privilege will, we fancy, be largely availed of.

The Irish Local Government Board and Asylum Control.

We published a few weeks ago an account of proceedings in the King's Bench at the instance of the Local Government Board with the object of obtaining a mandamus against the Committee of Management of the Richmond District Asylum, Dublin, and its Resident Medical Officer Dr. Connolly Norman, to compel them to comply with the terms of the Public Bodies Order. On that occasion, the Board obtained a conditional mandamus on which they have not as yet acted. We now learn that the new Chief Secretary for Ireland has stated that if the Asylums will not contest the right of the Local Government Board to make certain

regulations, it should be possible to arrange the matters in dispute after a conference. With this object he has consented to postpone further action, and thus afford the Asylums interested an opportunity of resuming the negotiations which were broken off by that Board. As to the abstract of accounts, the Chief Secretary was much impressed by the importance of having these abstracts uniform. He suggested that they ought not to have any difficulty in furnishing the abstract desired, while at the same time keeping the accounts of the Asylum in the form found most suitable by the committee. We further understand that representatives of the various Asylums which have resisted the Order have now decided to meet in conference in Dublin to discuss the matter, after which their views are to be submitted to the Chief Secretary. The Public Bodies Order appears to have pleased nobody, and if the question of its adoption or rejection can be arranged in a friendly manner it will be a matter for congratulation.

Medical College in China.

A REUTER telegram from Pekin states that the Lockhart Medical College, named after the British pioneer missionary, and organised by the London Mission and the American Methodist, Presbyterian, and Congregational Missions, was opened last week. The ceremony was attended by members of the Diplomatic Body, while the gathering of high Chinese officials was unprecedented at an event of this nature. Na Tung, President of the Foreign Office, congratulated the committee on behalf of the Dowager Empress. Sir Ernest Satow, British Minister, Mr. Rockhill, American Minister, and Sir Robert Hart delivered speeches. The college has accommodation for 350 students.

Norwood Sanatorium.

THE Norwood Sanatorium, we learn, was acquired some eight months ago by Mr. Joseph Rowntree, whose enthusiasm for temperance reform caused him to acquire it in order to enable the medical treatment of inebriety to be placed on a scientific basis. Mr. Rowntree has already handed over to an advisory medical committee the control of all medical and medico-ethical matters. Among those who have already consented to serve on the advisory committee are Professor Sims Woodhead (Cambridge), Dr. Harry Campbell, Dr. Rushbrooke, Dr. Cope, Dr. Claye Shaw, Miss Mary Sturge, M.D., and Sir Victor Horsley. Each patient is assigned a separate room, and is treated, as Mr. Stark says, "like a guest." It is claimed that the special form of medical treatment enables the patient to conquer the drug-taking and drinking without being subjected to the physical tortures which accompany so many "cures."

Aliens in the Port of London.

DR. HERBERT WILLIAMS, Medical Officer of Health for the Port of London, who is the medical inspector under the Aliens Act, has reported to the Corporation that the inspection works very smoothly. Since January 1, 33 immigrant vessels have arrived in the Port of London, bringing 1,184 alien steerage passengers. These have all been medically inspected; 17 have been certified as "undesirable" on medical grounds. The Immigration Board allowed ten out of these to land and ordered the deportation of the seven others. As was expected, the number of "undesirable" aliens rejected on medical grounds has diminished, the various steamship companies having found it to their advantage to have all passengers medically inspected before allowing them to embark at the port of departure. Dr. Williams gives extracts of reports made by the sanitary inspectors as to the way in which some of the people are brought to this country and the accommodation provided for them. In one vessel from St. Petersburg,

carrying 305 alien steerage passengers, the vessel was in a filthy and offensive condition. The available air-space per head was only 60 cubic feet, and floor space eight square feet. There was no provision made for the separation of the sexes. The ventilation and lighting were unsatisfactory, the sanitary provisions insufficient, and in the event of bad weather the passengers had to be confined to their quarters, as the after main deck was entirely occupied by horses. In another vessel from Libau with 234 steerage passengers the state of things was even worse. The whole of the after deck was occupied by 147 Russian ponies. As these vessels were Russian, the Medical Officer of Health recommended that the facts should be reported to the Board of Trade and the Russian Consul-General in London.

The Honorary Fellowship of the Royal College of Surgeons in Ireland.

ON Saturday last the Royal College of Surgeons in Ireland conferred its Honorary Fellowship upon Surgeon-General Keogh, Director-General of the Army Medical Service; Professor Henri Hartmann, Surgeon-in-Chief to the Lariboisiere Hospital, Paris (*in absentia*); and Dr. A. E. Wright, Pathologist to St. Mary's Hospital, London. The ceremony of presentation was an interesting one, although perhaps it followed more closely the procedure adopted in a university than is usual in collegiate functions, and consisted in the introduction to the President of each candidate successively by the vice-president, who recalled, in an interesting speech, the special deeds of each new Fellow. The Lord Lieutenant honoured the ceremony by his presence. Subsequently the annual dinner of the College was held, and was very largely attended. Sir Arthur Chance, the President, presided. Numerous toasts and speeches followed after dinner, amongst the chief of the former being "The King," "The Lord Lieutenant," "The New Honorary Fellows," "The Guests," and "The President."

Important Medical Prosecution.

ON February 14th, at Bristol Police Court, Frank Lee, of the Bristol Electropathic Institute, Cumberland Street, was summoned that he, not being a registered medical practitioner within the meaning of the Medical Act of 1858, and the Medical Act of 1886, and the Acts amending the same, and not then being a person recognised by law as a physician, surgeon, licentiate of medicine and surgery, practitioner in medicine or an apothecary, did unlawfully pretend to be and take and use the name and title of "Dr.," thereby implying that he was registered under the Medical Act, and that he was recognised by the law as a Doctor of Medicine, or a practitioner of medicine, contrary to the Statute 21 and 22 Victoria, cap. 90. There were three summonses for the same offences, relating to January 5th, 23rd, and 26th. The magistrates were of opinion that the defendant intended the public to believe that he practised as a doctor to heal disease, that he wrongly called himself a doctor, and that he did this for personal benefit, thereby gaining his living. A fine of £10 and £5 costs were then imposed.

Bogus Death Certificate.

BEFORE Mr. W. J. Stewart, at Liverpool City Police Court, on the 15th inst., Hamilton Jolly, alias Joseph Fitzgerald, an elderly man, who had been practising as a medical man in various parts of Liverpool for several years, was charged on six informations with forging certificates of the cause of death for the purpose of the Births and Deaths Registration Act, 1874. The defendant, who was not legally represented, pleaded guilty. Mr. R. P. Cleaver prosecuted on behalf of the Registrar-General, and said he would submit certificates signed by the defendant whereby it would be seen that the signature was "J. Fitzgerald, L.K.Q.C.P.I." The cases of which complaint was made were only part of a large number of death certificates which had been received by the various registrars in the West

Derby Union. These, together with a number of vaccination certificates which had been handed in signed by the defendant, made it clear that a somewhat extensive practice had been carried on by the defendant. Jolly at present occupied premises at 59, Redrock Street, West Derby Road. According to the Medical Directory, 1906, the tenant was Dr. Joseph Fitzgerald, L.K.Q.C.P.I., but the defendant was the only person who attended any of the persons in regard to whom the certificates were issued. Dr. Joseph Fitzgerald resided in Erskine Street, and had been seen by vaccination officers in reference to certificates signed by defendant in his name. Jolly was not a duly qualified medical practitioner, and it was an extremely serious matter not only as against the law of registration, but the poor people who paid the defendant fees he was not entitled to receive. He might say that he believed that Jolly was a relation of Dr. Fitzgerald. Defendant, who had nothing to say, was fined £10 in each of two cases, £5 in each of the other four cases, and ordered further to pay £10 in cost.

Queen Alexandra Sanatorium.

LORD CHELSEA and Sir Joseph Leese, M.P., spoke at a meeting over which Dr. Huggard, the British Consul, presided, held at Davos-Platz recently in aid of the Queen Alexandra Sanatorium, Davos. The sum of £12,374 has already been subscribed, and £21,000 is still required for building and furnishing. The sanatorium is intended to enable consumptive persons of limited means to take advantage of the high mountain climate.

Methylated Spirit in Medicine.

A HERBALIST named William Edward Evans, carrying on business at Lowhill and West Derby Road, Liverpool, was summoned by the Excise authorities on two informations for having in his possession on November 28th an article capable of being used internally as medicine called "Stomach and Liver Mixture," in the preparation of which methylated spirit had been used, contrary to the statute; and for having in his possession bottles containing a mixture labelled "Anti-stomachic drops," which also contained methylated spirit. Mr. Cecil Simpson (solicitor to the Inland Revenue Department) explained that an officer visited defendant's premises and purchased bottles of two mixtures, which on analysis were found to contain methylated spirit. Mr. Quilliam appeared for the defendant, who admitted the offence, but pleaded that he acted in ignorance. A fine of £2 was imposed in each case, and £5 5s. costs.

Conjoint Examinations in Ireland.

THE following candidates have passed the Diploma in Public Health Examination as undernoted:—Mary Annie Griffin Iles, M.D., Univ. Lond.; Richard John Bertram Buchanan, L.R.C.P. and S.I., R.A.M.C.; Patrick Dwyer, M.B., R.U.I., R.A.M.C., and Charles Walter Holden, L.R.C.P. and S.I., R.A.M.C.; with honours. Roland Thomas Groves Aickin, M.D., Univ. Edin.; William Lucknow Bradshaw, L.R.C.P. and S. Edin.; Henry Lawrence Esmonde-White, M.R.C.P.I., R.A.M.C.; Hubert Rodney Ross Fowler, L.R.C.P. and S. Edin.; James Albert Gibson, M.D., Univ. Edin.; Ernest Sydney Hawthorne, F.R.C.S.I.; Robert Arthur O'Donovan, L.R.C.P. and S.I.; and Jacob Philip Zierooel, F.R.C.S.I.

A MEETING of the Assistants of the Society of Apothecaries will be held on Wednesday, February 21st, at 8 p.m., in the Court Room of the Society's Hall, Water Lane, Blackfriars, E.C., for the purpose of founding an Association, confirming constitution, and rules and enrolling members. Ladies and gentlemen desirous of becoming members, but unable to attend, will please communicate (if they have not already done so) with the hon. sec., Mr. Albert Howell, Hackney Dispensary, Rosebery Place, Dalston, N.E. The subscription is fixed at 2s. 6d per annum.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT LITERATURE OF PHYSIOLOGY AND PATHOLOGY.

Bacteriology of Acute Rheumatism.—Beattie (*Journal of Med. Research*, January, 1906) gives the results of experiments intended to support the view that the "micrococcus rheumaticus" is the infective organism of acute rheumatism. In particular, he directs himself to distinguish the organism from ordinary streptococci as regards pathological effects. With a culture of micrococcus rheumaticus obtained from the synovial membrane in a typical case of acute rheumatism, and with a culture of streptococcus from the vegetations of a heart valve in malignant endocarditis, series of parallel experiments were conducted. The results show that whereas the streptococcus tended to give rise to general septicæmia, the micrococcus caused endocarditis, polyarthritis, or chorea. There was no similarity between the pathological effects of the two organisms. Moreover, though closely resembling each other morphologically and culturally, the two organisms present certain differences, of which the most important is the greater vitality in culture of the micrococcus. R.

Typhoid Bacilluria.—Dods Brown (*Edin. Med Journ.*, February, 1906), sums up our knowledge of this important clinical condition, and adds the results of his own observations. Discarding results obtained prior to the differentiation of *b. typhosus* and *b. coli* in 1895, Brown shows that, taking the average from the returns of many investigators, of whom Horton Smith, Herbert, Vincent, Richardson, Petruschky, and Lewis are the chief, bacilluria obtains in 21.24 per cent. of all cases of typhoid fever. The percentages obtained by individual investigators, however, vary greatly, and this suggests that there cannot have been any uniformity of method; thus, Lewis places the incidence of bacilluria as low as 2.22 per cent., while Lesieur and Mahaud place it as high as 46.66 per cent. Dods Brown's return—based, however, on only 15 cases—is even higher, 53.3 per cent. There are, moreover, other discrepancies between the results of the older observers. There is, for instance, much difference of opinion as to the period of the disease when the phenomenon appears. Vincent gives the usual period as from the eleventh to the seventeenth day, and Lesieur and Mahaud found bacilli in the urine on the tenth day. Brown's earliest day is the 28th. The period of persistence is just as variable as the date of appearance. Petruschky found bacilluria seven weeks after the subsidence of fever, and Busing six months after cure. Gwyn reports one case in which bacilluria was observed four years after an attack of typhoid fever, and Houston a similar case in which the organism persisted three years. Debate has waged, too, on the question of the association of bacilluria with albuminuria, with pyuria, with roseola, and with the severity of the disease. Various theories have been held as to the pathology of the condition—(1) that the bacilluria causes nephritis, followed by bacilluria; (2) that the bacilluria is consequent on typhoid abscess in the kidney; (3) that the organisms pass by the shortest route from the rectum to the bladder; (4) that a few organisms pass through the kidney and thereafter multiply in the urine. This last theory is by far the best founded, and is adopted by Dods Brown. His conclusions are—(1) *B. typhosus* appears in the urine of typhoid patients in from 30 to 35 per cent. of cases; (2) in most cases it causes no symptoms; (3) bacilluria is frequently, but not invariably, accompanied by albuminuria and oliguria; (4) the bacilli appear in the third or fourth week, and persist for a varying time—weeks or months; (5) bacilluria occurs more frequently in severe cases of typhoid fever, but is of no prognostic

importance; (6) bacilluria gives no aid to diagnosis. The importance of the phenomenon from the point of view of public health is great. In all cases the urine should be destroyed as carefully as the fæces, and care should be taken to avoid pollution of clothes with urine. Before discharging typhoid patients from treatment, the urine should be examined for bacilli. R.

Enteric and Mesenteric Cysts.—Ayer (*American Journ. of the Med. Sciences*, January, 1905), in reporting one case, describes this rare condition. His case was that of a cyst in the posterior wall of the cæcum, as large as a duck's egg, and containing three or four ounces of clear, viscid fluid; a funnel-shaped process extended a couple of inches under the mesentery of the ileum. In a discussion of the general subject Ayer adopts the following classification (based on that of Dowd):—(1) Cysts arising from the glandular structure of the intestine:—These are usually multiple, and of small size (1-4 cm. in diameter); they contain mucin. Though they may occur anywhere in the intestine, small or great, they are most common near the ileo-cæcal valve; (2) Parasitic cysts:—These have apparently only been found in the mesentery, and not at all in the intestine. They are due to the tænia echinococcus, and resemble cysts of similar causation occurring elsewhere; (3) Embryonic cysts. These—the most common abdominal cysts—are of many kinds. (a) Remains of foetal organs Wolffian and Mullerian bodies, omphalomesenteric duct. There are many instances on record which can have no other explanation. (b) Snared-off pieces of intestine, Remak's and other diverticula. These are usually recognised by the wall being of similar structure to that of the intestine. In some cases the connection with the intestine can be traced. (c) Cysts arising from sequestrations of intraperitoneal organs. Of this condition there are many records. Misplaced pieces of liver and pancreas, accessory spleens, suprarenals, and prostates have been described. (d) Dermoids, common enough in the female, but apparently unknown in the male. (4) Cysts of the normally placed retroperitoneal organs:—These are common, the pancreas being most frequently the site. (5) Cystic malignant disease, rare in this site. The article is a concise summary of much scattered literature, to which full references are given. R.

Light as a Cause of Cancer.—Hyde (*American Journal of the Medical Sciences*, January, 1906) discusses the possible activity of light in the causation of some forms of cancer. He devotes himself altogether to the acknowledged relation between xeroderma pigmentosum and epithelioma. This rare disease, occurring in young children, is characterised by a hyperæmia of the exposed parts of the body, followed by pigmentation, growth of angiomas, and finally of malignant warts. Linna and others regard the chain of morbid phenomena as due to the weakened resistance of the skin of the child, to the more refrangible rays of the solar spectrum, the hyperæmia and pigmentation being endeavours to inhibit the passage of the ultra-violet and blue rays. Hyde thinks it possible that in other cases also actinic influences may be at work in the causation of cancer. Thus it is said that negroes are immune to superficial cancers, as are also miners working underground. Superficial cancer is said to be more common in country dwellers than in city folk, and as is well known, it is more common in men than in women. These facts point, in his opinion, to a higher incidence of the disease in those exposed to light. He finds parallel results in the case of X-rays, of Becquerel rays, and of the radiations of radium. It is quite possible that irritation by light, like other irri-

tations, may be an exciting cause of cancer, but we are hardly justified in carrying Hyde's suggestion any further.

R.

The Causation of Syphilis.—MacLennan (*British Medical Journal*, February, 3, 1906) publishes a preliminary note suggesting a possible developmental relation between the *Spirocheta pallida* of Schaudinn, and the *Cylorrhycle luis* of Siegel. In several films prepared from syphilitic sores, he has seen the bodies described by Siegel under this name. They appeared, however, in various stages of development, of which, apparently, Siegel has only observed one. Between some of these bodies and the spirocheta there was a close resemblance, and MacLennan thinks it possible that the spirocheta is merely another stage of the same organism. In some of his preparations he saw some of the bodies he describes invading the red corpuscles. A full report, accompanied by microphotographs, is promised.

R.

Cerebro-Spinal Meningitis.—Elser (*Journal of Medical Research*, November, 1905) gives a bacteriological report of 130 cases of epidemic cerebro-spinal meningitis studied by him in New York. In 109 cases the diplococcus intra-cellularis of Weichselbaum was found either in cultures, or in smear examinations of the spinal fluid. In 16, no organisms were discovered by any means. In the remaining 5, the organism was not found during life, but was isolated in pure culture from the spinal fluid after death. Cultures were made from the spinal fluid during life in 105 cases, with positive results in 86. In many cases, cultures had to be repeated frequently before positive results were obtained, and in many cases several examinations had to be made before the organism was found in cover-slip preparations of the spinal fluid. Of the 16 negative cases, 12 were only examined once; it is probable that repeated examination would have detected the organisms in most, if not all, of these cases. Mixed infections were uncommon. In two cases the diplococcus of pneumonia was found associated with the diplococcus intracellularis; in one the streptococcus was found in the kidney and spleen, and in another in the blood. Staphylococci were sometimes met with, but were supposed to be due to contamination. Blood cultures were made during life in 41 cases in which a positive bacterioscopic diagnosis had been made from the spinal fluid, with positive results in ten cases. Elser believes that with improved technique, the percentage of positive results would have been much higher. He regards the presence of the meningococcus in the blood as a sign of grave prognosis. In 6 out of 22 cases, the meningococcus was separated from the nose or throat. Cultures from the urine in 5 cases were negative. In the pathological anatomy as seen in the autopsies, the principal point of interest was a characteristic hyperplasia of the thymus and lymphoid structures in most of the fulminating cases, which was absent in the cases which ran a more protracted course. Elser regards the status lymphaticus as having a causal relation to the rapidly fatal issue.

R.

Mycotic Aneurism.—McCrae (*Journal of Pathology and Bacteriology*, August, 1905) reports a case of this rare condition, and discusses the etiology. In addition to chronic aortic and mitral endocarditis, and acute fibrinous pericarditis, there were five small aneurisms of the ascending aorta, with acute vegetative endarteritis of the surrounding intima. Perforation of one of these into the pericardium had taken place, with resulting sudden death. Two of the aneurisms had continuous with them sharp slits in the intima, as clean and definite as if cut with a knife. In the infiltrated tissues at the bottom of the aneurismal sacs were numerous diplococci, both in the cells and between them. As the autopsy did not take place till seventy-two hours after death, cultural experiments were of no use. Two possible modes of development of such lesions are considered: (1) a primary local infection of the intima with ulceration, the ulceration spreading

into the media and causing an infiltration of aortic blood between its layers, and ultimately through the adventitia; (2) an infection reaching the media by the path of the vasa vasorum, and there setting up an inflammation, the ulceration of the intima being secondary. As regards his own case McCrae thinks the first hypothesis untenable, since if the disease began in the intima we should expect evidence of ulcerative conditions confined to the intima; but direct infection of the intima is very rare, although the presence of bacteria in the blood-stream is common. To explain the sharp-cut lines, McCrae suggests that the tissues had undergone hyaline change, rendering them brittle, and that a sudden increase of pressure from any cause is sufficient to cause a sharp cleft. The sequence of events in such a case as his he supposes to be (1) infective thrombosis of some of the vessels supplying the wall of the ascending aorta; (2) splitting of the wall of the aorta with subsequent rounding of the edges, or else simple ulceration; (3) contemporaneous formation of aneurism; (4) growth of fresh vegetations on edges of openings; (5) further splitting of aortic coat from peripheries of aneurismal openings; (6) rupture of an aneurism with death.

R.

Bacteriology of Empyema.—Emanuel (*Lancet*, January 13th, 1906) discusses various reports on the bacterial findings in empyema in children. There is a marked difference in the infective organisms as found in children, and in adults. Netter gives the following figures:—In adults, streptococci, 53 per cent., streptococci and pneumococci 2'5, pneumococci 17'3, staphylococci 1'2, tubercle and putrid 26; in children, streptococci 17'6 per cent., streptococci and pneumococci 3'6, pneumococci 53'6, tubercle and putrid 25'2. It will be seen therefore that whereas the incidence of tubercle is practically the same in children and in adults, the former are much more liable to pneumococcal infection than the latter. The figure (57'2) given by Vetter as the pneumococcal percentage, is much lower than that given by other observers. Koplik reports his experience as 60 per cent., Bythell as 65, Blaker as 88, and Still as 93. The average is probably about 75 per cent. Cases of pneumococcal empyema are either primary or secondary. The secondary empyema, i.e., associated with or following on pneumonia, is the more common, and there is even a question whether primary empyema ever occurs. Emanuel defends both on theoretical and empirical grounds, the view that true primary empyema is sometimes encountered. Speaking generally, pneumococcal infections are less virulent than streptococcal, but, nevertheless, they vary greatly. He classes them according to three types, varying in severity: (1) The infection is localised to the pleural cavity; (2) infection spreads by the lymphatics, and by direct extension, giving rise to pericarditis, peritonitis, or empyema of the other side; (3) pneumococcal septicæmia, giving rise to multiple abscesses, and distant infections. Although the tubercle bacillus is regarded as the infective agent in some 20 or 25 per cent. of the cases, it is notoriously difficult to detect it in the pus of empyema. According to some observers, the absence of any organism as the result of search suggests a tuberculous origin. Some help is given by examination of the cells in the exudate—"cytodiagnosis," as it is called. In tuberculous effusions, there is a preponderance of lymphocytes, and in acute infections of polynuclear leucocytes. In rare cases, other organisms—typhoid bacillus, colon bacillus, Friedländer's bacillus, diphtheria bacillus—have given rise to empyema. Staphylococci are often present, but probably not in a causal capacity.

R.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynaecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MARK TWAIN ON COD LIVER OIL.

This humorist recently attained his seventeenth birthday, and at a complimentary dinner given in his honour he said, in characteristic fashion, when replying to his health:—"Since I was seven years old I have seldom taken a dose of medicine, and have still seldom needed one. But up to seven I lived exclusively on allopathic medicines. Not that I needed them, for I don't think I did; it was for economy. My father took a drug store for a debt, and it made cod liver oil cheaper than the other breakfast foods. We had nine barrels of it, and it lasted me seven years. Then I was weaned. The rest of the family had to get along with rhubarb and ipecac and such things, because I was the pet. I was the first Standard Oil Trust. I had it all. By the time the drug store was exhausted my health was established, and there has never been much the matter with me since."

DE SENECHUTE (Swansea).—The compulsory retirement of members of honorary medical staffs of hospitals at the age of sixty is a somewhat moot point. As a matter of fact many men are capable of good work for a considerable time beyond that period. The general advisability of the rule appears to be based on good grounds. At the same time there is a great deal to be said on the other side.

AN INSANITARY RRECONSHIRE VILLAGE.

Vaynor and Penderyn District Council propose to spend £7,758 on sewerage works at Cefn, just outside Merthyr incorporation area, and a Local Government Board inquiry was held lately upon the subject. The clerk to the council explained that it was proposed to acquire land compulsorily for the bacterial tank system. Dr. Webster, J.P., medical officer, said that last year was the first for thirty years that Cefn village was free from typhoid; some of the houses wanted gunpowder under them. Cefn is within the area of Merthyr Parliamentary boroughs.

A WANDSWORTH PRACTITIONER.—Chronic nephritis is rare in childhood. When it occurs it generally follows some acute specific fever, but it may also result from gout, syphilis, and heart disease. Treatment is unsatisfactory. Hot-air baths are worthy a careful and prolonged trial.

DEFENCE (L. A. T.).—When Parliament has its hands less full—if that ever arrives—the question of the control of fraudulent patent medicines may possibly be considered. The remedy is clearly to prosecute for conspiracy to obtain money by false pretences. If a man sells a cough-cure warranted to cure—say, asthma, chronic bronchitis, and consumption, he is publishing a lie, and should be held answerable by the law for the consequences.

The Phagocyte! The Leucocyte!
(We seem to know them well by sight).
No wonder then we got a fright,
When told the story of their fight;
How it went on both day and night.
We argued were the savants right?
'Tis time the doctors should unite,
And make the microbes take to flight;
And seas that with infectious bite
Disturb our peace both day and night.

—A. D.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 21st.

ROYAL METEOROLOGICAL SOCIETY (70 Victoria Street, Westminster, S.W.).—7.30 p.m. Paper:—Mr. W. B. Newton: The Dispersal or Prevention of Fog.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. H. J. Paterson: Some of the results of Gastric Surgery. (Lecture II.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. E. Owen: Clinique. (Surgical.) 5.15 p.m. Lecture:—Dr. R. Hutchison: Dilatation of the Stomach.

THURSDAY, FEBRUARY 22nd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchison: Clinique. (Surgical.) 5.15 p.m. Lecture: Dr. R. Hutchison: Chronic Gastritis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—8 p.m. Dr. M. Dockrell: Treatment (Constitutional and Local in all its forms). (Chesterfield Lecture.)

FRIDAY, FEBRUARY 23rd.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m. Papers:—Mr. J. Sherrin: Three Cases of Intestinal Obstruction. Mr. H. W. Cannon: Three Cases of Appendicitis due to Transposition of Viscera. Mr. J. D. Malcolm: A Case of Appendix Abscess with Fevere Hemorrhage.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. H. J. Paterson: Some of the Results of Gastric Surgery. (Lecture III.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m. Mr. E. Clarke: Clinique. (Eye.)

Vacancies.

Bristol Royal Infirmary.—House Physician. Salary £100 a year, with apartments, board, and laundry. Applications to W. E. Budgett, Secretary and House Governor.

City of Winchester.—Medical Officer of Health. Salary £300 per annum. Applications to Thomas Holt, Town Clerk, Guildhall, Winchester.

Devon County Asylum.—Third Assistant Medical Officer. Salary £125 per annum, with board, residence, and laundry. Applications to Medical Superintendent, Exminster, Devon.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Leicester Infirmary.—House Surgeon. Salary £100 per annum, with board, apartments, and washing. Applications to Harry Johnson, House Governor and Secretary.

Manchester Port Sanitary Authority.—Medical Officer of Health. Salary £350 per annum. Applications to Arthur Holmes, Clerk, Bexley Square, Salford.

Royal Cornwall Infirmary, Truro.—House Surgeon. Salary £100 a year, with board and apartments. Applications at J. C. R. Crewes, 4 Parkvedras Terrace, Truro.

Torbay Hospital, Torquay.—House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to H. J. Paake, Secretary.

Trick County Lunatic Asylum.—Assistant Medical Officer. Salary £130 per annum, with board, apartments, and laundry. Applications to Dr. Miller, Hatton, Warwick.

Appointments.

BRODIE, DESBOROUGH, M.B., B.S. Lond., L.R.C.P. Lond., M.R.C.S.—Surgeon to the Tebury (Gloucestershire) Cottage Hospital.

BROWN, W. LANGDON, M.D. Cantab., M.R.C.P., Medical Registrar and Demonstrator of Morbid Anatomy to St. Bartholomew's Hospital.

CARWARDINE, T., M.S., M.B. Lond., F.R.C.S., Honorary Surgeon to the Bristol Royal Infirmary.

GEDGE, ARTHUR BYDNEY, M.R.C.S., L.R.C.P. Lond., Medical Officer for the Fifth District by the Devises Board of Guardians.

LITTLEJOHN, H. H., M.B., F.R.C.S. Edin., Professor of Forensic Medicine in the University of Edinburgh.

MAGGILLVRAJ, W. J. HOOKER, L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S. Glasg., Medical Referee to the General Life Assurance Co. for Districts of Rushmore and Fallowfield, Manchester.

MELLISH, JOHN STAFFORD, L.R.O.P. Lond., M.R.C.S., Surgeon to the Tebury (Gloucestershire) Cottage Hospital.

SCOTT, T. GRAHAM, M.R.C.S., L.R.C.P. Lond., Anaesthetist to the Dreadnought Hospital on Mondays.

Births.

CHAMBERS.—On Feb. 14th, at 27 Cheriton Gardens, Folkestone, the wife of W. F. Chambers, M.R.C.S., L.R.C.P. Lond., of a daughter

Marriages.

JESSETT—DOUGALL.—On Feb. 15th, at St. James's Church, Paddington, F. B. Jessett, son of Fred. Bowreman Jessett, F.R.C.S., President of the British Gynaecological Society, to Alice, daughter of the late Andrew Dougall, of 6 Queen's Gardens, London, W.

SMITH—ROSS.—At Lucknow, India, on Feb. 14th, Major A. G. Baird Smith, Royal Scots Fusiliers, to Mary Hamilton, eldest daughter of the late Surg.-Major J. Halyburton Ross, 39th Regiment, and Mrs. H. Ross, Southsea.

Deaths.

CLARK.—On Feb. 13th, at Dorking, Wm. Falconer Clark, M.R.C.S. L.S.A., late Medical Staff Indian Army, aged 75 years.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 2½s. per annum, post free. An edition is printed on thin plate paper for foreign and Colonial subscribers at 2½s. per annum, post free, if paid in advance, or 2½s. 6d. credit rate.

ADVERTISEMENTS

FOR ONE INSERTION.—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth, 12s. 6d. Considerable Reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the Publisher.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXII.

WEDNESDAY, FEBRUARY 28, 1906.

No. 9.

NOTES AND COMMENTS.

The Need for a Medical Assessor in Legal Cases.

WE have for many years advocated, as our readers know, the urgent necessity for the establishment of a medical assessor who will sit with the judge in cases in which medical questions are involved, as a naval assessor does in Admiralty cases. In April, 1901, the Royal College of Surgeons in Ireland passed a resolution calling attention to the need for this reform. The resolution was sent to the judges of the High Court in Ireland, and by them politely read and forgotten. In June, 1904, the Belfast Division of the British Medical Association discussed the matter, and expressed a unanimous opinion that the present system was a scandal, but no definite action was taken. We recall these facts because within the past week an Irish judge, Mr. Justice Ross, sitting in the Land Court, has, on his own account, called attention to the view which he has for some time held, that there should be a medical assessor in cases involving a difference in the opinions of medical witnesses. As matters stand at present, medical men are examined, cross examined, and paid as *ex parte* witnesses, and are then reproached for being so by the very men who have forced them into this invidious position. Should the Royal Colleges decide to take up again the reform of medical evidence, they would obtain valuable support from Mr. Justice Ross' statements in Court, and would we believe, be supported by the large body of medical opinion.

Infantile Mortality.

OF all the war-cries raised by public health enthusiasts, that of the infantile mortality is the most pathetic, as it is one of the most important. From various more or less philosophical standpoints the declining birth-rate dwindles into insignificance by the side of the swelling tide of the infantile death-rate. There are many curious facts connected with this absolutely unnecessary drain upon the life-blood of the nation. One would imagine, for instance, that more children would survive the first twelve months of existence if born in the highlands of Scotland rather than in the slums of Edinburgh and Glasgow. As a matter of fact, the chances are about equal. Dr. Baily, the Medical Officer of Health for Oban, pointed out in a recent lecture that whereas the child mortality of a town of that size should be about 45 per 1,000, the actual rate was 117—higher than Edinburgh and Perth and almost as high as Dundee. The lowest rate

he had to record was 37 in 1893, and the highest 119 in 1903. The rate for Argyllshire was 41 when that of Oban reached 112. Nearly all the babies were born healthy.

What Kills Them?

HERE, then, is a part of the country famous for native purity and wholesomeness, yet it is the precise spot to be distinguished by an appalling infantile death-rate. What kills these babes and sucklings? Dr. Baily is careful to inform us that the parents are healthy, and the children healthily born. The causes must be sought, therefore, in defects of environment. According to the medical officer of Oban, these unfortunates are simply not allowed to live owing mainly to carelessness, improper feeding and dirt—while underlying all is the terrible curse of alcohol. The picture thus presented may well give pause to the twentieth-century philanthropist. There is no need for him to send out missionaries to convert far-off nations while here at hand human beings are being sacrificed in hecatombs at the shrine of ignorance. The housing conditions of the poor Highlander are a disgrace to our modern civilisation. Government can, at any rate, put an end to that source of danger. Meanwhile happy the infant who is born away from the Scotch Highlands!

Oysters and Municipal Responsibility.

THE easy assumption of local authorities that they are free to poison the public at their own sweet will has of late years received sundry rude awakenings. The Lincoln sanitary authorities, for instance, have been forced to pay heavy damages to sufferers from enteric fever due to their polluted water supply. Now the proprietor of an oyster-bed has obtained an injunction and £1,500 damages against the Southend Corporation. The finding of the Court was, in point of fact, that the body in question had no common or statutory right to pollute the Thames estuary with sewage. This decision, if upheld on appeal, will materially strengthen the hands of sanitary reformers. It may be remarked, by the way, that if the Southend Corporation be answerable to the owner of the oyster-bed they must be logically responsible to any person infected by enteric fever from Southend oysters. Lastly, if it be wrong to pollute the estuary of the Thames, it must be far more culpable to contaminate the main stream, especially in its upper reaches

whence it is taken to supply Londoners with their drinking-water.

First Steps of the Toddler.

COMPLICATED as the problem of excessive infantile mortality may be, there are, nevertheless, obvious remedies that could be applied forthwith by any well-governed community. For instance there is the municipal *creche*, or day nursery for the tending of infants whose mothers are working away from home through the day. The good effected by this simple means is incalculable, and the organisation may be made partially self-supporting. Another great weapon at hand is the provision of pure milk by a municipal milk supply. The feasibility of such a system has been proved in many towns both at home and abroad. It means the substitution, at a cheap rate, of pure good milk in place of an adulterated and often contaminated unwholesome article. To secure a plentiful supply of pure milk for municipal babes is to strike at the root of things, and to lay the foundation of sound bone, brain and muscle for the next generation. Yet there is only one municipal milk supply in London!

Medical Inspection of School Children.

At a later age children are exposed to a thousand and one additional perils when they go to school. It needs less than Socratic wisdom to foretell that the aggregation of large numbers of children from the homes of the poorer classes will tend to foster and spread communicable diseases. That it has done so, notably in the case of diphtheria, is well known. That it maintains to a great extent the abnormally high rate of whooping-cough, measles and scarlet fever also seems more than likely. Yet it is only within the past few years that an attempt here and there has been made to secure the systematic inspection of board-school children. In London a specially-skilled and qualified inspector has been appointed in the person of Dr. Kerr. His field of work is wide and complicated. London school children, for instance, are riddled with ringworm. How many years will it take to rid our elementary schools of that gross infection?

LEADING ARTICLE.

THE TRIBUNE AND ITS ADVERTISEMENTS.

LAST week, shortly before going to press, we received a letter from Mr. Sparkhall, advertisement manager of *The Tribune*, disputing certain contentions contained in an article published in the MEDICAL PRESS AND CIRCULAR of February 14th. Mr. Sparkhall expressed the hope that in fairness we would publish his letter, and we may say at once that we were very glad to do so, both as affording our readers an opportunity of judging the question at issue after hearing both sides, and also as giving us the opportunity of illustrating certain great principles from a particular incident. We would like to preface our remarks by asserting that we have nothing but admiration for *The Tribune* as a newspaper; it seems to

us, as indeed we said in our original article, that *The Tribune*, by its general tone of responsibility and its absence of sensationalism, marks a healthy reaction from the "Americanisation" of journalism that has made such rapid strides of late years as to infect the whole, or nearly the whole, of the daily press. Politics apart, all thinking people will be prepared to admit that *The Tribune* is a welcome addition to breakfast-table literature. But by whom much is claimed, from him will be much required; and *The Tribune* makes a particular and special claim to the support of right-minded people, namely, that it exercises a strict supervision over its advertisement columns, and endeavours to prevent the insertion of any advertisement which is fraudulent, or offensive, or which does not accurately describe the article sold. As Mr. Sparkhall puts it in his letter, "The aim of the proprietor of *The Tribune* is to produce a daily paper which shall be at once wholesome, accurate, and above suspicion—the moral tone of the paper being gauged by the character of the advertisements as much as by the character of the news it carries." This is a high and noble aim, and we hope we have not so far lost faith in our fellow-creatures as to doubt the possibility of such a journal being carried on as a successful enterprise; but, undoubtedly, the signs of the times are not wholly comforting in this respect. If *The Tribune* is able to live up to this ideal, and to flourish in maintaining it, a valuable example will be established for its rivals and contemporaries. But is this ideal compatible with the insertion of high-flown advertisements of those goods which Mr. Sparkhall calls "proprietary articles," or which we should designate "quack medicines"? The particular article which we referred to in our original remarks we know nothing of scientifically or practically; and, indeed, it is better from the point of view of arguing the general question that we should not. We had never heard of it before, nor have we come across any reference to it since, but we would simply take the claims made by that article as an example of those put forward by its class. The question is really bipartite, Is it good (or moral) to advertise quack medicines? and, Are statements of the class quoted accurate descriptions of the article sold? Now, in answering the first, we want no better coadjutor than Mr. Sparkhall, for he says in his letter, "human nature being what it is . . . one is apt to give the proprietary article a chance in other similar cases." It is a quite a fair paraphrase of these words to say, "human nature being weak and credulous, and its possessors not being able to distinguish between the malady of A and the malady of B, men are apt to give to B the article that seemed to do A good, when he seemed to be suffering from similar symptoms, if that article be sufficiently held up to their admiration." That position we traverse. We say that the function of a moral journal should be not to take advantage of the weakness of human nature to obfuscate or confuse, but to lay itself out to show the better way and the true reasoning. Let us now come to the

definite statement quoted. We will only take one. "Whether the complaint (*i.e.*, rheumatism and gout) is in its early or advanced stage, the result is always the same, because XY completely eradicates the cause." Is it possible to predicate this absolutely of any known disease, from chilblains to cancer, or of any known remedy, from bicarbonate of soda to the Röntgen rays? It is flattering to speak of it even as an hyperbole. One remark made by Mr. Sparkhall shows an attitude of mind which is a common, and, we think, a mistaken, one. He says: "Naturally, the medical press would wish to prohibit the sale of all proprietary articles without distinction as to merit." Now, in writing that sentence, we should say "unnaturally." The medical profession, which is served by the medical press, are frequently gainers financially by the habit people fall into of having recourse to quack medicines, for disease is dallied with and allowed to run on while "proprietary articles" are given a "chance," and in the result chronic ill-health with prolonged medical attendance is incurred. But seeing the misery and incapacity thus caused so frequently, the medical profession and medical papers feel it their duty, against the gain to the pocket, loudly and frequently to protest against quackery in all its forms. We trust that this view of the case will appeal also to the proprietor and manager of *The Tribune*, and that they will succeed where most of their contemporaries have failed in meeting the high responsibility that rests on those who cater for the public's instruction.

A REVOLUTION IN THERAPEUTICS.

THERE was a delicate element of humour, not, we think, altogether lost on the chief person concerned, in the compliment recently paid to Professor Almroth Wright by the Royal College of Surgeons in Ireland. The function of a college of surgeons is, we suppose, the improvement of the art of surgery, and the upholding of the interests of the practisers of the art. If, however, Dr. Wright's recent discoveries are as far-reaching as he and others believe, then much of the necessity for the very existence of the art of surgery will disappear. If the advance party be on the right track, then the operating theatre is to give place to the laboratory, and the surgeon's knife to the vaccinator's syringe. The course of advance in serum therapeutics has, indeed, been so remarkable since the first crude attempts in organotherapy, that all that was necessary to increase their scope to the widest seems to have been supplied when Dr. Wright introduced his method for the estimation of opsonins. This term, which is a puzzle to many, is the name by which he designates those protective bodies produced in the serum of an animal inoculated with an infective organism which have the power of preparing the invading organism for phagocytosis. Where the protective reaction of the animal is good the opsonic index is high, and where it is poor the opsonic index is low. The determination of the opsonic index, though

resting on principles of the utmost simplicity, is a matter of somewhat fine technique. It is, in fact, the performance of an artificial phagocytosis under conditions open to observation. The practical utility of the possibility of determining the opsonic index of any serum is the power that we thereby gain of controlling the dosage of vaccines. According to Dr. Wright, one relative failure in the past in the use of such vaccines as tuberculin has been due not to any fault in the principle of the method, but to our inability to graduate our dose to the condition of the patient. As an overdose is likely not merely to fail to produce protective bodies, but actually to lessen their production, this is a matter of great importance. By the estimation of the opsonic index, we are able to time our injections so as to maintain a constant production of protective bodies. Dr. Wright and many of his disciples have applied this method of vaccination, guided by opsonic observations, with the greatest success in the treatment of local infections due to a great variety of infective organisms. The most notable instances are localised tubercle and staphylococcal infections, such as boils and acne. Detailed instances of the treatment of many such conditions were given by Dr. Wright in his lecture before the Royal College of Surgeons in Ireland. There seems little doubt that the method not merely has a great future before it, but that it actually opens up a new era in therapeutics. Though not likely just at once to interfere with the usual surgical measures for the treatment of local infections it should in all cases be used along with them, and in time it may come to displace them. While it is perhaps idle to speculate on the lengths to which Dr. Wright's discoveries may ultimately lead, it would be folly to overlook their importance or to allow any criticism of points of detail—and many points are open to criticism—to interfere with the granting of a thorough trial to his methods.

NOTES ON CURRENT TOPICS.

Doctors' Fees in Compensation Cases.

ONE item in the sumptuous bill of fare which the Government have prepared for the delectation of Parliament this Session is an Act to amend the Workmen's Compensation Acts. Notice of the introduction of this Bill has already been given. The subject of the right of workmen to compensation for accidents and the duty of employers to provide such compensation is a large one, but the principle being now admitted in all civilised countries the real difficulty comes in in drawing the exact line of demarcation. We may say that from our point of view it should be very rigidly drawn in a certain direction, namely, that which inclines towards doctors' fees. It goes without saying that when an accident occurs a medical practitioner is summoned, and as the case is always one of emergency he does not trouble to inquire as to who is incurring the liability for

his services. More often than not the summons comes from some casual witness of the accident who happens to have the longest legs or the stoutest "wind." At any rate, the doctor's time and skill are laid under requisition, often at great inconvenience to himself, and frequently he is unable to recover any payment for his services. A Government that recognises the liability of employers to provide compensation to their workmen cannot consistently neglect the accompanying liability for medical attendance. In France this liability falls on the employer, and in the new Act for this country it should be recognised as a definite charge on the employer or as a deduction from the sum payable to the workman. We trust the medical members of Parliament will strongly press this point when the Bill is under discussion.

Chemists' Shops and Limited Liability Companies.

ON the day of our present issue the famous Bill to restrict the poly-pharmacies of large firms will be presented to Parliament. Its aim is to restrict that form of trading so that each shop shall have a single responsible owner. It is promoted by the Pharmaceutical Society, and amongst its clauses are those that seek to impose registration upon chemists' shops and the limitation of dispensing to qualified persons. In all these points the Society will gain the hearty approval of the medical profession. The somewhat similarly-based proposal to restrict the practice of dentistry by companies, which is being advanced by the British Dental Association, may possibly form part of the forthcoming Medical Acts Amendment Bill. Obviously it is little use protecting the public against unqualified practitioners if the law can be evaded by organised trading ventures.

A Sanitary Authority.

IN view of the facts that came to light during the hearing of the case *Hobart v. the Mayor and Corporation of Southend*, in the Chancery Division of the High Court last week, we shall have to revise our ideas of what constitutes a sanitary authority. The plaintiff was a fish salesman in London, and he sought an injunction against the defendants restraining them from discharging crude sewage so as to cause a nuisance to him, and from permitting the discharge of sewage so as to cause water to flow over his land and to contaminate his oyster-beds. He also claimed damages for loss in his business resulting from the defendants' acts. After a protracted hearing, the judge found for the plaintiff and granted him an injunction and £1,500 damages. In the course of the case it came out that the plaintiff leased certain oyster-beds at Hadleigh Bay, near Southend, and the defendants discharged crude sewage into the estuary of the Thames, so that from the outfalls to Hadleigh Bay there was solid sewage and sewage scum, which, in the judge's opinion,

polluted the plaintiff's oyster-beds. The judge held that the defendants had no legal right to commit this nuisance and were, moreover, forbidden by a specific by-law under the Act for the protection of the fishery in the Thames from acting as they were doing. The plaintiff had suffered loss in his business, and the judge hinted that he would have given larger damages had it not been that the oyster-trade had suffered generally in consequence of the Winchester "scare." The danger of eating oysters contaminated by sewage has been clearly established, and none have taken a more active part in directing attention to this danger than the medical profession; it is, then, but bare justice to the oyster dealer to record how he is handicapped by those charged with the local administration of the public health Acts.

Christian Scientists' Privileges.

A GENERALLY-CONCEDED right, perhaps the only "right" which the State accords to a doctor, is that exempting medical men from jury-service. The same holds in New York, and it is amusing to note that a Christian Science healer in that State lately regarded himself so seriously as to neglect a summons to serve as a juror. The judge did not recognise the self-arrogated privilege, and the gentleman in question had to pay out a hundred-dollar fine. It is from facts like these that we gather hope that the righteous men in that Sodom of quackery—the United States—will eventually prove sufficient to save their country from the wholesale bamboozlement which at times seems to threaten to engulf the intellect of all its classes. Moreover, the *New York Times*, in commenting on the incident, goes so far as to say that it is inconsistent with common-sense to allow such a person as a Christian Scientist to serve on a jury at all, for a man who denies the value of all evidence is hardly likely to form an efficient adjudicator in a case resting entirely on evidence. We should not care to be parties to a law-suit tried before a jury containing even one Christian Scientist, and probably most of our fellow creatures would agree. If then, it be proposed that the followers of what our contemporary, the *Medical Record*, calls the "Eddyotic" creed claim exemption from serving on a jury, it would seem only in accordance with common humanity not to press them to take part in the proceedings.

French Brandy.

THE quantity of fraud that surrounds the sale of brandy has led to the formation of an association of the great brandy firms of the Cognac district, and from the report presented at the annual meeting last month, it appears to be in a flourishing condition. Forty firms have joined the Association, and a balance of over 50,000 francs to the good was shown as the result of last year's work. The fund is to be employed in the protection of the mark "Cognac" as a guarantee in all countries that the article so described is genuine brandy from that favoured district. From the medical point of view we welcome this

activity in their own interests on the part of the Cognac firms, as it coincides not only with the interests of the public, but in a special degree with the interests of patients for whom brandy is prescribed medicinally. With the commercial object of pushing the sale and popularity of brandy we have no concern, except as part of the general temperance question, which is one that appeals with great force to all modern hygienists. It is admitted that the English demand for brandy has fallen off of late years, but this is probably due to the increased popularity of whisky and not to any particular wave of temperance passing over these islands. It is, however, important to recognise that good and pure spirit is a *desideratum* from the point of view of the moral welfare of a people, and though medical men might wish to see brandy and whisky drunk far less than they are at present they would, certainly prefer to see sound articles consumed than the fiery and ardent poisons that are often foisted on to the unskilled and impecunious buyer.

The North Pole for Consumptives.

ONE would not be wrong in saying that surely no other disease has had so many different treatments recommended for it as consumption. From the vault of the heavens to the bowels of the earth every corner seems to have been ransacked to furnish some therapeutical contribution to lay on its insatiable shrine, and still the ingenuity of man manages to devise some surprise or novelty each week. There really seems a good deal to be said, however, for the advantages presented by the Arctic climate—in summer—for the treatment of early consumptives. To the *Journal of the American Medical Association* for February 3rd, Dr. F. Sohon has contributed a paper, accompanied by charts and photographs, advocating the northern regions for tuberculosis and some other chronic affections. The points that tell most in its favour are the complete absence of dust and other irritating particles, the sterility of the atmosphere, the prolonged sunshine, with its high actinic quality, and the stimulating effect on nutrition of the cool, dry climate. The proposal is one that does credit to the imagination of its originator, and, granted its practical feasibility under favourable conditions of travel and housing, early consumptives might certainly do worse than spend a few months in the higher latitudes. So far as we know, too, there are no Esquimaux Quarantine Boards with restrictive regulations.

PERSONAL.

THE proposed shooting expedition of the Prince of Wales in Nepal has been abandoned owing to the outbreak of cholera in a camp there.

THE first of the Dr. James Watson lectures under the auspices of the Glasgow Faculty of Physicians and Surgeons was delivered in the Faculty Hall on the afternoon of February 19th, by Sir Hector Clare Cameron, M.D. The subject of the lecture was "The Evolution of Wound Treatment during the last Forty Years," and Dr. W. L. Reid presided.

THE 149th annual general meeting of the Royal Maternity Charity of London, which was founded in 1757, was held at the Mansion House on the 20th inst., under the presidency of the Lord Mayor, who was accompanied by the Lady Mayoress.

Mr. J. TWEEDY, President of the Royal College of Surgeons of London, together with Dr. MacGillivray, President of the Edinburgh Royal College of Surgeons, were the principal guests at the annual dinner of the Association of Scotch Diplomates, held on the 23rd instant at the Trocadero, London.

WE regret to hear the report that Mr. Martin F. Ellis, M.A. Cantab., L.R.C.S. and P. Edin., has been severely wounded in the recent disastrous native attack upon a British force in Sokoto.

THE Duke of Abercorn, Chairman of the West London Hospital, will hold a reception at the *Conversazione* to be held in connection with the Post-Graduate School on March 14th next.

DEPUTY-INSPECTOR-GENERAL OF HOSPITALS AND FLEETS HENRY THOMPSON has been appointed Inspector-General of Hospitals and Fleets.

THE Honorary Fellowship of the Royal College of Surgeons of Ireland has been conferred upon Surgeon-General Keogh, C.B., Director-General of the Army Medical Service, and upon Professor A. E. Wright.

MR. OSKAR GRUNER, M.B. Lond., has been elected to the post of Clinical Pathologist in the Leeds University.

AT the annual dinner of the past and present students of the University of Durham College of Medicine, Dr. G. H. Hume was presented with a handsome testimonial on the occasion of his retiring on an age limit from the Royal Infirmary, with which he has been officially connected for a period of thirty-seven years.

SIR THORNLEY STOKER, President of the Royal Academy of Medicine in Ireland, recently presented an address on behalf of that body to the Lord Lieutenant of Ireland.

ON the 20th inst., Mr. Henry Morris was entertained at dinner at the Imperial Restaurant, London, by former house surgeons and dressers, on the occasion of his retiring from the active staff of Middlesex Hospital.

THE Gibson Scholarship in Pathology of the Society of Apothecaries, London, has been awarded to E. W. Ainley Walker, M.A., M.D., B.Ch. Oxon.

SIR WM. J. COLLINS, M.D., M.P., has been placed by the Treasury on the new permanent Advisory Committee on Education.

MR. K. S. WISE, M.R.C.S., of the London School of Tropical Medicine has proceeded to British Guiana to fill the new Government appointment of Bacteriologist to the Public Hospital, Georgetown. Mr. La Frenais, L.R.C.P. Edin., has been appointed a Government medical officer of the same Colony.

THE jubilee of the discovery by Dr. William Henry Perkin of the dye-stuff "mauve" by which the foundation was laid of the coal-tar colour industry, occurs this year. A public meeting was held at the Mansion House on Monday last, when the Lord Mayor proposed to open a subscription list for (1) presenting to Dr. Perkin for his lifetime an oil portrait of himself, to become the property of the nation at his death; (2) placing a marble bust of him in the rooms of the Chemical Society; (3) establishing a "Perkin Research Fund," for the promotion of chemical research, to be administered through the Chemical Society.

A CLINICAL LECTURE

ON

A CASE OF SECRETORY NEUROSIS OF THE STOMACH.

By WILLIAM J. DARGAN, M.D.,

Physician to St. Vincent's Hospital, Dublin.

THE condition we are to consider this morning is, I think, an unusual one, still, the patient's history as detailed by himself, and verified by the doctor who attended him before his admission, together with the observations made during his stay in hospital, should enable us to arrive at, at least, a probable conclusion. The patient, J. P., was admitted to St. Vincent's Hospital, October, 1905. He is a postman from co. Waterford, æt. 37, married, with two children. Up to the time of his present illness he seems to have been singularly healthy. He was exposed to severe wettings in the course of his occupation, but never was incapacitated from his duties even for a day. He has been a man of temperate habits both in eating and drinking, and never was addicted to alcohol. His dietary has always consisted of plain food, the only indiscretion being some indulgence in tea, but even this beverage never was taken in great excess. He never suffered from constipation or dyspeptic trouble. In July, 1904, he first complained of feeling unwell. He suffered then from diarrhoea, for which he could assign no dietetic error. The attack, after lasting for four weeks in a varying degree, passed away without seeming to materially affect his general health. From July on to Christmas, 1904, he continued pretty well, but complained at times of the bowels being somewhat constipated, and suffered from flatulency. On Christmas morning, without having eaten or drunk anything unusual, a very severe attack of vomiting set in. The vomiting was almost continuous, and very large quantities of fluid were ejected. The first day he states upwards of three quarts were brought up, and on subsequent days fully a quart was vomited, in fact, he says he "could not tell where it was all coming from." This condition lasted for ten days. At first the vomit consisted of food contents, later it was greenish, and towards the end of the attack was quite a clear fluid. Great nausea preceded and accompanied the vomiting. He experienced a sense of extreme exhaustion, being unable to stir from the recumbent position, and suffered from severe pains in the abdomen. He also complained of severe headache during the attack and great thirst. The ejection of stomach contents did not seem to give him relief to any extent, and any attempt to take fluids aggravated his condition. The retching would not cease for more than three or four hours at a time, and he would wake from sleep to suffer a renewed paroxysm. He attempted to take nothing but milk and water, but this was returned in thick curds. Throughout the attack he was constipated. At the end of the ten days he appeared to recover quite rapidly—could take food, and was able to resume his occupation. After three weeks of what he states was quite his normal state of health, he suffered from a recurrence of the symptoms, which again came on suddenly, lasted for about the same time, and as abruptly ceased. From that time up to the date of his admission to hospital, every month, with almost clock-work regularity, he suffered from like seizures, which lasted for about ten days, appearing and disappearing with the same abruptness. Since he first suffered from the attacks he has lost over two stone in weight, but in the intervals would pick up as much as three pounds. Between the attacks he felt quite well, was able to carry on his occupation, and could take all kinds of food. The onset of the attacks was quite independent of the kind of food taken. Before the spells of vomiting he sometimes experienced a splashing in the abdomen. During his

later attacks the fluid brought up was clearer than it used to be at first, in fact, as he says, often "like water." The vomited matter was never frothy. In the intervals he never suffered from headache.

Such is the history as given by the patient, and, as I said, verified by the local doctor. I will now tell you what observations were made since his admission to hospital. When he first came under my care he had just recovered from an attack, so that for some time we were unable to observe the phenomena of the seizure. His general condition did not present anything unusual, and did not differ from that in which you see him this morning. He is, as you see, a man of somewhat spare physique, but quite wiry, with well-developed muscles, and shows no appearance of cachexia. The heart and lungs are quite healthy. The urine is normal. The tongue is not furred, and the teeth in pretty good preservation. The liver dulness does not differ from the normal, and there is no distension of the abdomen. Palpation of the abdomen elicited a slight splash in the region of the stomach, and inflation through the stomach tube showed that the stomach extended slightly below the umbilicus. The splash is still sometimes present, but not so marked as before, and, as you see, inflation shows increase in the dimensions of the stomach. There is no tenderness or tumour to be made out in the abdomen. The knee-jerks are normal, and the eyes reveal no abnormality. Physical examination then shows us only that there is moderate dilatation of the stomach. Information was next sought from examination of the gastric contents. Since his admission he has had several test meals. The meal used was Ewald's, that is, a couple of slices of stale bread with a large cup of weak tea, without milk or sugar. This was given at 8 a.m. and removed by the stomach tube in about three-quarters of an hour. The contents were invariably found to be hyperacid. The indicator used for the total acidity was phenolphthalein, and for the free HCl, dimethyl amido-azobenzole, and Gunzburg's reagent, the titration being made with decinormal sodium hydrate solution. The acidity was almost entirely due to the hydrochloric acid both in the free and combined state. The organic acids were never present. The average percentage of total acidity was about '24 per cent. HCl., and the percentage of free HCl about '14 per cent. These figures, of course, only refer to the examinations made when the patient was in a comparatively healthy state between the attacks, but still the percentage of HCl is greater than we usually meet with in health. The patient was then put on a dietary containing a relatively large amount of proteid, such as lightly done meat, eggs, &c., given in small quantities at a time. He was given medicinally gr. $\frac{1}{4}$ nitrate of silver in water thrice daily. For over a month he continued well and put on weight; in fact, so well did he feel that he believed he was over all his troubles, and was anxious to return home, when suddenly he developed one of his old attacks. This began with uneasy sensations in the stomach, nausea, and some splashing was felt on movement. Then severe vomiting set in with pains throughout the abdomen, not localised to any distinct area, headache, and intense prostration. The temperature was not raised, and the pulse was about 100. A large quantity of fluid was brought up—fully a couple of quarts in a short time. This contained food contents, which on subsiding, left a clear supernatant fluid. The vomited matter gave a

strong HCl reaction, and was reserved for analysis, but unfortunately was removed accidentally before a titration was made. Milk was returned in thick curds. The stomach was washed out with plain water, but only slight relief was experienced. He was then washed out with a bicarbonate of soda solution which gave him instant relief. The nausea and vomiting began to subside, and after three or four washings with the alkaline solution the stomach was settled. The attack, instead of persisting for ten days, was ended in less than two, though for another two or three days he did not feel quite himself. He has remained free from the attacks since, under the following treatment:—He takes the ordinary hospital dietary, with rather more proteid than usual. Every third day the stomach is washed out and sprayed with a dilute solution of silver nitrate. He experiences no uncomfortable distension, the appetite is good, he is not constipated, and never feels any splashing. Examination of the gastric contents still, however, shows a hyperacidity—the HCl percentage averaging about the amount stated in the previous investigations.

Let us now consider the nature of his affection. The presumptive evidence goes to show that this man suffered from an affection of his stomach, for we can exclude such reflex causes of vomiting as disease or irritation of the other abdominal organs. His kidneys are apparently healthy; there is nothing to suggest renal calculus. The symptoms or physical signs do not point to gall-bladder, intestinal, or pancreatic trouble. He had no temperature or symptoms suggesting a toxæmia. Further, we may eliminate cerebral causes, such as brain tumour, as shown by the absence of headaches and the normal condition of his discs. He has no sensory or motor symptoms pointing to a cord affection, and his knee-jerks and pupil reflexes are normal, so we can rule out such conditions as the gastric crises of locomotor ataxy. His heart, lungs and liver are unaffected, consequently circulatory disturbance cannot explain his condition. Next, we may ask ourselves, could his condition be accounted for by a pathologico-anatomical lesion of the stomach? Here we have a difficulty in making his symptoms fit in with those attributable to a distinct lesion. Gastric catarrh could not explain the marked periodicity of the attack with the intervals of complete well-being. The question of ulcer or cancer can hardly be entertained in the absence of local tenderness and tumour, and the complete absence of pain and distress in the intervals. You saw that there was some dilatation of the stomach. Now we recognise that the causes of dilatation of the stomach are divided into the obstructive and non-obstructive. By the obstructive causes we mean those conditions where a mechanical obstruction is interposed to the passage of the stomach contents through the pylorus. This might be a constriction of the pylorus due to hypertrophic stenosis, a tumour at the pylorus usually cancer cicatrix of a former ulcer, constriction by bands or adhesions, the dragging of a displaced right kidney. Such causes would, however, be in constant action, and could not explain the periodicity of the attacks, and also, having regard to the fact that palpable physical signs are absent, may be disregarded. The non-obstructive causes of dilatation are those that interfere with the propulsive power of the stomach by producing weakness of its muscular coat, or such conditions as would cause over-distension of the viscus. Weakness of the muscular coat might result in the later stages of gastric catarrh and follow fevers or general debilitating conditions, such as anæmia or neurasthenia. Over-distension leading to permanent dilatation might occur from excessive fermentation in dyspeptic states, the taking into the stomach of unduly large quantities of food or drink, or, possibly, by the pouring out of an excessive amount of gastric secretion. Now, in the present instance there is no history of any condition that would produce muscular atony, and the patient's symptoms are not those that we should expect in an atonic stomach; in fact, the motor power seems to be

in no way impaired. There is no weight or fullness after meals, he is not troubled with flatulence or headache, and, moreover, the gastric functions seem to be quite normal in the intervals between the attacks. Again, we have no history of large quantities of food or drink at any time being taken, so that it is difficult to assign dietetic excesses as the cause of the dilatation.

We know that the stomach is supplied by three sets of nerve fibres—the motor, the sensory, and the secretory, and we know also that affections of either of these sets of fibres give rise to well-defined stomach symptoms. Now, either of these sets of fibres may be involved so as to affect their corresponding functions, whilst the nature of the irritation, though sometimes due to lesions of the brain or cord, may often be quite a mystery to us. We speak of such affections of the nerves producing deviations from the normal process of gastric digestion not based on pathologico-anatomical changes, as neuroses of the stomach. Thus we speak of the motor, sensory and secretory neuroses. The motor neuroses result from involvement of the motor nerves of the stomach, in which condition irregular impulses stimulate the muscular fibres. In this group we may have sudden spasms of the pylorus or cardia, the condition known as rumination, nervous vomiting, or the affection known as peristaltic unrest, when the contractions of the stomach are very constant and the food contents are often hurried through the pylorus with undue rapidity. Affections of the sensory nerves may give rise to neuralgic pain, which we call gastralgia, abnormal sensations of appetite, or an irritable hyperæsthetic condition of the mucosa. When the secretory nerves are involved the total secretion of the gastric juice may be greatly increased or lessened, and we speak of hypersecretion and achylia gastrica. Again, the constituents of the gastric juice may be secreted in relatively abnormal amounts. When the free HCl is in excess the condition is called hyperchlorhydria; when greatly reduced or absent, hypochlorhydria, or anachlorhydria. Let us now suppose that the secretion of gastric juice in the case before us through the action of the secretory nerves varied from time to time, that before the attacks and during, a very large quantity of a hyperacid juice was poured out, and I think we should be in a position to explain the patient's symptoms. The very acid secretion would act as an irritant to the stomach, producing the distress and vomiting, and at the same time the large quantity of fluid poured out would cause over-distension of the stomach cavity. If we regard the case as being one of a secretory neurosis of the stomach, we must suppose that the excessive secretion comes on at periodic intervals, and that between these intervals the stomach secretes in a comparatively normal manner. Now in a functional nervous disturbance it is fair to assume that this periodicity can occur. We have analogous conditions in migraine, and in many cases of neuralgia where the attacks often occur with a marked periodicity and subside in a definite time. Furthermore, in connection with the stomach itself we know that patients often suffer periodic gastric pain or gastralgia, so that there is no reason why the secretory fibres should not be similarly involved. When we refer to the literature of the stomach, moreover, we are borne out in our assumption for we find that such periodic cases of hypersecretion, though rare, do occur, and also that the hyposecretion is accompanied by a marked hyperchlorhydria. Reichman was the first to call attention to the periodic continuous flow of gastric juice, and named the condition gastro-succorrhœa continua periodica. His description corresponds very closely in symptomatology with the case we have under consideration, and the following account of the attack as given by Einhorn is worth quoting.

"In the midst of perfect health a sensation of discomfort is experienced in the gastric region, which is associated with restlessness. Soon afterwards the discomfort changes into a rather painful sensation and nausea appears. The patient is compelled to

occupy a recumbent position. The symptoms increase in severity, and in about an hour or two the nausea ends in vomiting of a large quantity of gastric contents. The patient may now feel a little relieved for a short time, but soon the same symptoms return. The appetite is entirely lost, and instead there is extreme thirst. The more the patient drinks the more, as a rule, he has to vomit. If he abstains from drinking the vomiting is less frequent, but persists nevertheless. Thus, as a rule, in the middle of the night or early in the morning, the patient has to vomit a large quantity of a watery liquid which is very acid in character, and either quite clear or greenish from admixture of bile. If this liquid be examined it will be found that free HCl is present in large quantities, as are the ferments (rennet and pepsin). After such an attack, frequently a constant desire to vomit persists, and the patient suffers from very violent and painful retching. Often a quarter of an hour after the last paroxysms, the patient's efforts to vomit cause a small quantity of clear yellow bile to be ejected. Even if the patient absolutely abstains from all kinds of food and drink, a few hours later a large quantity of gastric juice may again be vomited. The patient in this condition is hardly able to sleep for any length of time, as the pain awakens him soon after he has fallen asleep. The abdomen, as a rule, is sunken. The patient looks extremely pale and his extremities are cold. Severe headaches often accompany this train of symptoms, and constipation is almost a constant concomitant. After this condition has lasted for three or four days or longer, the nauseous feeling disappears, the pains subside and the patient experiences for the first time a desire for food. He is now able to eat without vomiting, and in a day or two feels like himself again. It is characteristic of this affection that the symptoms disappear almost suddenly, and the patient who seemed in a wretched state a few hours before may now appear nearly well. After a period of perfect euphoria varying from weeks to months or a year, or even longer, a similar attack may occur. The attacks may then either recur after the same period of time, or the intermissions of health may become gradually shorter, so that ultimately the patient has hardly recuperated from his last attack before a new one supervenes. The latter condition forms the intermediary stage between periodic and chronic gastric-succorrrhoea. During the free intervals the gastric secretion takes place either in a perfectly normal manner or hyperchlorhydria may exist. In either case, however, the stomach remains free from secretion in its empty state."

I think we are justified in placing our case amongst those described by Reichman as gastro-succorrrhoea periodica.

This case, however, seems to have been one of unusual severity, for not only have the attacks been very frequent, but they have lasted an unusually long time. The duration of the attacks in most cases is about three or four days, and only rarely—as in the present instance—do they persist as long as ten days.

As to the cause that initiated the attacks in the above case, I am quite unable to hazard a suggestion, as also whether they are due to discharges of central origin, or brought about reflexly. In the reported cases mental worry or excitement, or excessive brain-work are suggested as causes, but in the present instance there is no such history.

The prognosis in the condition is on the whole not bad. Cases of complete cure are reported, and, at any rate, the severity of the attacks may be markedly influenced by treatment, and their occurrence rendered less frequent. If neglected the condition would lapse into one of continuous hypersecretion, with permanent dilatation of the stomach and increasing exhaustion. In the present instance, having regard to the unusually severe nature of the attacks, it seems almost too much to hope that permanent cure can have been effected, and probably we may hear of subsequent attacks occurring in this patient.

The treatment of the attack may be carried out on the lines suggested above. Before it comes on, when the patient is beginning to suffer the preliminary nausea, a large dose of bromide is recommended. When vomiting has set in, lavage of the stomach with bicarbonate of soda solution gives relief. Copious draughts of suspensions of calcined magnesias, or sodium bicarb. may also be taken during the attack. In the intervals the patient should avoid irritating articles of dietary, especially alcohol, strong tea, coffee, &c., and should take plain food with some preponderance of proteid when hyperchlorhydria is present. Hemmeter states 30 gr. doses of strontium or ammon. bromide daily has an effect on the frequency of the attacks. He also recommends spraying the stomach with silver nitrate solution (1-1,000) from time to time.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of the journal. The lecture in next week's will be by Professor Hans Kühn, M.D., of the Allgemeinen Poliklinik, Vienna, on the "Cause and Therapy of Elephantiasis."

ORIGINAL PAPERS.

REMARKS ON GASTRO-ENTEROSTOMY, WITH DESCRIPTION OF A NEW CLAMP.*

By R. CHARLES B. MAUNSELL, M.B. (UNIV. DUB.),
F.R.C.S.I., Member of Council, R.C.S.I.,
Surgeon to Mercer's Hospital, Dublin.

THE operation of gastro-enterostomy has been prominently before the profession during the past ten years. Much has been written, and much spoken on the subject, so much, indeed, that some surgeons think that the last word has been said, at least for the benefit of our patients, and that further words will be more for the benefit of the surgeons. I do not acquiesce in this opinion, but think that there is much yet to be debated upon before this most useful procedure has definitely found a place with well-defined limits.

The literature of the subject being so voluminous, I will not discuss various methods of operation but merely the technique which I use in performing Von Hacher's posterior gastro-enterostomy. Neither will I labour the indications but will state that, in addition to the generally accepted indications, I have found most remarkable benefit follow where I have performed the operation for gastroptosis and gastreectasis, where, although there were no obvious signs of narrowing of the pylorus or of ulceration, yet examination of the gastric contents at various periods after test meals demonstrated the fact that there was distinct motor insufficiency. There can be no two opinions that by far the most immediate and most striking advantage follows in patients operated upon for definite pyloric stenosis; indeed, this fact has been so much impressed upon our American colleagues that many of them advocate closing or narrowing of the pylorus when examination during operation discloses that it is patent.

We must not always look for sensational results, and intelligent treatment after operation will ensure just as lasting benefit in the other conditions which I have named. Before describing the operation, I wish to draw attention to the great help in diagnosis and in determining our method of operative procedure which is gained by auscultation and auscultatory percussion over the abdomen and lower portion of the thorax, both before and after distension of the stomach by gas or air.

In operations upon the stomach the site and form of abdominal incision are of importance. The length of the primary incision must depend upon the size of the operator's hand.

* Read before the Surgical Section of the Royal Academy of Medicine in Ireland, January 12th, 1906.

I am totally opposed to the so-called exploration of the abdomen through an incision which will not admit more than one or two fingers, as I believe that this imperfect examination must lead to many a carcinoma being left *in situ*, as inoperable, when a more thorough search might have stimulated the surgeon to attempt its removal. A patient who will consent to an exploration will not give up his last hope because it is proposed to make a three-inch incision instead of the little hole advocated by some writers upon this subject.

It is fairly generally recognised that the site of the incision for gastro-enterostomy should be to one side of the middle line, the rectus muscle being split or drawn aside. Most operators make the incision through the sheath of the right rectus above the umbilicus, but I think there should be no fixed rule as when gastropexy and gastrectomy are present an incision on the left side, the lower end of which lies below the umbilicus, will give much more direct access to the viscera we wish to expose.

In operations undertaken more for exploratory purposes, or in which there is a doubt as to what operation may be necessary, the ordinary median incision is much simpler and much more easily adapted to the varying requirements of a difficult case.

The points of importance in making the junction between the stomach and intestine are (1) The form and position of the incision in the stomach; (2) the form and position of the incision in the jejunum; (3) the method of union; (4) the use of clamps.

The incision in the stomach should be two and a half inches in length, its direction oblique from above downwards and to the right, its position in the pyloric end of the moderately dilated stomach or at the most dependent portion of a flaccid and much dilated viscus. In the jejunum the incision should be of equal length to that in the stomach, longitudinal and opposite the mesenteric attachment; its position will vary in each operation, as it should be at a place which will lie easily in apposition with the stomach without either leaving a loop below the flexure or being dragged upon when the dilated stomach resumes its dependent position. I have frequently heard and read directions given in terms of inches measured from the duodenojejunal flexure and I am convinced that these definite directions account for many a "vicious circle."

The method of union which I adopt is by three separate rows of continuous No. 1 silk suture, the main blood-vessels having been separately ligatured as soon as the peritoneal coat had been incised.

During the past few years I have always used clamps as an aid in the performance of this operation, and I have found them of inestimable value, as by their aid the work is extra-abdominal, only very small portions of stomach and intestine are exposed, there is no chance of soiling by intestinal contents and the need for manual assistance is almost abolished. The clamps which I have used until lately are those designed by Moynihan, but I consider that, useful as they are, yet they might be improved upon. The faults which I have to find with them are that they are too clumsy, and they must be held in position by an assistant. I have designed a clamp which has been made for me by Messrs. Weiss and Sons, and which I have used in my last few operations, and I think it will prove useful to others as well as to myself. It is what might be called a twin clamp, and at first sight appears to be an enlarged Carwardine's intestinal clamp. On examination, however, you will see the peculiar interlocking points which keep the blades true when grasping a mass of tissue, the single slot which joins the two clamps together thus enabling the surgeon to separate them during the operation without unduly stretching the posterior rows of suture, and the fact that the forceps designed to grasp the stomach is almost twice as powerful as that designed to grasp the more delicate jejunum. The length of the blades is five inches, and that of the entire forceps nine inches. When these forceps are applied and locked together the parts are firmly held in the most exact position during the process

of suture of the viscera. I find it better either to separate the two forceps, or, indeed, to remove them altogether, as soon as the three posterior layers and the first anterior layer of sutures have been introduced, as this allows of infolding of the parts without tension, and also because a clamp at this period of the operation has ceased to be of any assistance. These forceps may be used either with or without thin rubber tubing drawn over the blades. Personally, I have not found rubber necessary.

With regard to post-operative troubles and mortality, we hear various statements.

The experience which I have gained from my own patients is that practically every patient vomits during the first few hours after the anæsthetic (ether). Most of these patients vomit a small amount of altered blood, more especially if a portion of the stomach had been rendered anæmic by the use of clamps. I have once seen a patient vomit sufficient fresh blood to cause anxiety—in this patient's case, however, clamps had not been used, or separate ligature of the vessels performed. Many patients vomit bile during the first twenty-four hours; some show this tendency for a few days. I have had one experience of "vicious circle"

in which I found the cause to be hernia of the jejunum through the opening in the meso-colon, and I was able to remove all symptoms by performing a lateral anastomosis between the two loops of jejunum. I am sorry to say that I have also seen one death in a patient who, but for a lack of judgment on my part, should have made an uneventful recovery. The particulars were as follows:—Male, æt. 55, had periodical vomiting for many years; had been washing out his stomach every few days for two years. At the operation, a dense fibrous stricture of the pylorus was found and a very much dilated stomach. Progress after the operation was good, except for complaint of a feeling of distension, until later in the evening of the second day, when repeated vomiting of small quantities of very much diluted bile and altered blood occurred. When I saw him next morning he was still vomiting, and rapidly passing into a collapsed condition with very frequent pulse. Upon passing a stomach tube, several quarts of fluid similar to that which had been vomited were drawn off, but the patient never rallied, although copious injections of saline solution were given subcutaneously. *Post-mortem*, it was found that the junction had been made at the pyloric end of the stomach, and that the greatly dilated cardiac end had sagged down full of fluid and completely kinked the new outlet, thus causing an acute intestinal obstruction. My mistake was that I had not rightly judged the position for the opening. It was unfortunate that in my absence some one did not wash out the stomach as soon as the vomiting assumed a continuous character, and distension of the stomach became obvious. I believe that if this had been done the obstruction might have been relieved, at least for a sufficient time, to allow of operative rectification of the faulty junction.

I will crystallise my remarks on the treatment of these troubles as follows: (1) If simple vomiting occurs, wash out the colon and give nourishment by the rectum. If weakness ensue give subcutaneous saline injections. (2) For hæmatemesis of such amount as to need treatment, give drachm doses of adrenalin chloride (1 in a 1,000 solution), if bile or other fluid is also present in the stomach wash it out with plain water before giving the adrenalin. (3) For bilious vomiting, wash out the stomach with plain water. (4) For "vicious circle" perform a lateral anastomosis.

In conclusion, I would say that the operation of gastro-enterostomy is one of the greatest blessings which has come to patients who suffer from chronic gastric disorders, but that it is not such a trivial operation that it should be advised until other methods of treatment have been fully considered and tried. I feel convinced, however, that where there are obvious signs of pyloric obstruction non-operative treatment is practically useless, and certainly no discussion as to possible medicinal treatment should be entertained if the symptoms suggest cancer, but all such patients should be immediately subjected to an exploratory operation.

A CASE OF

DISJOINTED PERSONALITY AFTER INFLUENZA.*

By ALBERT WILSON, M.D.

PSYCHOLOGY is often regarded by the legal profession as a medical myth. There is a condition of mental instability in which the *ego* becomes disjointed and separate units appear as distinct personalities. The *ego* is the focus or resultant of the combined mental units evenly balanced and correctly adjusted. The law distinguishes between crime and sin, and does not aim at the cure of crime. One disjointed unit may overshadow the whole *ego*.

M. B., the case to be described, was an example of multiple personality, in which all mental self-con-

sciousness was lost except to the one mental unit or personality which, for the time being, was manifest.

This unique case had nothing to do with hypnotism, crystal gazing, nor anything occult; nor was it a lapse of memory. It followed an attack of influenza.

What is its medico-legal value to us?

1. We must consider every mental variation.

2. It suggests a closer examination of the criminal classes on the subject of alternating personalities.

There is a specialism in crime which suggests multiple personality.

Case.—M. B., æt. 13. Easter, 1895. I call the normal, A; the abnormal personalities, B₁ to B₁₀. Each personality was a distinct life in itself, with no consciousness of any other. Each personality was continuous in its associations and memories. The handwriting varied in different personalities.

B₁. Mania, coma and trance.

B₂. Like a child, æt. 3. Quite ignorant, requiring re-education in all details.

B₃. A romping mischievous girl, æt. about 8, called "Nick."

B₄. Deaf mute.

B₅. Only remembers quite recent events.

B₆. Like a girl, æt. 12; well behaved and helping in house duties, but ignorant and too childish.

B₇. Remembers events of early infancy, even when two years old.

B₈. Mental confusion.

B₉. An imbecile and blind, but could draw perfectly by touch; no other personality could draw.

B₁₀. A degenerate.

These personalities appeared and disappeared without apparent cause for three years from March, 1895. The normal appeared in and out, but disappeared entirely. Since April, 1898, M. B. has been B₆, and is making her own living. She knows nothing of her normal life, or of her friends previous to Easter, 1895. The varying personalities are also so many blanks in the memory of her personal history. The true *ego*, M. B., seems gone for ever, yet no ordinary person could detect any abnormality in B₆.

The Cause.—Theosophy says a case of possession. I suggest a material explanation, based on the stratification of the brain cells and the circulating arteries. That there are planes of development, education, and intelligence, as years roll on, the earlier years relating to the deeper layers. Spasm of the arteries shutting off blood supply in different planes may cause arrest of function or memory. Thus a portion only of the brain will be active at such times, a unit of the whole, or as we may call it a personality.

At birth we are equipped with extra layers of undeveloped brain cells (embryonic) waiting their time of activity and education. These being unstable, are likely to undergo degeneration under the adverse social conditions of poverty, vice, and alcoholism. It results in personalities altered for the worse. The true *ego*, which Nature or Providence gave them, has been destroyed by "civilisation" and "Society." Does not the whole question merit more consideration? Why cannot we make a clinical picture of the criminal and learn to understand him?

THE OUT-PATIENTS' ROOM.

WESTMINSTER HOSPITAL.

Peculiar case of Perineal Neuralgia.

By PURVES STEWART, M.D., M.R.C.P.

AMONGST the out-patients was a well-known professional cricketer, æt. 30, who complained of intolerable perineal pain. He was a man of temperate habits and of powerful athletic physique. Two and a half months previously he began to have slight intermittent pain in the perineum, which was aggravated by walking. No apparent cause was assigned for this pain, and there were no symptoms either referring to the bladder or to the rectum. Two months ago when bowling at a cricket match he was seized with a

* Resume of Paper read before the Medico-Legal Society, Feb. 13th, 1906.

paroxysm of intense pain in the perineum spreading half-way along the penis, he had to stop bowling and walked home with difficulty; he went to bed and on the next morning he found himself unable to walk alone, but capable of walking if he rested one finger of each hand on some neighbouring object; this lasted for about three days, since when he had been able to walk quite normally, but if he walked or ran forwards or if he assumed the attitude of bowling pain at once recurred with great severity; on the other hand he could skip, jump, or run up or down stairs without pain. On examination the patient showed no physical abnormality; his gait was normal, the rectum and bladder were healthy, there was no varicocele or any other abnormality of the genito-urinary system, all his reflexes including the bulbo-cavernosus reflex were brisk. Dr. Purves Stewart said that there were several possibilities in the diagnosis. In every local pain it is the first duty of the physician to search for a local cause, in this case, however, there was no evidence of disease in the bladder, urethra, rectum, or genitals. He should therefore look elsewhere for the cause of the pain; some cases of tabes are associated with lightning pains which may affect any part of the body, but the normal condition of this patient's sensory, motor, and reflex functions, together with the fact that he had not had syphilis, excluded such a possibility. The history of the case was much more suggestive, he thought of hysteria; hysteria, he said, must not, however, be confounded with malingering; this man was not malingering, he had already consulted numerous physicians, and at last had taken a journey of many hours to London in the hope of obtaining relief from a pain which was preventing him from earning his living as a professional bowler. Hysteria, Dr. Stewart pointed out, was a real disease; the intermittency of the patient's symptoms and the fact that the pain was produced by running and bowling, whilst skipping and jumping were painless, strongly supported the hysterical theory. On this supposition Dr. Stewart proposed to make the attempt to get rid of the pain by producing a stronger local sensory stimulus, an example as it were of "the expulsive power of a new affection": a white hot Paquelin's cautery was therefore applied to the painful spot in the perineum; the original pain instantly disappeared. The patient retired to St. James's Park to verify his cure by going through the movements of fast bowling; he now found himself able to execute these without producing the old pain, and returned to the hospital to announce the fact. It was proposed to give the man a mixture containing bromide and valerian for a few weeks.

OPERATING THEATRES.

WEST LONDON HOSPITAL.

TRANSVERSE COLOTOMY.—MR. SWINFORD EDWARDS operated on a woman, *æt.* 53, who had been admitted four days previously with symptoms of obstruction. On examination a large mass was found in the rectum, which was evidently a fungating carcinoma. It was fixed and the finger could not reach above it. The patient was seen by Mr. Bidwell, who considered that an inguinal colotomy was the best course to pursue. The patient was, accordingly, taken into the theatre, and the usual incision was made for left iliac colotomy. The abdomen having been opened, whilst searching for the sigmoid colon a large escape of pus occurred with a distinctly faecal odour. This looked as though the bowel had given way in the neighbourhood of the growth. Under the circumstances the operator thought it best to postpone opening the bowel, merely contenting himself with a free drainage of this offensive abscess cavity. As the symptoms of obstruction still persisted forty-eight hours afterwards, Mr. Edwards

considered that the time had arrived for relief; he therefore proceeded to do a transverse colotomy; a longitudinal incision two and half inches long was made over the usual position of the inner border of the right rectus muscle just above and to the right of the umbilicus; on deepening the incision no muscular tissue was discovered, although the incision was fully one inch to the right of the linea alba. The peritoneum was opened and an examination of the abdominal contents made. The cæcum and transverse colon were found to be full of faecal masses and a line of induration in the lower part of the abdomen marked the upper limit of the abscess cavity before referred to. The omentum having been turned on one side, a loop of transverse colon was brought into the wound and fixed there by a couple of deep sutures made with thick silk, which were passed through its mesentery and each lip of the wound and tied tightly through a piece of rubber tubing; the bowel was also fixed by three or four fine silk sutures to the edges of the wound. The gut was not opened as Mr. Edwards thought the symptoms were not too urgent to admit of its being left for twenty-four hours. Mr. Edwards observed that transverse colotomy was a rare operation in his hands; undoubtedly, he said, the site of election was that in the left iliac fossa; if this, whether from extension upwards of the growth or otherwise, was not available he would open the descending colon through an incision at a slightly higher level than that employed in inguinal colotomy, employing the same method here—namely, by separating the various layers of muscular fibres in their respective axes; the descending colon would be opened about the same level by this operation, as when the old lumbar colotomy was performed, which was the operation in the seventies no doubt, he said, but few of the gentlemen present were old enough to have either seen it or performed it. He did not consider that the present case was a fitting one in which to open the descending colon on account of the contaminated condition of this part of the abdomen; by opening the colon where he had he got as far away from the infected area as was possible. He strongly objected to the formation of an artificial anus in the cæcum on account of the liquid state of the faeces, which in many cases produced much excoriation, and emaciation was also likely to follow. In the present case if symptoms of obstruction had been more urgent Mr. Edwards would have opened the bowel and inserted a Paul's glass tube. He also remarked on the fact that, although he had planned his incision to expose the muscular fibres of the right rectus, no muscular tissue was present owing to the wide interval between the recti, which were much attenuated. It was a lucky thing, he thought, that in his first incision he did not go into the bowel, as the abdominal wall in this situation was abnormally thin. The bowel was opened at the end of twenty-four hours, and the patient is doing well, the abscess cavity gradually closing up.

The Apothecaries' Hall of Ireland.—Address to the Lord Lieutenant.

ON Monday, February 19th, in the Throne Room, Dublin Castle, an address was presented to the Earl of Aberdeen from the Governor, Deputy-Governor, and Court of the Apothecaries' Hall of Ireland. The deputation consisted of Lieutenant-Colonel Adye-Curran (Governor), Dr. Seymour Stritch (Deputy Governor), Dr. Hanrahan, Sir Charles A. Cameron, Dr. A. Atock, Dr. J. M. Day, Dr. O'C. J. Delahoyde, Dr. J. D. Crinion, Dr. W. V. Furlong, Dr. W. Fottrell, Dr. R. Montgomery, Dr. S. M. Thompson, and Captain Adye-Curran, R.A.M.C.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON

MEETING HELD FEBRUARY 23RD, 1906.
The President, Mr. CLUTTON, in the chair.

MR. JAMES SHERREN read an account of
THREE UNUSUAL CASES OF ACUTE INTESTINAL
OBSTRUCTION.

Case I. was that of a male patient, *æt.* 31, who had a stricture, possibly congenital, at the junction of the jejunum and ileum. Enterostomy, with enterectomy three weeks later, was followed by recovery.

Case II. was a strangulated left duodenal hernia in a girl, *æt.* 13. There had been no previous obstruction. The hernia was reduced seven hours after the onset of symptoms, and the patient recovered. There were ten cases in the literature, four of whom had survived.

Case III. was a volvulus of the cæcum. The patient, a man, *æt.* 31, was operated on in seventeen hours after the onset of acute abdominal symptoms. The cæcum had to be resected for gangrene and the ileum joined to the ascending colon by means of lateral anastomoses. Corner and Sargent had collected fifty-seven cases of this accident, and had recorded five of their own.

The PRESIDENT remarked on the rareness of the cases and their interest. He commented on the very high mortality in cases of volvulus.

MR. J. HUTCHINSON, jun., had recently seen a case of volvulus of the cæcum with great laxity of the mesentery. The cæcum had passed under the mesentery and was found near the spleen. The patient, a young man, had made a good recovery. In the literature were nine similar cases of twisted small intestine and cæcum; four had been operated on, but only one had recovered.

MR. RAYMOND JOHNSON referred to a case that he had seen in Mr. Beck's ward at University College Hospital some years ago. The twisted cæcum was undone and then aspirated. The patient, a man of 49, died within twelve hours. The cæcum was enormously distended, and had passed beneath the small intestine.

MR. W. G. SPENCER related the case of an old man in whom a twisted cæcum was found near the spleen. Death occurred. He remembered seeing Mr. Walsham operating on a case of volvulus of the cæcum; the cæcum was stitched to the anterior abdominal wall without being reduced, and Nélaton's operation performed.

MR. A. E. J. BARKER had recently published a case in which the whole of the small intestines had twisted round a gastro-enterostomy point. He had had two cases of stricture of the small intestine, one being secondary to a strangulated hernia. It was possible that duodenal herniæ were more frequent than was usually supposed.

MR. SHERREN, in reply, said that he had had a case in which perforation had occurred above a stricture, the result of an old strangulated hernia. As regards the mortality in volvulus operations, two out of the five cases he had operated on in the past couple of years had recovered.

MR. H. W. CARSON communicated details of
TWO CASES OF APPENDICITIS ASSOCIATED WITH THE
PRESENCE OF OXYURIS VERMICULARIS.

The first case was that of a woman, *æt.* 10, who, on the day before admission to hospital, had been seized with violent abdominal pain and vomiting. The temperature was raised to 103° and a rigor had occurred. On admission, the temperature was 103·8°, pulse 110, respiration 32. Superficial tenderness was marked over the right side of the abdomen and right loin. There were no other physical signs. The appendix

was removed and a single oxyuris vermicularis was found, the mucous membrane of the distal half-inch being much congested, but not ulcerated. The second case was that of a woman, *æt.* 24, who was admitted to hospital on the second day of an attack characterised by severe abdominal pains and vomiting. Temperature 100·6°, pulse rate 118, respiration 28. Severe pain was complained of in both iliac fossæ, and there was much tenderness on examination, especially in the pelvis. There was no muscular rigidity, no sign of tumour, and the abdomen moved well in respiration. Three thread-worms were found in the appendix. There was no injection or ulceration of the mucous membrane. In neither case was there any history of thread-worms, nor have thread-worms been seen in the motions since operation. Mr. Carson contrasted the course and symptoms of these two cases with ordinary cases of appendicitis and discussed the question of the relation of the appendicitis to the presence of the parasites. He referred to Dr. G. F. Still's paper on 200 necropsies of children under twelve, in which the oxyuris had been found twenty-five times in the appendix without symptoms, and reported thirteen cases in which the appendix had been found to contain thread-worms after removal for appendicitis. He expressed the opinion that it was more reasonable to believe that the appendicitis in these cases were due to the presence of the thread-worms than to believe that their presence was merely a coincidence.

The PRESIDENT thought that the worms were merely coincident phenomena in these cases. He referred to the importance of operating early in cases of appendicitis, as Mr. Carson had done, but deplored the fact that surgeons rarely had the opportunity.

MR. J. HUTCHINSON, jun., was in doubt as to the relation of worms to appendicitis, though he had published a similar case some years ago. Their rarity was noteworthy in view of the frequency of the disease.

DR. BROOK, of Lincoln, agreed with the President as to the desirability of early operation in appendicitis.

MR. CARSON, in reply, pointed out the high mortality in the first attack of appendicitis, which was a strong argument for operation in such cases.

MR. J. D. MALCOLM related the case of
AN APPENDIX ABSCESS, WITH SEVERE HÆMORRHAGES.
The patient was a woman, *æt.* 36. A foul appendix abscess was evacuated and drained on the ninth day of the illness. On the third and sixth days after the operation there were severe hæmorrhages from the abscess cavity, the second producing unconsciousness from collapse. The wound was opened up and much clot was removed, but no fresh bleeding occurred, and the appendix was not found. The cavity was packed with gauze and healed soundly by granulation. Instances of hæmorrhage from the bowel, associated with appendicitis, and three cases resembling the one related were referred to. The complication was attributed to a sloughing action induced by micro-organisms developed in the bowel, and was compared to the secondary hæmorrhage of the days before antiseptics were introduced.

The PRESIDENT related a case in which continuous oozing occurred for fourteen days, starting on the fifth day after operation; it was not an abscess case. It was curious how rare the secondary hæmorrhage was in appendicitis.

MR. W. G. SPENCER said that possibly this rareness might be explained by the process being due to a special organism, the streptococcus hæmorrhagicus of Klein, in the existence of which he still believed. He referred to two cases of hæmorrhagic cellulitis he had seen.

MR. RAYMOND JOHNSON had seen an alarming hæmorrhage in a similar case in a boy, *æt.* 17. The

external iliac artery had been ulcerated, and had to be tied. Recovery ensued.

Mr. CHARTER SYMONDS had seen deaths from this accident many years ago. He asked whether packing or a tube had been used in Mr. Malcolm's case.

Mr. J. HUTCHINSON, jun., referred to a series of cases, published in the *Bull. de la Soc. Anat.*, in which the accident had occurred before operation. Many of the cases proved fatal. He had seen only one case after operation, it was on the ninth day. Some of the cases might be due to the slipping of the ligature on the meso-appendix. He disagreed with Mr. Symonds as to the desirability of using gauze to drain appendix abscesses.

Mr. F. C. WALLIS was strongly in favour of the use of gauze, especially a strongly antiseptic one, as iodoform.

Mr. MALCOLM said that in his case he had inserted two tubes, a large one and a small one, with no gauze.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING HELD FRIDAY, FEBRUARY 9TH, 1906.

The President, F. C. MARTLEY, M.D., in the Chair.

DEATH-RATES OF THE UNITED KINGDOM.

THE PRESIDENT delivered an address on the death-rates of the United Kingdom, explaining how the crude death-rate had to be corrected for age and sex distribution. For every 100 deaths that occurred in the United Kingdom as a whole, in Ireland amongst males, only 92.6 took place, and in England and Scotland, 100.9 and 101.7 respectively; while in the case of females the corresponding figures were 107.1, 98.7, and 102.5, thus showing how the male and female death-rate of Ireland differed so widely not only from the rates of the other kingdoms, but also from each other. In the same way the male death-rates for the different counties of Leinster were compared with those of the divisions of England, and it was found that the South Midland division had a better index of morbidity than the lowest of the Leinster counties; but what was still more noticeable was that the figure for Dublin reached the enormous height of 172.8, while in London it was only 110.7.

COMPULSORY RE-VACCINATION.

Sir JOHN W. MOORE read a paper entitled "Compulsory Re-vaccination: the Solution of Vexed Questions Relating to Small-pox," in which he drew attention to the difficulties which beset sanitary authorities who wished to make provision for the treatment of small-pox arising in their districts, and referred to legal cases—one in England and one in Ireland—where application had been made before a judge to grant an injunction restraining the sanitary authority from erecting such hospitals on the ground that they were likely to spread small-pox by aerial convection. In the English case the judge had refused—owing to contradictory expert evidence—to give a judgment, while in the Irish case the injunction had been granted as regards small-pox, but this judgment was afterwards reversed by the High Court on appeal. The author then discussed the question as to whether the infection of small-pox was carried through the air, and expressed his belief that it was. He then went on to show that efficient vaccination and re-vaccination were the real solution of this question, and pointed out that in the experience of Germany, where they had compulsory vaccination and re-vaccination, the number of persons susceptible to the poison of small-pox was so small that there were practically no special hospitals for the treatment of that disease, and he therefore held that if vaccination and re-vaccination were made compulsory in the United Kingdom we should have no need for special small-pox hospitals.

The PRESIDENT did not think anybody who studied the question from a scientific standpoint could possibly

have any doubt as to the efficacy of vaccination in the prevention of small-pox, and further expressed himself as agreeing entirely with the opinions held by Sir John Moore.

Dr. DELAHOYDE held that it would be very difficult to enforce compulsory vaccination and re-vaccination in these countries, though he thought it would be easier to have such laws carried out in Ireland than in England and Scotland, as the people of Ireland were more inclined to take the advice of medical men on such subjects, and he further said that previous to attempting to obtain legislation we ought to endeavour to educate the public.

Dr. T. P. KIRKPATRICK said that it was, in his opinion, a matter of complete indifference how small-pox was disseminated, because if the community were protected by vaccination and re-vaccination the disease could not spread.

Dr. H. U. BYRNE spoke as a public vaccinator, and, while completely agreeing with the paper, he instanced the difficulty he had experienced in getting the working-men to consent to be re-vaccinated, though they were quite willing that their families should be done. This difficulty was caused by their natural objection to be unable to go to work. He further held that there was no real objection on the part of the public in Ireland to vaccination, but went on to express his doubts as to whether the number and depth of the scars of primary vaccination were any guide as to the amount of protection enjoyed by the person.

Sir JOHN MOORE then shortly replied, and expressed the opinion that it would not be wise at present to advocate the bringing in of a Bill in favour of compulsory re-vaccination, although no opportunity should be lost of impressing on the public the value of re-vaccination as a preventive of small-pox, and the necessity for it at or about the age of twelve years.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, FEBRUARY 15TH, 1906.

The President, FRANK T. PAUL, F.R.C.S., in the Chair.

GANGRENE OF THE TOES FOLLOWING LIGATION OF THE POPLITEAL ARTERY FOR WOUND OF THE ANTERIOR AND POSTERIOR TIBIAL ARTERIES.

Mr. G. P. NEWBOLT read notes of a case of stab wound of the anterior and posterior tibial arteries and posterior tibial veins at the lower end of the popliteal space. It was necessary to ligature the lower end of the popliteal artery, and also the ends of the wounded arteries and veins. Gangrene of the toes ensued, the line of demarcation forming at the metatarso-phalangeal joints. The patient was likely to have a useful foot.

Mr. R. W. MURRAY said that a case had been recorded, in which end-to-end anastomosis of a divided popliteal artery had been successfully performed, and thought that in the case Mr. Newbolt had related anastomosis of the divided tibial vessels might with advantage have been tried.

The PRESIDENT referred to two cases bearing on Mr. Newbolt's remarks. One, a case of popliteal aneurismal varix due to gunshot wound, in which he had ligatured the artery above and below the orifice; the other, a diffuse popliteal aneurism in which he had turned out the clots and tied the artery above and below the sac. In the former case the patient just escaped gangrene; in the latter gangrene occurred, and he had to amputate the limb.

PULMONARY TUBERCULOSIS—KOCH'S NEW TUBERCULIN AND THE OPSONIC INDEX.

Dr. R. J. M. BUCHANAN read a note on a case of pulmonary tuberculosis which had been treated for some months with excellent results in a sanatorium. During a relapse, at a later period, inoculations with Koch's new tuberculin were commenced by Dr. R. Walters, and had been continued by Dr. Buchanan

since, the opsonic index being used as a guide. It was interesting to note that under relatively large doses, above 1-500 mg. the index rose, but on reverting to the smaller doses of 1-1000 mg. it had gradually fallen to below 0.8. No pyrexial reaction followed the inoculations, but with the larger doses the patient for two or three days had slight dyspnoea and lassitude. The local and general result had proved most encouraging, cough and expectoration having disappeared, as had also enlarged glands from both axillæ.

Dr. T. R. BRADSHAW said the report of the case was of especial interest because most of the successful cases hitherto published were those of external tuberculosis, probably because in them the evidence of recovery was more easily demonstrated. He had seen the cases successfully treated by Professor A. E. Wright, and they were most striking and convincing. In cases where auto-infection was taking place there was generally a variable opsonic index, due to the fact that the patient was receiving irregular doses of toxin, with the production of a negative phase, followed by more or less temporary immunity.

Dr. Wm. Carter, Dr. Grace Calvert, and Dr. J. Hill Abram also joined in the discussion.

A CASE OF PELLAGRA OCCURRING IN ENGLAND.

Dr. A. CASSELS BROWN read notes of a case of pellagra occurring in England. The symptoms having raised a suspicion as to the true nature of the disease, it was found that the patient, a young girl, had been in the habit of eating some of the maize with which she fed the fowls, and also that some of the fowls had died from the poor quality of the maize provided.

ACUTE NEPHRITIS AND ITS TREATMENT.

Dr. A. GORDON GULLAN read a paper on "Acute Nephritis (Morbus Brightii) and its Treatment," based on observations made on 42 cases of that disease. Among the predisposing causes Dr. Gullan placed a "previous attack," of which there was a distinct history in four of his cases; acute rheumatism was one of the rare exciting causes, and was illustrated by a typical example, but cold and wet, and scarlatina, were the common causes. He considered that polyuria and a moist skin were favourable signs, and noted that in some instances a fall of blood pressure, as shown by the sphygmometer occurred when the albuminuria was disappearing. Œdema was present in all the cases, but in one with very marked evidence of the disease there was no albumin in the very scanty urine for four days. The modes of termination, recurrences and relapses were described, and also a sub-acute nephritis which occurred in persons who had already suffered from the acute affection. Dr. Gullan advocated a strict milk diet, and strongly deprecated the use of solid or nitrogenous foods, and gave several examples to show that they were the frequent cause of aggravation and prolongation of the complaint. Free purgation by means of hydrogogues, free diaphoresis and counter-irritation over the loins were recommended. He considered digitalis and stimulating diuretics should never be used except in cases with complications such as cardiac failure. The treatment of uræmia should be most vigorous; bleeding followed by the intravenous injection of a saline solution, together with the judicious administration of pilocarpine was advocated. Dr. Gullan had also found chloroform inhalations useful in certain cases of uræmic asthma and convulsions.

Dr. Wm. CARTER, while agreeing generally with Dr. Gullan, differed from him on the following points:—He thought that pilocarpine should never be injected in uræmic coma, owing to the abundant bronchial secretion it produced; secondly, he objected to the total exclusion of morphine—where the complex of retained urinary poisons produced dilatation of the pupils instead of contraction, as well as other symptoms similar to those caused by atropine. A hypodermic injection of $\frac{1}{4}$ gr. brought natural sleep, followed by cessation of convulsions; thirdly, oxygen might often be freely administered with great advantage—the dissolved oxygen of the blood serum might be increased five-fold by this method, and he was sure that he had

seen lives saved by it, owing probably to the oxidation of toxic products to the condition of harmless urea, as the urea was certainly increased after giving it; lastly, in cases of total suppression, a hypodermic injection of 2 or 3 grs. of caffeine dissolved in a solution of salicylate of sodium would be followed by the passage of a little bloody urine and then copious diuresis. One drachm of salicylate solution will dissolve 20 grs. of caffeine.

Dr. T. R. BRADSHAW said that a moderate rise of blood pressure in the course of acute Bright's disease was of good augury, the worst cases being those in which the pressure remained permanently low.

Dr. A. STOOKES regretted that Dr. Gullan had not discussed the question of treatment of severe uræmia associated with pregnancy. No mention had been made of certain methods of treatment which were at present interesting to obstetricians, e.g., large doses of morphia, thyroid extract, lavage of the stomach, or injection of normal saline solution into the cellular tissue or veins. Dr. Stookes wished to draw attention to a remarkable series of cases lately published by the Rotunda Hospital, where 71 cases of eclampsia were treated with a mortality of 1.69 per cent.

Dr. J. LLOYD ROBERTS called attention to the fact that nephritis occasionally occurred in children, as a complication of mumps—a fact which made the routine examination of the urine in this complaint desirable. He also referred to the usefulness of morphia in certain cases of uræmic dyspnoea.

Sir James Barr, Dr. E. T. Davies, and Dr. Buchanan also spoke.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD, FEB. 16TH, 1906
Mr. R. FAVELL, the President, in the Chair.

PUERPERAL SEPSIS WITH THROMBOSIS OF THE OVARIAN VEINS—DOUBLE LIGATURE—RECOVERY.

Mr. A. CUFF (Sheffield) read a communication on the treatment of septic thrombosis of the pelvic veins by means of ligature as advised by Bumm in 1894, and showed the charts of some of the few cases in which this measure has been employed. He recorded a case of sub-acute puerperal pyæmia in a woman, æt. 30, who began to have rigors two days after she had been delivered by a midwife. Serum was first injected for several days, but the rigors continued, and the case ultimately came under Mr. Cuff's care. He found a doughy swelling in the right iliac region, and after observing the case for a week, during which the patient lost ground, he opened the abdomen and found the mass to be composed of thrombosed veins and œdematous connective tissue. The tube and ovary were not affected. The mass was ligatured within and without, and the left ovarian vein, which contained clot throughout its length, was ligatured just below the kidney. The rigors ceased at once, and the patient made a rapid and complete recovery.

FIBRO-MYOMATA WITH VARIOUS COMPLICATIONS.

Drs. BRIGGS and WILLETT (Liverpool) showed two fibroid uteri removed, one by vaginal, and one by abdominal hysterectomy. The cavity of the uterus in each case contained a polypus more or less tongue-shaped, and of considerable size. On microscopic examination one of these polypi proved to be a large round-celled sarcoma of the endometrium, while the other was an adeno-carcinoma of the endometrium. In the latter case the ovary contained secondary carcinomatous masses.

Dr. DONALD (Manchester) described a patient with multiple fibroids, one of which necrosed and consequently became firmly adherent to the abdominal wall and to bowel. This caused intestinal obstruction, which was with difficulty overcome after lasting for a week. The uterus and myomata were subsequently removed with success. He also showed a uterus with multiple fibroids—one of which occupied the uterine

cavity. This had caused bleeding only at the advanced age of sixty-four years, which suggested the existence of malignant disease of the body.

Dr. LEA (Manchester) showed a fibro-myomatous uterus, the size of a football, which caused no symptoms whatever until pregnancy began. It then caused intense pain and difficulty in micturition and defecation, and was therefore removed at the sixth week of gestation. In a second case the fibroid uterus was removed near the seventh month of pregnancy because it was causing constant pain, for the relief of which morphia was required, together with intense bladder trouble and pressure on the bowel. He had been forced to operate to relieve the symptoms, and not in anticipation of difficulty during parturition.

Dr. BLAIR BELL (Liverpool) showed a growth occupying the uterine wall and consisting largely of small arteries whose walls had undergone hyaline degeneration. When fresh it appeared as a grey gelatinous mass interspersed with hard white nodules, and seemed to occupy a cavity within the uterine wall. It was best named an angiomatous fibro-myoma.

Dr. BLAIR BELL also showed a tumour of the kidney which had occupied the right iliac fossa. It was the size of a foetal head, and was an example of the rare growths known as hypernephromata and developed from suprarenal "rests" within the kidney.

ECTOPIC GESTATION.

Dr. W. WALLER (Manchester) showed two specimens of ruptured tubal pregnancy removed by abdominal section at the sixth and eleventh weeks. In each case sudden abdominal pain preceded severe fainting. In the first case, marked pulsation of the uterine artery aided the diagnosis.

THERAPEUTICAL SOCIETY.

A GENERAL meeting and conversazione was held in the Apothecaries' Hall, on Tuesday, February 20th, Sir LAUDER BRUNTON, President, in the chair. Thomas Maben, F.C.S., read a paper on the

PREPARATION OF ANTI-DIPHTHERIA SERUM.

illustrated by very good limelight views, showing that the toxin of diphtheria is formed by cultivating the bacillus in alkaline beef bouillon for about seven days, and then filtered and stored in the cold. It is then tested on guinea-pigs, and afterwards injected into perfectly healthy horses, in minute doses at first, gradually increased every week, till 1,000 c.c. can be injected without injuring the animal; this dose would kill 100 unprotected horses. By this a powerful anti-toxin is developed in the blood, which protects the animals from the diphtheria toxin. This usually requires nine months' treatment, after which about a gallon of blood is taken from the jugular vein every week into glass cylinders, kept cold for four days till the serum separates, which is drawn off and filtered, and used after three weeks if the horse keeps well. If properly kept it may retain its power for two or three years, and it is most important to inject the serum into a case of diphtheria without any delay, as if it was used on the first day of the disease only one in 238 died, while if delayed to the fourth day one in nine died. As there is no danger from the serum, large doses should be used; in severe cases from 12,000 to 24,000 units are often required. In America and Germany the Government guarantees this efficiency of the serum, but in England private experts test it. Dr. Montgomery Paton states that the serum is also useful for other microbes, as the streptococcus, staphylococcus, and bacillus coli communis.

A paper on

CLOUDS AND CLIMATE.

by Dr. STUART TIDEY, of Montreux, Switzerland, showed that there a cloudless day is rarely met with after sunrise, as very shortly afterwards mists arise from evaporation, on the snowfields and glaciers, and gradually extend over the neighbouring valleys, and may form rain, but after sunset evaporation ceases, and the clouds disappear. The clouds increase more

rapidly when the air is moist than when dry, and are higher in summer and lower in winter, even down to the level of the lakes, so that in winter the summits of the mountains are often free from mists and in full sunshine, while the lower altitudes are covered with dense clouds, but in warmer weather the lower levels are free from mists while the peaks are enshrouded by them. Hence it is advisable in the autumn to reside at a low level with easy communication with higher regions, and Montreux is very favourably situated, as in warm weather it is free from clouds and damp, but in winter when it is wrapped in clouds several railways lead to higher regions, such as Sierre 1,765 feet, Seysin 4,500 feet, Caux 4,000 feet, LesAvants 3,200 feet, which are easily reached by rail from Montreux, and have good hotels and winter sports. Also Corbryer, 3,500 feet, is one of the best winter stations with good hotel accommodation, but it can only be reached by to carriages as there is no railway.

THE CENTRAL MIDWIVES BOARD.

MEETING HELD, FEB. 22ND, 1906.

The President, Dr. CHAMPNEYS, in the Chair.

At the beginning of the meeting a letter was read from Dr. Stookes, of Liverpool, as to the scope of the teaching prescribed by the Board on the subjects of (1) sanitation; (2) emergencies. The writer said grave risks were run by the varied teaching given, and by (comparatively) ignorant women using in emergencies instruments for serious operations, such as curetting the vagina, etc.

Letters were also read from Dr. Fairbairn and Dr. Hicks with regard to the defective training of a candidate at the recent examination. She had the vaguest ideas as to aseptic conditions.

The PRESIDENT said that these letters would meet with consideration when the rules were revised, and the secretary read a letter from Dr. Fothergill, on behalf of the Manchester examiners, suggesting the board should publish an official handbook for midwives to secure more uniformity of teaching.

Sir WM. SINCLAIR remarked that the Board was two years behind the times. In Germany there had already been six such manuals.

Mr. WARD COUSINS added that one of the chief difficulties of examination lay in the elementary educational condition of some of the candidates. These did not seem to have language at command to formulate their answers. Moreover, they ought, besides the midwifery course, to have lessons as trained nurses have. Very often one of the latter would be more useful than a midwife.

Sir WM. SINCLAIR answered it was clear that deficiencies existed in clinical teachers and their methods. Many on the list were not qualified to give such instruction. Such women should have had training as a fully certified nurse.

As Dr. Swayne (Bristol Centre) had also to complain of defective training, it was resolved to hold a committee of examiners and receive their suggestions.

The matter of institutions claiming exemption from Government inspection with regard to lying-in wards was again discussed, as the Clerk of the L.C.C. had written for a full definition of Rule E. 21 which deals with this, and the Stockwell Private Hospital had claimed exemption.

The PRESIDENT said the rule had been framed to avoid interference with the staff of large institutions, but the Local Government Boards were always trying for exemption, and he was glad for the L.C.C. to support the Central Board of Midwives.

Sir WM. SIMPSON remarked that it would never do to exempt small institutions and private hospitals, for these were the very places where grave moral abuses might be in vogue.

It was then agreed to send an answer confirming the L.C.C. in their action.

The Secretary's report of the February examination was presented to the Board.

Sir WM. SINCLAIR protested against the way in which it was drawn up. A mere list of successes told nothing. The prime question just now was the efficiency of teachers. A list of those who had failed and who had taught them ought also to be given. It was his impression that the failures had been under illiterate midwives. He had carefully studied returns from institutions and found women had signed certificates of more cases attended than could possibly have come under their attention.

Mr. WARD COUSINS then moved a resolution, which was passed:—"That the form of suggestions accompanying the Agenda of December 14 for the guidance of the medical advisers of the local supervising authorities, respecting the duties of inspectors appointed to exercise general superintendence, be approved and issued to the local supervising authorities." Adding that such clearer guidance as to their duties would be welcomed by all such authorities.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, February 28th, 1906.

RHINITIS IN CHILDREN.

ACUTE purulent rhinitis coincides frequently with impetigo of the face, but it can exist alone. It is subject to intermissions and has a tendency to become chronic.

The maximum of frequency of this affection is between seven to twelve years of age; it is particularly observed in lymphatic children. The inflammation may be localised to the vestibule of the nares, or it may invade the pituitary membrane. In the former, the edges of the cavities are inflamed and fissured. The interior of the nose is filled with hardened secretions. When these become detached, the mucus membrane is red, glistening, and sometimes ulcerated. The secretion continually renewed obstructs the passage of air, and the patient shows the symptoms of adenoid vegetations—mouth open, snoring at night, &c.

In the deeper form of rhinitis, the disorders are still greater; the inflammation can extend to the pharynx, and all the organs which communicate with the nose; ocular complications, keratitis, kerato-conjunctivitis, ulcer of the cornea; of the ear, otitis acute and chronic; of the skin, erysipelas, impetigo; of the pharynx, inflammation of the tonsils, adenitis, ending in vegetations; of the respiratory tract, laryngitis, bronchitis, and broncho-pneumonia.

The diagnosis of purulent rhinitis is easy, but two causes of error should be borne in mind—the presence of a foreign body in the nares and adenoid vegetations. A careful examination will eliminate those possibilities.

The treatment consists in irrigation of the nose by means of an enema syringe. Each naris should be washed out two or three times a day; a pint of solution should be used each time. The child should hold its head over a basin, and avoid speaking or swallowing, so that the liquid should not penetrate into the Eustachian tubes.

The solutions should be warm, and composed of, says Lannoyez, chlorate of potash, bi-carbonate of soda, or bichlorate of soda at 5 per cent., and afterwards antiseptic solutions might be used as phenosalyl (1—1,000), resorcin, $\frac{1}{2}$ per cent., boric acid, 3 per cent. In slight forms an ointment of boric acid (2 per cent.), resorcin (5 per cent.) or salicylic acid (1 per cent.) inserted into the nares may be sufficient. Sometimes a powder might be substituted for the ointment, either euphene or aristol mixed with equal quantities of sugar, of milk and used as snuff.

If the desired result is not obtained, a preparation of nitrate of silver may be ordered.

Nitrate of silver, 5—10 grs.

Talc powder, 6 drachms.

The general treatment consists in cod liver oil tonics and a season at Challes or Luchon.

PURULENT RHINITIS OF INFANTS.

The child can come into the world with purulent rhinitis; in such cases it is injected by the amnion which had prematurely escaped. More frequently twenty-four or forty-eight hours after birth the malady is declared, and almost always it is due to hæmorrhagic contagion during the passage of the head in the vagina. The nature of this coryza, for so long denied, is to-day proved. The fact of the co-existence sometimes observed with purulent ophthalmia and rhinitis is a sufficient demonstration.

The symptoms are here more pronounced than in the preceding form. The pus is thick, creamy, and irritating. The nares are inflamed and painful, while the nasal obstruction is considerable. The affection is very tedious and ends frequently in ozena.

Ænorrhagic coryza differs from the syphilitic form by its early appearance and by the aspect of the secretions; in syphilitic patients, the liquid secreted is sero-sanguinolent and, moreover, other manifestations of the specific disease can be observed.

The nose should be irrigated by the same solutions as in the ordinary purulent type and the following powder blown into the nose:—

Iodoform, xv;

Berzoin powder, $\frac{1}{2}$ drachm;

Boric acid, 3 drachms.

Irrigation of the nose with resorcin (1 per cent.) is very efficacious in such cases.

CEREBRO-SPINAL MENINGITIS.

Numerous are the agents tried for this dreaded affection, and amongst the most recent may be mentioned the injection of collargol into the rachis. M. Papillon reports such a case. A child, $\text{æ. } 3\frac{1}{2}$, suffered from cerebro-spinal meningitis. A first injection of one-third of a grain of collargol produced improvement, but temperature having risen to 104° a second injection of one grain of collargol was injected and the patient rapidly recovered. Another practitioner reports four cases of meningitis cured by the creation of artificial abscesses. Twenty drops of essence of turpentine were injected into the external part of the thigh. At the end of a week the abscess was ready to be incised. In one case the injection produced no inflammation, and the patient succumbed.

Intra-rachidian injections require a certain amount of practice, and consequently are not within reach, perhaps, of the ordinary practitioner; but the creation of abscesses can be done by any one, and are worth a trial.

GERMANY.

Berlin, February 24th, 1906.

At the Verein für Innere Medizin, Hr. Senator discussed

THE DIETETIC TREATMENT OF GASTRIC ULCER.

In his remarks he would restrict himself to the question: How is the recent bleeding ulcer of the stomach to be treated? It was known that in such cases it had been recommended to exclude food by the mouth absolutely for a time, to feed by the rectum and then cautiously return to stomach feeding again, and this method of treatment had found many adherents. More recently Lenhartz had opposed this on the ground that it tended to exhaust the patient's strength, and thereby retard the healing of the ulcer. He ordered from the first a very concentrated albuminous diet, beaten-up eggs, and from the sixth day scraped meat. In this way he was said to have obtained quicker results. Since then experiences recorded from various quarters had seemed to confirm this. Kleinberger, however (against his own will), from experiments had confirmed the views of Zienissen-Leube as to the

advisability of abstention from stomach feeding, or under feeding. He found that this method ensured a lowered blood pressure, concentration of blood, increase in hæmoglobin, in fact exactly the condition met with during the fasting state.

The speaker had proposed a middle way and had tried it in many cases. He had given small quantities of albumen, gelatine, fat and sugar. He had used gelatine for thirty years in his fever diet on account of its great nutritive value, and its easy digestibility. But gelatine had also great power of coagulating blood and of arresting hæmorrhage, its local effect being very marked, and its remoter action after injection into vessels being far less. Fat and sugar, independent of their great nutrient value, were, the latter, a relief for acids, and, the former, a soother of irritation and calmative. He gave the gelatine in the form of a decoct. gelatine alb. pures 15 to 20 grm., with 50 gm. Eleosæch, citr., the dose to be taken in the 24 hours. With this as albumen he gave a small quantity of cream with a little fat and sugar, the fat in the form of butter, which was best taken in the form of small frozen pellets (30 grm. pro die). This food gave the patient twice as many calories in the day as Lenhartz's—900 to 1,000. It contained far less albumen than Lenhartz's, being almost replaced by gelatine. Later on milk, beaten up eggs, scraped meat, etc. Occasionally he had seen hæmorrhage take place immediately after taking the gelatine decoction. This diet could be modified according to the patient's taste. Chicken jelly, calves' foot jelly could be given with variations. Fat was best given as butter, but also in the form of almond oil emulsion. This diet was rational, healing, and nourishing.

At the meeting of the 5th inst., Hr. Löwenstein communicated a note on

IMMUNITY.

He said that whilst in most cases of acute infectious disease a condition of immunity follows the cessation of the disease this was not so in the case of chronic infectious diseases. In this respect they resembled the two acute diseases that gave rise to no immunity, viz., gonorrhœa and erysipelas. These two were also alike in that the disease in both remained local and did not attack the organism as a whole. The speaker expressed his belief that this property of merely local action was the cause of the absence of immunity when the disease subsided. To produce the immunity, therefore, it was necessary that there should be a general saturation of the organism with the disease, and in the case of the chronic infectious diseases this should be brought about by introducing the disease product into other organs. For example, in carcinoma, carcinoma mass should be given internally.

At the Society of Charité Physicians, Hr. Orth spoke on

BONE CALLUS.

In a man æt. 84 who had had an impacted fracture between the neck and the strap of the femur, and who died fourteen days after, it was found that the greater part of the callus was formed of osteoid tissue, and with this a large amount of bone substance. The causes of callus luxurians were of an individual nature, they were neither great dislocation nor much movement of the fractured parts. With regard to the origin of "parosteal" callus, a connection with the periosteum was possible. On the other hand, the assumption of a heterogenous bony formation was allowable. Such heterogenous bony growth, when it did not spring from the periosteum, was the result of metaplasia. Connective tissue, cartilage and bone could pass into one another. One had to distinguish between cell and tissue metaplasia. In the first the connective tissue cells showed an osteoblastic function, in the latter the connective tissue fibres became bony basic substances and the connective tissue cells bone cells. There were no typical osteoblasts in the case under notice; there was no periosteal origin, but a development from connective and fatty tissues. Besides this the preparation showed calcification, but not of the

newest bony masses. Wherever there was lime there was also a positive iron reaction, as was also shown in normal osteous formations. As regarded the occurrence of cartilage tissue in callus, this was found in aseptic fractures, as was shown by animal experiments, in the adult as well as in the child.

Hr. Beitzre communicated a note on

DIFFERENTIATION OF STREPTOCOCCI BY CULTIVATION ON A BLOOD NUTRIENT SOIL.

Several of the streptococci of the streptococcus longus and the streptococcus meteor changed the character after lengthened cultivation, partly after passage through animals, one after inadvertent passage through the speaker himself, when cultivated on blood, the streptococcus longus becoming converted into the s-meteor and vice versa. E. Fraenkel's criterion also failed (characteristic growth on litmus, milk, sugar agar). S. mucosus was only distinguishable from the pneumococcus on a solid soil by its mucoid growth, but even this distinction was lost by prolonged cultivation. The speaker therefore classed the streptococcus mucosus as a pneumococcus.

AUSTRIA.

Vienna, Feb. 24th, 1906.

At the Gesellschaft Kirchmayr presented a young woman, æt. 26, on whom he had operated for abscess of the liver. The patient took ill with typhoid in September, but in November commenced to show signs of irregular temperature with increase of the spleen.

This organ was probed twice and pus obtained both times. The spleen was next resected by carrying an incision across between the tenth and eleventh ribs. On reaching the spleen an abscess about the size of a hen's egg was met with, which when opened was found to be mucoid pus full of typhoid bacilli.

CATGUT STERILISATION.

"Frank recorded his success in sterilising catgut by keeping it two days in a concentrated solution of Formalin and then boiling for twenty-five minutes in water; finally placing it in alcohol for immediate use.

Shnitzler said he had tried that method for some time, but now prefers iodine catgut as being better sterilised and also a disinfectant when left in the tissues.

SUBLINGUAL GROWTHS.

Goldreich showed a child with a swelling about the size of a marble in the frenulum linguæ, hard and of a fungoid appearance; not painful on pressure, but ulcerated on the surface. The history is most peculiar; for seven weeks past it has suffered from pertussis, but according to the mother's convictions it suffered from a spasmodic cough shortly after birth. The real cough commenced about seven weeks ago, occurring every quarter or half-hour. The mother affirms that no swelling was present when the whooping commenced. The question arises, What is the cause? Is it due to the incisor teeth causing first ulceration with subsequent infiltration? He was of opinion that the pathological origin was a mechanical irritation resulting in a papilloma or granuloma.

He had tried the usual absorbing and assuaging methods without success and now proposed to extract the incisors.

Swoboda recorded several such cases coming under his notice which went away of their own accord. He thought extracting the incisors too heroic at the present time. Kassowitz also thought such treatment unnecessary.

PURPURA AFTER SCARLATINA.

Schick showed a specimen taken from a girl, æt. 5½, who commenced with fever and vomiting on December 16th. A few days later the throat became affected, while a typical scarlet rash appeared on the skin and which disappeared after three more days.

On the sixteenth day of the illness points like pin heads began to bleed on the cutaneous surface of the right arm, hand, mucous membrane of the lips and throat. The deposit on the membrane of the throat and fauces was black with intense fætor exore from the

resulting gangrene. The lymphatics were about the size of hazel nuts and hard. On the seventeenth the urine became hæmorrhagic, but no albumin beyond that calculated in the blood.

The patient died on the twenty-first day of the illness from exhaustion. In the *post mortem* the entire surface of the fauces, tongue, tonsils, and larynx were covered with a reddish stinking fluid. Below the epiglottis the same conditions existed. The origin seemed to be due to a hæmorrhagic diathesis.

CONGENITAL STENOSIS OF INTESTINE.

Preteitner related an umbilical hernia in a new-born child, where laparotomy was performed, and the ileum found connected with the amniotic sac. The cord leading into the bowel was two fingers thick and contained meconium. At the attachment to the small bowel the lumen of the latter was obliterated. The stenosis was removed but the child died.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE FACTORS WHICH MAKE FOR SUCCESS IN LIFE.—Sir Frederick Treves gave his Rectorial Address to the Aberdeen Students in the Mitchell Hall, on the 22nd inst. The speech was listened to with close attention and interest throughout and the whole proceedings were orderly in the extreme. After thanking the undergraduates for choosing him as their Lord Rector, Sir Frederick took as the subject of his remarks, the factors which make for success in life—particularly in the medical career. The fascination of medicine was the heroic character of the calling, and the true spirit of the profession was not illustrated by the brilliant surgeon who holds the operating theatre spellbound, not by the learned teacher who can grasp the attention of a crowded audience, but by the solitary man in a gig pushing over a bleak moor in wind and rain to help another poorer than himself. Modern medicine finds its romance in discovery; the shadowy Argo or the weather-beaten brig the "Golden Hind" seeking a new world are no more romantic than the figure of Laennec glancing with rapture at the almost invisible speck on the needle's point—the miliary tubercle discovered after months of monotonous toil. Few detective stories surpass the tale of the tracking down of the miscreant malaria after many years of astute watchfulness. In enumerating the factors which make for success, money, influence and social position, and above all, genius, are supposed to be of importance. In Sir Frederick's estimation, ample or moderate means at the outset of a career was a positive drawback; no influence would make a worthless man worthy, nor the incompetent capable. As for luck, the man who is content to wait for a stroke of good fortune will probably wait until he has a stroke of paralysis. Most specious of all is the contention that success in a profession needs genius. Genius in its crude or natural state is not wanted in medicine, nor has it been a marked attribute of those who have attained the highest position in that calling. Genius in a physician would be apt to give us flippancy, instantaneous diagnosis, the instinctive detection of disease, and other astounding phenomena which one attributes to the charlatan. In like manner brilliancy in a surgeon is a quality from which he may well pray to be saved. The synthetically composed genius is safer and more reliable than the congenital genius—into the making of the synthetic genius enter the capacity for hard work, for patient observation and experiment, for persistent reasoning; these have no supernatural origin, but are within the reach of any mortal. The important factors in success are health, serviceable knowledge, sympathy, and honesty; industry is pre-supposed. Sound health means more than capacity for work; it means an equable mind, a prompt judgment, and a disregard for worry. Highly cultivated special knowledge must be supplemented by

an intimate knowledge of the anatomy and physiology of man as a social being—a subject slow and hard to learn. In the mathematics of life no factor is more important than the personal equation. The successful physician is a finished student of men. From the doctor the public demand unwavering dogmatism, and will have no talk of uncertainties. Now that medicine approaches an exact science there is no need for invention to gratify the demands of a sick man—it is not even necessary to babble about his "constitution" or his "tone," any more than to tell him now that a malady is due to a "humour" as the mediæval physician must have said to his patient in the days when truth was as scarce as the supply of radium. Sympathy counts for much—not a mere profession of kindly platitudes, but such a frame of mind as is attained by anyone who can project himself into another's place. The physician who is able to conceive of a disease not only as his art would show it to him, but as it appears to the view of his patient, has grasped the foundation of therapeutics. The blunt, outspoken truth may, from want of tact and insight, be far from commendable. Finally, honesty, of which there is one degree—it either is, or it is not—is not only the best, but the only policy. That "Nothing succeeds like success" is no article of faith in a true *religio medici*. Riches is the least of its gains, but by the earning of gratitude the humblest practitioner lays hold of wealth beyond the dreams of avarice.

BELFAST.

OVERCROWDING AT THE DISTRICT ASYLUM.—A special meeting of the Asylum Committee was held last week to consider the question of overcrowding at the old asylum at Grosvenor Street, Belfast, and the feasibility of transferring all patients there and at the Ballymena Workhouse (where a number are at present housed) to the new asylum at Purdysburn. Year after year the Government inspectors have made strong remarks on the very inadequate accommodation at the old asylum, and the Committee have now to face a scheme for the removal of all patients to Purdysburn, whither the excess were removed some years ago, and housed in four new villas. The Purdysburn estate comprises 372 acres in a splendid situation within easy reach of the city, and there would be many advantages in having all the insane together under one central administration, instead of scattered as at present. But a complete set of villas, with the necessary water supply and administrative block would cost about £100,000, a sum not to be lightly disposed of. The committee practically agreed that some such step was unavoidable, and appointed a sub-committee to inquire into the matter and formulate a scheme.

DOWN DISTRICT ASYLUM: INCREASE OF SALARY.—The Committee of Management of the Down Asylum last week decided to increase the salary attached to the office of junior assistant medical officer from its present figure of £100 to £130, rising by annual increments of £10 to £150 a year.

BELFAST MATERNITY HOSPITAL.—The one hundred and twelfth annual meeting of this charity was held last week, when the medical report was read by Dr. Osborne. It stated that 326 patients were treated in hospital last year, 306 children were born alive, and 21 still-born. There were four maternal deaths, one from tuberculosis, one from pleurisy, one from pneumonia, and one from eclampsia, the last having been admitted in a moribund state. 312 patients were attended in their own homes.

THE late Mr. Thomas Moreton, M.R.C.S., of Hartford, Northwich, Cheshire, surgeon, left estate valued at £54,097. The testator left £100 each to the R.S.P.C.A. and N.S.P.C.C., £200 to his coachman, £50 to his servant Albert Dutton, £10 to his servant Ann Bowyer, and a life annuity of £20 16s. to Mary Cotterill, late caretaker of his surgery at Northwich.

LETTERS TO THE EDITOR.

MERCURIAL INJECTIONS IN THE TREATMENT OF SYPHILIS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the synopsis of the discussion at the Medical Congress held in Paris, 1905, published in your issue of the 7th inst., would you allow me to state that I most cordially agree with Dr. Hallopeau when he says: "Mercurial injections are not to be recommended in general, and should only be had recourse to in severe cases." I suppose by severe cases he means cases presenting severe symptoms, especially tabetic symptoms, and in these the intra-muscular injections would undoubtedly be of use in helping to remove the symptoms, but here, Sir, to my mind comes the great point: there seems to be too much inclination amongst medical men in treating syphilis only to consider the symptoms present at the time, and to lose sight of the constitutional disease which it is their duty to eradicate from the patient's system. We all know how strictly, as a rule, the patients themselves adhere to treatment as long as any symptoms persist, and how consistently they neglect to continue a remedy which necessitates the slightest trouble when all visible signs of the disease have disappeared. In my opinion, therefore, intra-muscular injections should be reserved for the treatment of any particularly obstinate symptoms such as those enumerated in 1904 by my old teacher, Professor Alfred Fournier, but I do not think they will ever come into vogue for the eradication of syphilis from the system; to do this requires the administration of mercury for at least two, some say three years. Now, where is the patient who will consent to undergo a bi-weekly injection into the muscle substance of his gluteal region or of his spinal furrow during two or three years, or even during one year, which last is, I believe, the limit of time fixed in this method of treatment? To go further, let us suppose a man has submitted to the expense and delectation of a bi-weekly spearing with the syringe for one year, would a medical man feel himself justified in then giving his patient permission to marry on the assumption that the poison of the disease had been eliminated by the treatment? Personally, I should not. Apart from the unpleasantness of these injections, there is the question of expense, which to many would be a serious consideration; the intra-muscular treatment, if continued for any length of time, could only be the appanage of the rich, and if carried out for a short, and therefore a quite useless, period the appanage of the very poor, who are supposed to be the class receiving relief at our hospitals. Again, this treatment, however carefully carried out, must always present some risks, as pointed out by Dr. Hallopeau. To sum up, it is the duty of every medical man to eradicate the poison of syphilis from the patient's system and this is only accomplished by a mercurial course lasting from two to three years; therefore the internal treatment is, in my opinion, the proper one as well as the most easy, and for this reason the most likely to be rigorously continued by the patient at the time when symptoms have temporarily disappeared; intra-muscular injections, on account of their power of producing at once greater mercurial activity, may be of great use during a short period in combating any individual severe symptom. It is essential to watch the case carefully at the beginning of the internal treatment in order to find out the form or combination in which the mercury can be administered to the patient under notice without producing any results but those desired; were this invariably done, those unpleasant effects sometimes brought about by the drug when administered by the mouth, which are invariably mentioned in disparagement of the internal treatment, would cease to exist.—I am, Sir, yours truly,

H. DE MERIC.

13, Nottingham Terrace, Regent's Park, N.W.
Feb. 22nd, 1906.

SPECIAL ARTICLE.

THE CAUSATION OF INSANITY.

ONE of the features of Dr. Easterbrook's annual report of the Ayr District Asylum is the careful investigation which is made as to the causation of the insanity of the patients, and as there are on the Asylum Register about 500 patients, with 151 admissions during the year, the numbers dealt with are sufficiently large to be of statistical value. Dr. Easterbrook has been able to trace the family history of 120 direct admissions, with the result that the following hereditary diseases were found to be present:—Insanity in 26·8 per cent., neurosis in 14·1 per cent., tuberculosis in 14·1 per cent., paralysis (chiefly apoplexy) in 12·5 per cent., alcoholism in 9·1 per cent., heart disease and cancer in 6·6 per cent., chronic rheumatism in 5·8 per cent. From these facts a table has been prepared showing the degree of affinity to the patient of the relatives affected; as might be expected, the morbid heredity shows itself most frequently in affinity of the first and second degree, namely, parents, and brothers and sisters, and much less often in the third degree (grand-parents) or fourth degree (uncles and aunts). Dr. Easterbrook believes that the neuro-insane constitution was the most important factor in producing insanity among his patients, being present in nearly 58 per cent. of cases. The neurotic diathesis alone accounted for insanity in 29 patients; in the rest it was assisted by emotional strain and the physiological crises of life. The question of the relation of alcoholism to mental disease is always of interest, and we note that in the experience of Ayr Asylum it is a less potent factor than is held by some. Alcoholic excess was manifested by 33 patients, in 14 of whom it was symptomatic of insanity, and in 19 the essential causal factor. These figures show a slight increase over the preceding year, which may be co-related with the signs of revival of trade. Dr. Easterbrook divides cases of alcoholic insanity into three groups:—(1) The true *dipsomaniac*, in whom the disease consists, not in the effects produced by constant excessive indulgence in alcohol, but in a periodic intense craving for the mental state induced by alcohol, morphia, or similar drugs, which, acting on the higher functions of the brain, excite or calm the mental functions. The dipsomaniac seldom finds his way into an asylum, may occasionally be induced to go into an inebriate retreat, but usually is screened by relatives, who, knowing his weakness, if wise do all in their power to help him to fight against it. (2) The careless or ignorant *drinker* who constantly takes more than is good for him, but manages to keep more or less respectable until some day a breakdown occurs. This type forms a large proportion of the alcoholic insanity in asylums. They often, though not always, recover, and seldom return—one lesson, the *dernier ressort*, has been enough. (3) The chronic inebriate or alcoholic *deteriorate*, who as the result of prolonged habits of vicious indulgence—he may have begun as a dipsomaniac or careless drinker—has spent his money, mind and morals in drink, and is left as a derelict for the asylum, beyond redemption. To all these—the dipsomaniac, the drinker, and the deteriorate—the only safeguard is total abstinence.

As to the mental and bodily condition of the patients admitted, 10 were in the first class of mental reduction (60 in the second class, *i.e.*, showing marked depression, exaltation, or confusion, or hallucinations, delusions, stupor, etc; and 56 in the third class, *i.e.*, more marked degrees of the above, or the presence of morbid obsession, inhibition or moral sense, or dementia, etc. Grouping mental and physical characters together, 5 were bodily fair and mentally mild; 53 bodily poor, or mentally moderate; 68 bodily weak or mentally severe. The recovery rate for the year, 42·06 per cent. of the direct admission, is gratifyingly high. The death rate was 13·62, the most frequent causes of death (*p.m. exam.*) being tubercle, heart disease, general paralysis, and pneumonia. The death rate is

higher than the average, but the mean age at death was also high, and it has happened that during the year a number of debilitated old women have been carried off by intercurrent maladies.

From the administrative part of the report, we find that the New Hospital is approaching completion and will raise the available accommodation from 500 to 650 patients. Electric light has been installed, and a fire alarm system of electric bells introduced. The reports of the Commissioners in Lunacy are couched in complimentary terms.

REVIEWS OF BOOKS.

KRAEPELIN'S CLINICAL PSYCHIATRY. (a)

TEXT-books on mental diseases are apt to fall into two classes—the ponderous or recondite, fit only for the expert, and the sprightly, or unsatisfying, which the student and general practitioner have to put up with. The volume before us hits a very happy mean between the two. Let us say at once that no reader, expert or student, can fail to be influenced by the charm and sagacity of the author, and if he gain nothing more from its perusal than a lively sense of the attractiveness of clinical psychiatry, he will be refreshed on the one hand and stimulated on the other. But valuable, highly valuable, as is this attribute, we should be doing the author an injustice if we did not add that it is instructive in a rare degree. The expert will find in it the fruit of a ripe clinician which will taste fresh and luscious after some of the Dead Sea fruit which rasps his palate from time to time; let him take it to his fireside on an evening, and he will soon forget the asperities of the day. To the lay, or non-expert, it will be a very Hans Andersen for fascination; more interesting than a novel and more filling than a text-book. The author has chosen the clinical lecture form in which to express his thoughts, and in a few sure strokes he succeeds in delineating a vivid picture of the leading features of each of the various types and phases of mental disease in such a way as to convey a clear-cut and lasting impression. We have come across no book which would better serve as an introduction to the systematic study of psychiatry, and we can strongly advise students who are attending asylum demonstrations to make it their hand-book during their course. If they do so, and compare its teaching with what they see in the wards, they will carry with them into practice a personal acquaintance with the clinical manifestations of insanity and their diagnostic significance which will stand them in good stead for the rest of their lives. Although this volume is not primarily a systematic treatise, the lectures it contains practically cover the field of mental disease, and an attempt to bring them into orderly relation is made by adding a scheme of classification. Of this it may be said that it is about as satisfactory or unsatisfactory as any other scheme of the kind. As long as symptomatology and clinical history are relied upon to furnish the criteria for one part of a classification, and toxic insanities are relegated to groups in which etiology determines the relationship for the other, it is hopeless to expect anything like scientific precision or absolute consistency. That this should be so merely indicates the confusion of thought that exists everywhere with regard to the interdependence of the several departures from the normal which are termed mental diseases, and which would appear only capable of reconciliation by the adoption of Sankey's generalisation that insanity always follows a definite course and passes through the various stages of dissolution—melancholia, mania, dementia, and amentia—however much any individual stage of the

process may be abbreviated or thrust into prominence. Till this theory, or some better one, is adopted generally by alienists, we shall continue to have these classifications which at best can only be stop-gaps in the absence of fuller light. And Dr. Kraepelin's is as good as any for the purpose. The translator is heartily to be congratulated on the skill he has shown in doing the book into English. He has almost completely eliminated the heavy Teutonic rumble which grates so uncomfortably on the Anglo-Saxon ear in all German books and nearly all English translations of them. He has given us a bright, crisp, vivacious, and idiomatic rendering of the author's text, which makes the reading of it a pleasure in itself. In a word, he has "Englished" it.

KAYSER ON DISEASES OF THE LARYNX, NOSE AND EAR. (a)

THE attention of the author, as expressed in his paper, is to record for future reference his lectures—not to supplant those lectures, for, as he justly points out, nothing can actually take the place of clinical observation—and also he lays stress upon the inclusion in one volume of the three special branches of surgery, throat, nose, and ear, which have been divided up too much, and which, as he points out, have so much in common that it is hard to separate them. After some general remarks with regard to the use of reflected light, &c., he passes to the consideration of laryngeal examination, and discusses the various methods of direct and indirect laryngoscopy and also bronchoscopy.

On page 20 will be found two useful illustrations of the conditions called Pachydermia laryngis, and Singer's nodes, which show well the difference between them. Each lecture is clinical, and thus we find he compares the ulceration of tuberculosis and syphilis, &c., in one; tumours in another; and so on. In the chapter on anterior nasal examination he says that he uses Duplay's speculum, though most authorities now prefer one of those made with a handle. One is compelled here to remark that the illustrations of instruments are somewhat antiquated. The chapter on the nasal septum lacks reference to the operation now almost universal—namely, submucous resection, which enables relief to be given to many cases almost hopelessly before.

His short description of the accessory sinuses is good, as it follows Hajek throughout, also his list of the various operations on the antrum; though, as is natural, there is not space to discuss the deeper and more difficult bone cells and their treatment. The remainder of the book is devoted to the ear, and the various descriptions are good; especially worthy of note is the chapter describing the ordinary catarrh of the middle ear and the various forms of sclerosis. Fig. 106 is a little misleading, as it is usually advisable to slit the drum head from top to bottom to let out discharge; the small opening figured would close almost immediately. The work can be highly recommended for those who read the German language, and it is nicely arranged, and easy to read.

OSLER'S COUNSELS AND IDEALS. (b)

THIS volume is a collection of extracts from the writings and addresses of Prof. Wm. Osler. In all, forty-seven of his lectures and essays have been consulted. The object of this book is to bring the influence of this master mind to bear more widely upon the medical student. This "individual influence" is, of course, best gained from actual contact with the teacher, but in default of this the present work will do much to fill up the gap. The extracts are arranged

(a) "Lectures on Clinical Psychiatry." By Dr. Emil Kraepelin, Professor of Psychiatry in the University of Munich. Authorised translation from the Second German Edition. Revised and Edited by Thomas Johnstone, M.D., M.B.C.P. Second English Edition. Pp. xviii. and 852. Price 10s. 6d. net. London: Baillière, Tindall and Cox.

(a) "Anleitung zur Diagnose und Therapie der Kehlkopf, Nasen, und Ohrenkrankheiten. Vorlesungengehalten in Fortbildungscursen für practische Aerzte." Von Dr. Richard Kayser, in Breslau. Dritte vermehrte und verbesserte Auflage, Mit 132 Abbildungen. Berlin: Verlag von S. Karger, 1905.

(b) "Counsels and Ideas from the Writings of William Osler." 4s. net. Oxford and London: Henry Frowde, 1905.

under definite headings, constituting altogether twenty distinct subjects or groups. Some of the subjects dealt with are "Pioneers in Medicine," "Catholicity in Medicine," "Charity and Fraternity in Medicine," and "Religion, Death and Immortality." Some of the extracts are of the very greatest value. We quote the following as an example:—"It is the confounded tales of patients that so often set us by the ears, but if a man makes it a rule never under any circumstances to believe a story told by a patient to the detriment of a fellow practitioner . . . he will have the satisfaction of knowing that he has closed the ears of his soul to ninety-nine lies, and to have missed the hundredth truth will not hurt him." And this is but one of the many wise counsels set forth in this admirable volume. We would have every medical man make this book his guide and friend, as by so doing we feel sure that the rough places will be made smoother and the crooked paths straighter. No one can study these extracts without feeling impressed by the nobility of character which stamps each one of them. The volume is tastefully bound, and is printed in clear type on thick paper. It will be found an inspiring book to dip into at odd moments, and one that is sure to be welcomed by a wide circle of the profession.

In sending the first number of the third volume of *Our Hospitals and Charities Illustrated*, Messrs. Macmillan and Co. point out that it has taken up rather a new stand-point, being the first journal that attempts to represent the vast body of people who subscribe to charitable institutions. It contains much that is new and interesting, and attention may be specially drawn to the article on the Salvation Army and the unemployed

OBITUARY.

WILLIAM HUGH HUGHES, M.R.C.S., L.S.A., J.P.

MR. W. H. HUGHES, one of the best known men in Ashton-under-Lyne, died on the 18th instant. He was educated at the Winwick and the Warrington Grammar Schools, and was a student at the Manchester Royal School of Medicine. He took the qualifications M.R.C.S. and L.S.A., and was for a time resident surgeon at the Manchester Infirmary, and afterwards of the Chorlton Union Hospital, Withington. In 1861 he went to live at Ashton-under-Lyne, where he had held many important offices. He had been for a great number of years the medical officer of health for the borough, and was the examining doctor under the Factory and Workshops Acts, the medical officer to the police force, the union workhouse, and the Post-office. He was a magistrate for the borough, and also for the Lancashire county.

THOMAS FRANCIS ODLING, C.M.G., M.R.C.S.

DR. T. S. ODLING, C.M.G., physician to the British Legation, the Telegraph Department, and the Imperial Bank of Persia, died at Teheran on Saturday of typhoid fever. He qualified M.R.C.S. of England in 1872.

HARRY MAY, M.D. ST. AND.

MR. HARRY MAY, M.D., formerly of Ware, Herts, died on the 23rd inst., at Parkstone, at the age of seventy-four. Dr. May studied at the London Hospital and was admitted M.R.C.S. England, L.S.A. in 1852, and L.R.C.P. London, in 1861. He was formerly honorary surgeon to the Loughton Cottage Hospital. He received the M.D. degree from St. Andrew's University in 1880.

JAMES WILLIE HOLMES, M.R.C.S., L.R.C.P.

MR. JAMES WILLIE HOLMES, of Malinda Street, Sheffield, the eldest son of the Rev. T. W. Holmes, passed away at the Charing Cross Hospital, on the 18th inst. A fortnight ago he came to London to undergo an operation, after having suffered for a considerable time from a kidney trouble. The opera-

tion was successful, but the patient had not sufficient strength to rally. Deceased was only forty-three years of age, and obtained his degrees sixteen years ago. He received his training at the Charing Cross Hospital, and has since practised in Sheffield. He was married some years ago, and leaves a widow and one son. The family will have sincere sympathy from a large circle of friends.

BENJAMIN COCKS, M.R.C.S.

MR. BENJAMIN COCKS, M.R.C.S., a Hertfordshire surgeon, formerly of Buntingford, died on the 23rd inst. at Bath, at the age of seventy-three. He was professionally educated at St. Mary's Hospital, and was admitted a licentiate of the Society of Apothecaries in 1858, and later M.R.C.S. Eng., and L.R.C.P. Ed. Mr. Cocks was at one time house-surgeon to the Marylebone Infirmary.

ROBERT KEALY, M.D.

DR. ROBERT KEALY has died at his residence, Ashley House, Gosport, in his seventy-sixth year. Professionally educated at the medical school of King's College, he became a member of the Royal College of Surgeons, England, in 1855, and M.D. St. Andrews, in 1862. Dr. Kealy had been Admiralty Surgeon to Portsmouth Harbour and the Naval Ordnance Department, and physician to the out-patients at the Portsmouth, Portsea, and Gosport Hospital, besides filling many other public appointments in Portsmouth.

EDWARD PILKINGTON, M.R.C.S.

MR. EDWARD PILKINGTON, formerly a well-known medical practitioner in Sunderland, but who had retired and taken up his residence in Harrogate, has died there recently in his eighty-fifth year. He was the author of a "Report to the Registrar-General on the Mining Population of Sunderland."

ALFRED HENRY NEWTH, M.D. ABER., M.R.C.S. ENG

WE regret to announce that while attending a patient at Hayward's Heath on Feb. 22nd, Dr. A. H. Newth had a seizure. A cab promptly conveyed him home, where he became unconscious, and died shortly afterwards. Deceased was the author of many works on insanity. He received his medical education at St. Thomas's, London, and at Aberdeen. He became M.D. Aberdeen, in 1868, and took the M.R.C.S. England a year earlier.

London Inter-Collegiate Scholarships Board.

A COMBINED Examination for a large number of entrance scholarships and exhibitions tenable at University College, King's College, and the East London College will be held in London by the London Inter-Collegiate Scholarships Board on Tuesday, May 15th, 1906, and following days. The Competition is limited to those who have not previously been students at any one of the Colleges *except where the contrary is stated*. No competitor can be elected to more than one scholarship or exhibition. No candidate will be admitted to the examination for these scholarships and exhibitions unless he has passed the Matriculation examination of the London University, or any examination accepted by the University in lieu thereof, or is the holder of a School-leaving Certificate, or is able to furnish some evidence of having had a sound general education which is satisfactory to the Board. Application should be made to the Secretary of the London Inter-Collegiate Scholarships Board, University College, Gower Street, London, W.C., for forms of entry, which must be filled in and returned together with a certificate of age and one of good conduct from the Principal of the candidate's last school or other satisfactory reference not later than May 1st, 1906.

DR. J. A. CLOUGH, Medical Officer of Lagos, takes over the duties of Resident Medical Officer of the Lagos Hospital during the absence of Dr. W. L. Taylor in England on leave.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons in Ireland.—Address on Therapeutic Inoculation.

ON February 10th, Dr. A. E. Wright, Lecturer on Pathology at St. Mary's Hospital, London, delivered an interesting address in the college hall on Therapeutic Inoculation. The chair was occupied by the President, Sir Arthur Chance. Dr. Wright, who was cordially received, dealt at first with the various principles of inoculation, and by means of an excellent series of charts demonstrated the action of inoculation on the opsonic index. He cited a number of cases which had passed through his hands and which had been treated by means of inoculation. As a result it appeared to him that many of the present methods of dealing with particular diseases might be dispensed with if the theory of therapeutic inoculation were properly developed. In his experience he had inoculated cases of appendicitis, suppurative diseases of the kidney, acne, and other forms of pyogenic infection, with good results, and at the moment he was dealing in the same way with a patient who was suffering from leprosy. So far the treatment had given success, but as to the ultimate result he was yet unable to venture an opinion. Dr. Wright then dealt with cases where more than one variety of pathogenic organism was present in the body, and suggested that in such cases it would be well to discover which variety was the most injurious and then to make injections accordingly. He felt that if his system of inoculation was fully developed it would remove a good deal of the medical and surgical methods now in use. If the belief that cancer was the result of the action of a microbe was proved to be true, he felt that in the course of time it would be possible to deal with the disease by means of inoculation.—Dr. Swanzy, in proposing a vote of thanks to the lecturer, said Dr. Wright had acted in the most kindly and unselfish manner in postponing his departure from Dublin in order to give them the benefit of his experience. Even if Dr. Wright proposed to take away all medicinal and surgical practice they could not but feel grateful to him for his address.—Dr. Bennett seconded the vote of thanks, and the motion was carried unanimously.—Dr. Wright replied, and the proceedings closed.

King's College Hospital London.

THE annual court of governors of King's College Hospital was held on the 22nd inst. in the board room of the hospital. The Rev. Dr. Headlam (principal of King's College) presided. The 67th annual report of the committee of management was presented. It stated that the number of in-patients treated during the year showed a decrease of 140 as compared with 1904, and there had also been a decrease in the out-patient department, which was largely due to the construction of Aldwych and Kingsway, and the consequent displacement of the poor population formerly residing in the locality. The ordinary expenditure for the year was £21,487, being a decrease of £333 as compared with the previous year; the ordinary income for the year amounted to £16,200, as against £15,717 in 1904. Legacies were received amounting to £12,270. The committee also reported the resignation, owing to ill-health, of Miss Monk, who for 21 years had held the office of sister-matron. The chairman, in moving the adoption of the report, said that it was necessary that they should bear in mind the difficult task they had before them of keeping the hospital going, and at the same time of collecting sums of money for the removal fund. Owing to the fact that they had received an unusual sum in the way of legacies during the year they had been able to pay their way. It was necessary, he said, that the hospital should have a larger income during the ensuing year. Mr. C. M. Tatham seconded the motion. Sir E. C. K. Ollivant stated that it was hoped to hold a fete during the year for the purpose of raising money for the removal fund. The report was adopted. After some

formal business had been transacted, the chairman made a statement in regard to the removal of the hospital. He said that of the £300,000 they had appealed for they had received about half. They were now in full possession of the site and had a substantial sum in hand to enable them to begin building immediately. The architect who had been selected was Mr. W. A. Pite, F.R.I.B.A., and he had been instructed to prepare the working drawings of the out-patient department, which would be ready in about two months. They therefore hoped to begin the building of that department within the next three months. They had sufficient money to see them to the end of the year, but they required more to complete the hospital. A vote of thanks to the chairman was passed and the proceedings terminated.

The National Hospital for Consumption, Ireland.

THE fourteenth annual general meeting of the supporters of this hospital took place on Friday last at the Royal College of Physicians. The chair was occupied by Mr. O'Brien Furlong, and amongst those present were His Excellency the Lord Lieutenant and the Countess of Aberdeen. The annual report was read, and, as it is a document of considerable practical importance, we hope to deal with it in a special article in our next issue. After mentioning that the new block for women patients was completed, and ready for occupation, early in February, 1905, the report continued: With the completion of this new block the number of beds in the hospital has been raised to 100, thus realising the original scheme of a hospital to accommodate 100 patients suffering from pulmonary consumption. That the subscription list should continue to show an increase is eminently satisfactory; it is evidence of the continued sympathy on the part of the public with every effort made to combat the dread disease of consumption. At the same time the Board would point out the large and necessary increase in the cost of provisions and maintenance consequent on the additional number of beds provided in 1905. The number of daily diets was 43,166 in 1905, as against 36,987 in 1904—an increase of about 16.6 per cent. The report was adopted, and then Sir William Watson proposed, and Dr. Lumsden seconded: "That the thanks of the meeting be given to the Visiting Physicians, Dr. Coleman and Dr. Parsons, and to the staff, for the efficient manner in which they discharged their duties." The resolution was adopted, and shortly afterwards the proceedings terminated.

Diphtheria in Kent Villages.

FIFTY cases of diphtheria have been reported at Well Hall, Eltham, Kent, within a few weeks. All the Sunday schools are closed, and the London County Council day school in Grangehill Road is to be closed if the epidemic continues. Diphtheria has been prevalent in East Greenwich and Charlton since December, mainly among children attending the Lombard Wall School. The school building was disinfected during the holidays, but the disease continued to spread after the term began.

House of Commons.—Bovine Tuberculosis.

MR. BURNS informs Mr. Field that he cannot say precisely when the report of the Royal Commission on Bovine tuberculosis will be issued, but that it is being pressed forward as speedily as practicable. In reply to a further question, the right hon. gentleman states that he could not promise pending this report to introduce a Bill providing compensation to the owners of animals purchased at full market value in open market but subsequently condemned for alleged tuberculosis. Legislation would be necessary to secure a uniform system of meat inspection, but a report to the Local Government Board by Dr. Buchanan, one of their medical inspectors, has lately been issued on adminis-

tration in London with regard to pigs affected by tuberculosis, which will no doubt receive the consideration of local authorities, and will Mr. Burns hopes, lead to some improvement in the present system.

Outbreak of Diphtheria in a Greenwich School.

LAST week the Greenwich Borough Council commenced an investigation which may have important results for London. No fewer than 91 school children in that borough have recently suffered from diphtheria. The great bulk of them are scholars at the Lombard Wall School, and as the London County Council ventilates its main sewers at this particular point the object of the proposed inquiry is to find out whether this is not the cause of the infection. Dr. Annis, the medical officer, believes that the present outbreak has at last been got under. At his request the L.C.C. sent one of its medical men to the school. As a result of two examinations of the children's throats made by him several of the scholars were told to stay away. The school was thoroughly disinfected, but fresh cases appeared among the scholars. The condition of things became so serious that the school was closed for several days in the early part of the present month, and the premises again thoroughly disinfected. As the County Council ventilates its main drainage system at many other places in London, it is felt that evidence from other districts would help Greenwich to arrive at a sound decision. Such an inquiry would be important at the present time, for the several main sewers now being constructed by the L.C.C. involve the erection of sewer ventilators.

The National Physique.

MR. J. G. LEGGE, H.M. Inspector of Reformatory and Industrial Schools, and a member of the departmental committee appointed to inquire into the question of physical deterioration, lectured last week at the London Chamber of Commerce, at the first of a series of joint conferences arranged by the Federation of Working Men's Social Clubs, in conjunction with the Club and Institute Union. Further meetings will be held in March, April, and May. Mr. Legge claimed that the committee, though it had been accused of attempting too much, had performed a very useful service by its study of the question. It was interesting to note that comparison of the results of the anthropometric records secured in 1883, so far as they related to industrial school boys, with measurements taken by himself in 1901 and confirmed in 1903, suggested that their physique had slightly but distinctly improved. The beginning of the remedy was the systematic collection of data, especially relating to children which might be secured by school teachers on a day set apart for the purpose once a year, and by certifying surgeons engaged under the Factory Acts, who annually dealt with some 375,000 persons from 14 to 16 years of age. Overcrowding was one of the chief causes of physical degeneracy, but the children of the suburbs were equal in physique and mentally superior to the purely rural juvenile population; and by opening out the towns as much good would come as by taking the people back to the land. There was need for a stricter suppression of the pollution of the atmosphere; the clearance of insanitary areas; more effective control of common lodging-houses, all beneath the eyes of central medical officers of health. Small holdings and "garden cities" meant much to the future physique of the race. The health conditions of large towns had largely increased in the last half century, but much remained to be done.

The Recent Disturbances at the Royal University of Ireland.

IN Parliament on Wednesday last, Mr. Lonsdale asked the Chief Secretary of Ireland whether he was aware that, in consequence of the disorderly conduct of some graduates and undergraduates at the conferring of degrees on October 27th last, whereby the singing of the National Anthem was forcibly prevented, the Senate of the Royal University of Ireland passed a resolution declaring the urgent necessity of obtaining

powers to deal with all matters connected with the honour and discipline of the University, and whether the Government propose to take the necessary steps to give the Senate power to deal with cases of disloyal and disorderly conduct on the part of graduates and undergraduates of the Royal University. Mr. Bryce replied that he was advised that the Senate of the Royal University already possessed full power to maintain order at all meetings of the University, and to frame such statutes or rules as may be necessary for the purpose.

Annual Dinner of the Association of Medical Diplomates of Scotland.

THE second annual dinner of the Association of Medical Diplomates of Scotland at the Trocadero, London, on the 23rd inst., proved a most successful gathering. The President, Dr. Farrer, was in the chair. The toast of the evening—namely, "The Association," was proposed by Dr. C. W. MacGillivray, President of the Edinburgh Royal College of Surgeons, one of the distinguished guests. The toast of the guests, proposed by Mr. Sydney Stephenson, was responded to by Mr. John Tweedy, President of the English Royal College of Surgeons and by Mr. Bidwell. Other distinguished guests were Dr. Herschell, Dr. G. Carpenter and Mr. E. Canny Ryall. Dr. Skene-Keith proposed the Officers and Council, to which Dr. Hardyman (Bath) and Dr. David Walsh replied. The latter alluded to the exclusion of Scotch and Irish diplomates from most London and many provincial hospital posts.

Increase of Lunacy in Kent.

IN their annual report to the Kent County Council, just presented, the committee state that the condition and management of the asylums at Barming and Chartham are good, and the care of the patients therein have been generally satisfactory, but at the Barming Heath Asylum the accommodation of the number of patients now resident therein is insufficient. Good progress has been made in the erection of new blocks to that asylum for the accommodation of 100 male and 100 female patients authorised by the County Council, but it will be some time yet before the work is complete. The patients at Barming number 1,486, whilst at Chartham there are 1,061. The Commissioners in Lunacy, who had visited the asylum, stated that "on the male side the asylum is overcrowded, there being 34 patients in excess of the proper number, and on the female side there are only 23 vacancies, the accommodation, therefore, which the new additions to this institution will not provide probably under two years, is urgently needed, in view of the fact that during the year 1904 there was an increase of 150 patients over the preceding year. It is therefore clear that even with a smaller rate of annual increase further asylum accommodation for the county of Kent over and above that shortly to be provided at this institution will be necessary in the near future.

Royal College of Surgeons, Ireland. Fellowship Examination.

THE following candidates having passed the necessary examinations, have been admitted Fellows of the College:—A. Charles, L.R.C.S.I. (1902), W. C. Cremin, L.R.C.S.I. (1903), C. A. Cusack, L.R.C.S.I. (1904), T. H. Delany, B.Ch., Royal Univ. Ireland (1893), Captain, I.M.S.

The following have passed the Preliminary part of the Fellowship examination:—S. Blake, Student R.C.P. and S.I.; T. C. Boyd, Student, R.C.P. and S.I.; Miss M. Clarke, Student Bgham. Univ.; J. C. L. Day, Student R.C.P. and S.I.; F. N. Holden, Student R.C.P. and S.I.; J. R. D. Holtby, Student R.C.P. and S. Edin.; A. E. S. Martin, Student R.C.P. and S.I.; E. Montgomery, Student R.C.P. and S.I.; J. Campbell-Murray, Student, R.C.P. and S.I.; K. F. P. Rynd Murray, Student R.C.P. and S.I.; W. G. Ridgway, Student R.C.P. and S.I.; G. W. Stanley, Student R.C.P. and S.I.; and W. M. Woods, Student R.C.P. and S.I.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Chronic Acetanilide Poisoning.—Herrick and Irons (*Journ. of the American Ass.*, February 3rd, 1906) discuss chronic acetanilide (antifebrine) poisoning, and report a case in which the absorption of the drug was from an ulcer of the leg, to which it had been applied for its analgesic effect. The drug appears to be a common constituent of many patent medicines, especially "headache powders," and has a very marked effect, as an analgesic and hypnotic, in such conditions as neuralgia, sciatica, migraine, &c. It is sometimes used by dermatologists as a dusting powder in the treatment of painful or itching skin affections. Withdrawal of the drug from one accustomed to its use is followed by exacerbations of pain, sleeplessness and restlessness, in fact much the same condition as is seen in the morphia-taker. According to Herrick, the acetanilide habit is to be suspected in a patient who presents a secondary anæmia, cyanosis, dyspnoea, nervousness or gastric intestinal disturbance without an adequate explanation for it in heart, lungs or other organs. Splenic enlargement is not uncommon. The urine is dark in colour, darkens still more on standing, and contains an increased amount of conjugate sulphates and also paramidophenol. They suggest that if some of the obscure cases of neurasthenia, anæmia, dyspepsia, &c., were more carefully examined an explanation for them would not infrequently be found in the acetanilide habit, the drug being taken either as such, or as one of the ingredients of the many headache remedies and pain-killers. D.

The "Spleen Point."—Signorelli (*Riforma Medica*, Jan., 1906) has found that the sensibility of the skin is altered in certain places whenever there is inflammation or other morbid process in the spleen. In case of acute tumefaction of the spleen or exacerbation of a chronic tumefaction a zone of cutaneous hyperalgesia, he says, will be found corresponding to the fifth interspace on the left, near the left nipple. This is what he calls the "spleen point"; it may be a little to one side or above or below the nipple. In addition to this zone in front, there is frequently a corresponding zone at the fifth, sixth, seventh, or eighth spinous process, and occasionally another in the side, corresponding to the sixth or seventh interspace on the median axillary line. The zones correspond to Head's sixth metameric segment, and throw light on the embryology and physiology of the spleen, and aid in differentiating affections of this organ. D.

Deep Injections of Alcohol in Neuralgia.—Ostwalt (*Presse Med.*, Paris, Jan., 1906) states that he has made 250 deep injections of alcohol in cases of tic douloureux, and never has had the slightest mishap or unpleasant by-effect. The pain was arrested at once. The effect is like a transient gasserectomy, as for the time being the functions of the Gasserian ganglion are suspended. In at least 90 per cent. of the cases the neuralgia was cured by the procedure. In about a third of the patients recurrence was observed after four or five months, but one or two more injections definitely banished the pain. He injects 1 or 1.5 cc.—80 per cent. alcohol, to which .01 gm. of cocaine or stovain, has been added, making the injection along the trunk of each of the branches affected at the point where they emerge from the bone. He prefers a bayonet shaped needle and has found these deep injections of alcohol effectual in cases of neuralgia elsewhere in the body, in sciatica, &c. He has also cured cases of rebellious facial hemispasm by injecting, a drop at a time, 70 per cent. alcohol along the trunk of the facial nerve. D.

Acute Anglo-Neurotic Edema.—Herter (*Deut. Med. Woch.*, Jan., 1906) describes a case of angio-neurotic œdema in which the œdema developed always after midnight, reached its maximum towards morning, and then gradually subsided during the forenoon. The patient was an otherwise healthy woman of 69. The œdema was restricted to the lower part of the face and tongue. The attacks have recurred at intervals of a few weeks or months during the last eight years. D.

Certain Appearances of X-Rayed Hairs.—Williams (*Journ. British Dermatology*, Feb., 1906) contributes an interesting note on this subject. Complete alopecia was caused by several short exposures of ten minutes each. The hairs showed marked tailing out. In these hairs there was very little pigment found in the attenuated part, and in this part there was no visible medulla. The fine end is often quite pointed, and without any cupping so that it is not easy to decide whether or not they are papillary hairs. This type differs markedly from that of the hairs which result from a single long exposure, timed by the Sabouraud method. In such hairs there is far less tailing out and the hair ends look wedge-shaped. In cases where depilation was not complete the hairs presented a curious appearance. As they grew an attenuated pale portion appeared on the surface, and as the hairs gradually became stronger the natural thickness and colour were recovered. These hairs appear drawn out like a piece of glass tubing. Williams considers that the action of the X-ray on the vegetative function of the hair root and papilla is to cause a weakening of the power to produce cornified cells. The short-tailed hair is the result of the rapid paralysis of this function by a single, long exposure. The long-tailing and pointed ends of the hairs produced by a series of short exposures leading to complete alopecia is the result of a progressive weakening culminating in complete paralysis of this function. The resemblance of the third variety to the narrow portion of a moniliform hair is very striking. Moniliform hairs also occasionally appear in alopecia areata, and this suggests an intermittent interference with the trophic function of the papilla as a cause of moniliform hairs. The keratosis of the mouth of the follicle described by F. Bering is not always present, and if it be a primary condition it may act directly on the papilla and not by mere pressure on the hairs as Bering suggests. K.

The Etiology of Gall-stones.—Lartigan (*Cal. State Journ. of Med.*, Jan., 1906) has recently reviewed the various factors in gall-stone formation, and recorded the results of a large series of personal experiments. The mere presence of an aseptic foreign body does not suffice to produce gall-stones. The introduction of pieces of cotton, fragments of human calculi, grains of wheat, and other irritating substances does not lead to calculus formation, even when the outflow of bile is partially obstructed. The introduction of bacteria, associated with mechanical irritation of the mucosa, is followed in a considerable percentage of cases by the formation of stones; however, this is still more likely to occur if in addition to the organisms there is a foreign body present and the flow of bile be retarded. Out of nine rabbits inoculated and flow of bile partially obstructed, eight developed stones. The chronic cholecystitis produced by the bacteria is associated with desquamation of epithelium and this in turn favours the formation of cholesterol and bile rubin calcium. It is suggested that the clumping of bacteria may be an important preliminary step, the clumped bacteria acting as nuclei for the stones. In

many instances infection takes place from the bowel, but not always so, as many cases of gall bladder infection are due to bacteria not usually found in the duodenum, and there is positive evidence that bacteria introduced into the general or portal circulation may be recovered from the gall bladder. In many cases of gall-stones, no history can be obtained of a general, or even a severe intestinal infection, but these cases may be explained on Adam's theory of latent infection, according to which even healthy intestines allow the passage of bacteria into the portal circulation, and thence into the gall bladder. D.

Food Factor in Paroxysmal Neurosis.—Hare (*Pract.*, Feb., 1906) discusses this subject. In the past these conditions were generally explained as the result of a tendency on the part of the nervous centres to the irregular accumulation and discharge of nerve force, but this hypothesis Hare rejects as not being sufficiently comprehensive. Instead he frames the following provisional hypothesis: "That the recurrent affections—migraine, asthma, major epilepsy, and acute articular gout—depend primarily upon an accumulation of unoxidised, or imperfectly oxidised, carbonaceous material in the blood; and that each paroxysm is a conservative measure adapted to disperse such accumulation." The fate of the hypothesis depends, in the absence of experimental demonstration, on its conformity with verified facts. Hare states that although he framed this hypothesis some seven years ago, he has hitherto failed to find in medical literature any recorded observation which is at all necessarily inconsistent with it. It is generally assumed that when carbonaceous material accumulates in the system it does so in the extravascular tissues in the form of fat, glycogen, &c., but this assumption Hare denies, and considers that such material may, in some circumstances, accumulate in the general blood stream, giving rise to a condition which he terms "hyperpyræmia." He then proceeds to show that the various conditions which favour this hyperpyræmia favour the attacks of the paroxysmal neuroses, while those which are opposed to it tend to ward off the attacks, or are curative of them. In asking for the acceptance of this generalisation, Hare lays down the two following cautions to be observed:—(1) The humoral is but one of a number of factors which together go to make up the causation of these paroxysmal neuroses, and in many cases the other factors were more dominant in causation, and so more worthy of therapeutic attack in the first instance. (2) In many cases the hyperpyræmia determining the paroxysm must be regarded as merely a relative, and not an actual one. K.

Mucous Membrane Lesions in Lupus Erythematosus.—Smith (*Brit. Journ. Dermatol.*, Feb., 1906) corrects the prevalent idea of the rareness of this condition. He made careful examination of fifty-six consecutive cases of lupus erythematosus and found that sixteen had some affection of the mucous membrane, or 28 per cent. The supposed rarity of the condition is doubtless due to the fact that very little complaint is made of it by the patient. The majority of the patients were unaware of the existence of any lesion in the mouth. Some admitted a little soreness which they attributed to the irritation of decayed teeth, but none made any special complaint of the lesions. The list of cases include affections of the inner surface of the cheeks, the palate, inner surfaces of the lips, the mucous membrane of the nose, and the conjunctiva. In no case was the tongue observed to be affected. K.

Clinical Experiences with Marmorek's Antituberculous Serum.—Stadelmann and Benfry contribute an important article to the *Berl. Klin. Woch.* (No. 4, 1906), detailing their results with Marmorek's serum. They point out that since Marmorek's original communication in 1903, numerous favourable reports have been published, but they themselves can confirm none of these. They have given the serum to five patients in the different stages of pulmonary phthisis, and have observed such unfavourable results

that they did not consider themselves justified in giving it to others: They never observed any improvement in objective lung symptoms, and they frequently found that the injections were followed by a week of hectic exhausting fever. Skin affections, such as urticaria, and hæmorrhages, or painful swellings at the site of the injection, were frequent occurrences, and there was often some enlargement of neighbouring lymph glands. The serum employed was obtained almost directly from Marmorek, and was used at first in exact accord with his directions. Later on some modifications of method were introduced with the hope of getting better results, but no good followed the change. The writers give analyses of their cases, which fully support their statements. M.

Progressive Facial Hemiatrophy.—Loebl and Wiesel (*Deuts. Zeits. f. Nervenheilk.*, Bd. 27, 1905) report a case of facial hemiatrophy in a woman, æt. 36. The condition had started at the age of 22, and had gradually progressed. The patient died of pulmonary phthisis, and histological investigation gave the following results:—The skin was atrophied down to its deepest layers; there was atrophy of the muscles supplied by the fifth nerve, and marked changes in the nerve itself on the diseased side, below the Gasserian ganglion; there was, in short, a proliferative interstitial neuritis, and both sensory and motor portions of the nerve were involved in the process. Examination failed to reveal any change in the ganglion itself, or in its cerebral connections, so that the case can locate the disease in the peripheral part of the fifth nerve. M.

Intrathoracic Dermoids.—Drs. Batty Shaw and Williams record (*Lancet*, Nov. 4, 1905) a case of intrathoracic dermoid cyst. The patient, a female, æt. 26, had suffered from pulmonary symptoms from childhood, and was admitted to hospital complaining of dyspnoea, and of the expectoration of phlegm and hairs. Examination revealed all the physical signs of a tumour situated in the upper part of the right side of the chest, while the left chest was normal. The diagnosis was made from the presence of hairs in the sputum. This symptom, the authors point out, is the only pathognomonic one of the condition, and was present in almost all recorded cases which were diagnosed during life. M.

Lobar Pneumonia with Hypoleucocytosis.—Pehoff (*Russische Med. Rundschau*, No. ii., 1905, p. 752) refers to the fact that fibrinous pneumonia as a rule only runs a favourable course when the number of leucocytes in the blood is increased. The author then refers to a case which he had observed, in which the number of leucocytes was greatly diminished, reaching only 2212 per c.m., and yet the case terminated in complete recovery. Careful examination of the case, however, revealed the symptoms of a latent malaria, and the plasmodium was found in the blood. The author found, moreover, that after the pneumonia the number of leucocytes sank still lower, apparently due to the malaria, and he concluded that during the pneumonia an actual increase above the previous number of cells had taken place. This was, moreover, borne out by a differential count during and after the disease, showing that in the former period the proportion of polynuclear cells was much greater than in the latter period. The author concludes that a bad prognosis should only be given when true leucocytosis, as determined by differential counting, is shown to be absent. M.

NOTE.—A summary will appear each week in the following sequence:—

- (1) "Recent Medical Literature."
- (2) "Recent Surgical Literature."
- (3) "Recent Gynecological and Obstetrical Literature."
- (4) "The Recent Literature of Physiology, and Pathology."

NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

EXCLUSION OF SCOTCH DIPLOMATES FROM HOSPITAL APPOINTMENTS.

Any Scotch or Irish diplomates willing to help in the forthcoming protest against their unjust exclusion from nearly all the great general hospitals staff appointments are requested to communicate with Dr. David Walsh, Hon. Sec. A.M.D.S., 18A, Hanover Street, London, W.

BOURNEMOUTH J.P.—The recent trial—Hadleigh Bay v. The Southend Corporation—is of the utmost importance in its bearing upon the responsibilities of local sanitary authorities with regard to the disposal of sewage. The discharge of drainage into the nearest stream or foreshore is becoming more and more perilous to municipal boards. Mr. Justice Buckley's summing up of the case deserves careful study. It is worth while now for almost any one who has been attacked with typhoid fever to enquire as to the possibility of recovering damages from his district sanitary authorities.

THE FORTHCOMING INTERNATIONAL MEDICAL CONGRESS, LISBON, 1906

To the Editor of THE MEDICAL PRESS AND CIRCULAR.
SIR.—The Executive Committee desire me to inform you that it has been decided to issue a limited number of cards of membership to the Medical and Political Press. These invitations will be gratuitous, and applications for them are to be made through the National Committee for each country before March 20th, 1906.

10A Chandos Street, I am, yours very truly,
Cavendish Square, D'ARCY POWER,
London, W. Hon. Sec. for Great Britain and Ireland.

PHARMACY AMENDMENT BILL IN PARLIAMENT.

The exact wording of the notice of presentation of the Bill to amend the Pharmacy Acts is as follows:—"Mr. Winfrey.—Pharmacy.—Bill to provide for the further regulation of the sale of poisons and the compounding of medical prescriptions, and to amend the Pharmacy Acts, 1832 and 1868. Wednesday, February 28th." Mr. Winfrey, M.P., the member for South-West Norfolk, is a pharmaceutical chemist.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 28th.

SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m. Paper:—Captain G. S. C. Swinton, L.C.C.; London Traffic.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.). 8.30 p.m. Papers:—Dr. W. H. Kelson: Some Throat Affections. Dr. P. Stewart: What is the Earliest Stage at which we can Diagnose Tabes Dorsalis? Dr. W. A. Milligan: The Diagnosis of Early Extra-uterine Pregnancy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Hunterian Lecture:—Prof. A. H. Cheate: Some Points in the Surgical Anatomy of the Temporal Bone from Birth to Adult Life.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. T. P. Legg: Clinique. (Surgical.) 5.15 p.m. Lecture:—Mr. J. Pardo: Difficult Micturition and Retention of Urine.

THURSDAY, MARCH 1st.

CHILDHOOD SOCIETY AND THE BRITISH CHILD-STUDY ASSOCIATION (Parkes Museum, Margaret Street, W.).—8 p.m. Lecture:—Miss Miyakawa: Child Life in Japan. (Arranged by the Childhood Society).

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Papers:—Dr. L. E. Dudgeon: Acute Diphtheritic Toxemia with Special Reference to Acute Cardiac Failure. Dr. G. Holmes and J. H. Parsons: The Pathological Anatomy of Amaurotic Family Idiocy.

NORTH EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Clinical Cases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON (Pal Mall East).—5 p.m. Milroy Lecture:—Dr. W. H. Hamer: Epidemic Disease in England—the Evidence of Variability and of Permanency of Type.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Lecture:—Prof. C. A. Morton (Bristol): Some Cases in which Collections of Stones formed in the Prostatic Urethra.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m. Dr. M. Dockrell: Syphilis as it modifies other Eruptions of the Skin, Symptoms, Diagnosis, and Treatment. (Chesterfield Lecture.)

FRIDAY, MARCH 2nd.

SOCIETY OF ANESTHETISTS (20 Hanover Square, W.).—8.30 p.m. Paper:—Mr. C. C. Braine: Experience of Anesthetics in 200 Cases of Prostatectomy.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Hunterian Lecture:—Prof. A. H. Cheate: Some Points in the Surgical Anatomy of the Temporal Bone from Birth to Adult Life.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m. Dr. H. Tilley: Clinique. (Throat.)

MONDAY, MARCH 5th.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos

Street).—4.30. General Meeting. Exhibitions, &c., by Messrs Furniss, Potter, Hugh Jones, J. S. Barr, Secker Walker, &c.

THURSDAY, MARCH 8th.

BRITISH GYNECOLOGICAL SOCIETY (20 Hanover Square, W.).—7.30 p.m. Special General Meeting. 8 p.m. Specimens. Dr. Jellett: I. Advanced Carcinoma of both Ovaries; II. Double Pyosalpinx associated with the presence of a Four Months' Extra-uterine Foetus. Mrs. Scharlieb: I. Endothelioma of the Uterus; II. "Peritelloms" of the Uterus. Papers:—Dr. Jellett: Notes on two rare conditions met with in the Pelvis during Operation. Mrs. Scharlieb: The Advantages of the Abdominal Route in Operations for Cancer of the Uterus.

Vacancies.

Clonmel District Lunatic Asylum.—Assistant Medical Officer. Salary £125 per annum, with furnished apartments, &c. Applications to the Resident Medical Superintendent. (See advt.)

Devon County Asylum.—Third Assistant Medical Officer. Salary £125 per annum, with board, residence, and laundry. Applications to Medical Superintendent, Exminster, Devon.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Metropolitan Borough of Battersea.—Medical Officer of Health. Salary £200 per annum. Applications to W. Marcus Wilkins, Town Clerk, Town Hall, Battersea, S.W.

Nottingham General Dispensary.—Two Assistant Resident Surgeons. Salary £180 per annum each, with furnished apartments, attendance, light, and fuel. Applications to Secretary, M. I. Preston, Journal Chambers, Nottingham.

Royal Cornwall Infirmary, Truro. House Surgeon. Salary £100 a year, with board and apartments. Applications to J. C. R. Crewes, 4 Parkvedras Terrace, Truro.

Township of Manchester.—Assistant Medical Officer. Salary £100 per annum, with furnished apartments, fire, light, washing, and attendance. Applications to James Macdonald, Clerk to the Guardians, Poor Law Offices, New Bridge Street, Manchester.

The London Hospital Pathological Institute.—Director. Salary £250. Applications to Munro Scott, Warden, The London Hospital Medical College, Turner Street, Mile End, E.

Urban District Council of Handsworth, in the County of Stafford.—Medical Officer of Health. Salary £250 per annum. Applications to H. Ward, Clerk, Handsworth.

West Bromwich District Hospital.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Honorary Secretary, T. Foley Bache, Esq., Churchhill House, West Bromwich.

Appointments.

EDGEWORTH, FRANCIS HENRY, M.B., B.C. Cantab., D.Sc. Lond. Honorary Physician to the Bristol Royal Infirmary.

FAYRE, SIR JOSEPH, Bart., M.D. Edin., L.R.C.P. Lond., F.R.C.S. Eng., LL.D. Edin. and St. And., F.R.S., Honorary Consulting Physician to the Falmouth Hospital.

GRAHAM, G. H., M.D. Durh., Assistant Physician in charge of the Electrical Department at the Dreadnought Seamen's Hospital, Greenwich.

LATHAM, HENRY, M.B., C.M. Edin., Assistant Physician to the Peterborough Infirmary.

THOMSON, MAY, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.M.Dub. Honorary Clinical Assistant to the Leeds Public Dispensary.

WALDO, HENRY, M.D., C.M. Aberd., M.R.C.P. Lond., M.R.C.S., Honorary Consulting Physician to the Bristol Royal Infirmary.

Births.

BELLAMY.—On Feb. 20th, at Blandford, Kew Gardens, the wife of Gerald E. Bellamy, M.R.C.S. Eng., of a son.

CROOKSHANK.—On Feb. 24th, at D'Antraques, Barnes, London, the wife of F. Graham Crookshank, M.D., of a son.

GENTLE.—On Feb. 23rd, at 28 Colville Square, London, the wife of J. Alexander Gentle, M.B., C.M., of a son.

STEELE-PERKINS.—On Feb. 20th, at 47 Southernhay W., Exeter, the wife of J. Shirley Steele-Perkins, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of a son.

WAYNE-MORGAN.—On Feb. 17th, Ty Gwyn, Whitechurch, the wife of L. Wayne-Morgan, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

DUNN-FLOOD.—On Feb. 21st, at St. Stephen's Church, Bayswater, Hugh Percy Dunn, F.R.C.S., 54 Wimpole Street, Cavendish Square, London, third son of the late Rev. J. W. Dunn, M.A., Vicar of Warkworth, Northumberland, and grandson of the late Rev. Luke Yarker, M.A., of Leyburn Hall, Yorks, to Marian Sara Georgina, only daughter of John C. H. Flood, of 9 Tavistock Road, Bayswater, and of the Middle Temple, barrister-at-law.

SULLY-KING.—On Feb. 24th, at the Parish Church of St. Mary, Acton, Albert May Sully, M.R.C.S., of Claygate, Surrey, to Adeline, daughter of the late Robert King, J.P., of Durban, South Africa.

COOPER-BARBER.—On Feb. 24th, at St. Michael's, Ravenstone, Edith, second daughter of Rev. H. Barber, M.D., to Arthur Tann r Cooper, M.R.C.S., L.R.C.P., youngest son of William Temple Cooper, of Kingston-on-Thames.

Deaths.

ROUSE.—On Feb. 21st, at Wyndcroft, Worthing, Georgina, widow of the late James Rouse, F.R.C.S. Eng., Consulting Surgeon, St. George's Hospital, etc.

NOTES AND COMMENTS.

Amateur X-Ray Treatment.

THE grave risks attached to X-ray treatment are universally recognised by the medical profession. The method, indeed, is permissible only in the hands of skilled and responsible qualified medical men. Yet in spite of reason and experience some short-sighted members of our profession persist in handing over radiography, and, in some instances, actual treatment by the focus tube, to chemists, electricians, and other unqualified persons. A recent trial in the South of England brought to light an incident of the kind. The plaintiff sued Bridger and Co., chemists, of Bournemouth, for burns inflicted upon his back while undergoing X-ray treatment for locomotor ataxy. There are several points in this case of vital interest to medical men. First and foremost, the patient was sent to the chemists in question by a Bournemouth practitioner. Why should not an expert medical electrician have been chosen for the purpose?

Chemists doing the Work of Medical Men.

HARDLY less extraordinary from our point of view is the fact that Bridger and Co., a well-known and respectable firm of chemists, should have undertaken treatment. It is all very well for them to plead they did so only on the understanding that they were to act under proper medical supervision. As a matter of fact they did nothing of the kind, and the practitioner who sent the patient to them stated in Court that he knew nothing about the special methods involved. Can Messrs. Bridger and Co. fail to realise that in accepting such a commission they were taking legitimate work out of the hands of medical men? However, they no doubt recognise now the folly of such a proceeding, and they would in our opinion be well advised if they gave up radiography also. They can never be safe, as non-medical workers, from claims for damages inflicted by their focus tubes.

Medical Men traitors to their Cloth.

NOR will the moral of the action be likely to fall less forcibly upon the inner consciousness of the medical man who so lightly entrusted his ataxic patient to the tender mercies of a chemist radiographer. In that particular case the tissues of the victim would obviously be extremely vulnerable to traumatism. That fact

would have been recognised and insisted upon had a medical radiographer been called in. In other words, the practitioner would in that event almost certainly have escaped the monetary loss, mental anxiety, and injury to professional reputation entailed by the publicity of his patient's litigation. It is to be hoped that his unhappy experience will act as a warning to others who may be tempted to send their patients to unqualified persons for electrical, massage, and other kinds of treatment.

The Metropolitan Sunday Fund and Hospital Abuse.

THE annual report of the Hospital Sunday Fund issued last week views things for the most part in a highly complacent manner. Everything is for the best in the best of all possible hospital worlds, as surveyed with the rose-coloured spectacles of Sir Edmund Hay Currie and his fellow councillors. Their attitude with regard to hospital abuse must seem ludicrously feeble and ineffectual to those who know the seamy side of the question. Abuse of the kind, they say, in effect, is practically non-existent, what little there may be can be readily checked by hospital authorities. The very sensible suggestion made with a view of lessening abuse, that patients after a first visit should not be permitted to attend a second time without a letter from a local medical man, is dismissed with the curt observation that they do not agree with that proposal. In their opinion it would be better to refer the patient—ye Gods!—to the nearest self-supporting dispensary.

Medical Charities first—Medical Men last.

THAT shows how the Sunday Fund worship their one god—medical charity—and are prepared to sacrifice to him the manliness of our citizens and the livelihood of the medical profession. Their cynical method is to transfer the patients who should be paying small fees to outside practitioners from a general hospital to a paying dispensary. How is the cry of the robbery of the medical profession to be met by substituting two blacks in place of one? Moreover, many general hospitals, such as the London, descend to the incredibly mean practice of charging threepence to each of their poor patients! In that case the Sunday Fund presumably would not advise London hospital patients to be handed on to paying dispensaries in the district. The

fact of the matter is that the main man of the medical profession is absolutely not represented on the hospital funds. The medical men on the Council simply represent the consultant ranks, who have little knowledge or sympathy with the struggles of the general practitioner, and who have not the faintest desire to disturb the serenity of our present hospital system.

LEADING ARTICLE.

LAY NEWSPAPERS AND QUACK ADVERTISEMENTS.

THE harm done to the health and the well-being of the community by the sale of quack medicines and quack nostrums is incalculable. By "quack" we characterise claims advanced by medically unqualified persons to treat and cure diseases by methods that are contrary to scientific experience, and are supported by assertions which are in most cases obviously false, extravagant and self-contradictory. The Medical Acts of the United Kingdom fail to protect the public against either quack practice or quack nostrums. The time has now come, in our opinion, when it is desirable in the interests of the nation that the truth of the whole matter should be stated without fear or favour. This week we propose to draw attention to an advertisement appearing in the *Daily News*. That particular newspaper is not selected because it is one of the worst offenders. On the contrary, its columns, on the whole, contain a considerably less number of objectionable advertisements than the average daily journal. The editorial tone of this publication we regard as genuinely high, and it is precisely on that account that we press this question upon its consideration. A certain Professor Heynel, unknown to the medical *Register*, advertises to cure asthma, consumption, chest and stomachic complaints. He advertises himself as a specialist of twenty-five years' standing and director of an institute at Brighton, but offers free consultations at an address in Shaftesbury Avenue, London. In all the diverse conditions mentioned he offers complete cure. Suppose a patient to have cancer of the stomach or lungs, or general tuberculosis, or advanced disease of heart, lungs, pleura, or stomach, this omnipotent professor undertakes, according to his advertisement, to cure them all. This claim is, on the face of it, absurd and misleading. As it is advanced with a view of getting money from the public it follows that it is fraudulent. Its appearance in the columns of the *Daily News* makes the Editor of that journal *particeps criminis* in the attempt to procure money under false pretences. What has the Editor of that journal to say in defence of the advertisement in question? With the ingenuity that characterises the quack advertiser, the unhappy Editor is represented as giving his direct and personal support to the claims of Professor Heynel, by means of the following passage:—"We cannot impress upon our readers who suffer themselves (or whose friends are in distress

through these terrible diseases) too much the importance of immediately putting themselves or their friends in immediate communication with the Director of the Institute." We can only sympathise with the Editor whose hospitality has been purchased and betrayed in so base a manner. As a matter of fact, we believe the Editor of the *Daily News* to be a moral and social philanthropist of the highest order. How he can reconcile his principles with the publication of such wicked and mendacious advertisements is a mystery indeed! There can be no doubt that Professor Heynel has had to pay a large sum of money to have a three-quarter column advertisement inserted in the *Daily News*. Nor can there be any doubt that the lay newspaper press generally draws an enormous revenue from quacks and quackery. In later issues we propose to extend our analysis of the situation to other journals, but for the present we are concerned with the *Daily News* alone. Let us ask the Editor if he realises the potential harm done by such advertisements as those of "Professor" Heynel. The very fact of the issue of so costly an advertisement indicates the large sums that must be secured therefrom. If the Editor of the *Daily News* accepts our view that the advertisement is inherently false, then he is not only being made the catpaw of a charlatan, but is sharing in his profits. We fail to see any other logical reading of the position. The fact that such advertisements are universally inserted in lay newspapers is no excuse for individual cases. The editors of journals drawing profits from such a source are earning money for proprietors and shareholders from base quarters. The victim of the charlatan for the most part come from the ignorant of all classes, but especially among the poor. Too often the sufferer from some serious malady is led into the use of advertised "cures"—save the mark—at a period when his condition is not, humanly speaking, past hope. To cure the incurable is the alluring lie of the quack—and to fill his pockets his one gospel. Let us implore the *Daily News* in future not to play into his hands and to lend its powerful aid to the furthering of heartless frauds upon the community. There has been one honourable exception in English journalism to the practice of receiving objectionable advertisements in our contemporary *Truth*—although what we should call quack remedies have now and then crept into its columns. One suggestion we would make to lay editors is that they should henceforth rigorously exclude from their advertisements those that have appeared in the black-list of *Truth*. Next week we purpose saying a few words about the yellow press, by the side of which the *Daily News* appears as a comparatively mild offender.

JAMES HENRY MITCHELL, a Kendal butcher, for sending to the London Meat Market the carcass of a cow which was slaughtered while suffering from milk fever, was last week sent to prison for a month. The farmer who sold him the cow was deprived of his costs of coming to the Guildhall as a witness.

NOTES ON CURRENT TOPICS.

Chronic Alcoholic Leptomeningitis.

DR. SPALDING LAURIE, writing in the *Australian Medical Gazette* for November 20th, records three cases of chronic alcoholic leptomeningitis. The patients all seem to have been pretty heavy drinkers, and, though syphilis could not be excluded absolutely, no evidence of its having occurred was obtained in any of the three. The first patient was taken suddenly ill with head-ache and giddiness; he had some retching and a tendency to fall to the left side. Four days later there was well-marked paresis of both hands and arms, but there was no other evidence of nervous disease. After slight improvement under potassium iodide and mercury, he became rapidly worse, with headache and giddiness, and died three weeks after the first seizure. *Post-mortem*, no lesion was found, but thickening of the arachnoid and pia mater over the frontal lobes. The second case was one of eight years' duration. The illness began with twitching of the right hand, which was followed five years later by similar symptoms in the left. Three years subsequently the lower limbs were affected with formication and "pins and needles," and gradually the power of walking was lost. Stupor then supervened, accompanied by coarse tremor of the hands, lips, and eye-lids. *Post-mortem*, the brain was œdematous and its veins were engorged, but the skull and dura mater were healthy. The arachnoid and pia were much thickened over the Rolandic area on both sides and slightly over the frontal lobes. The last patient, a heavy drinker, was attacked with left hemiplegia and rapidly became comatose. He died in two days. Besides recent hæmorrhages in the right lateral ventricle, the pia and arachnoid were thickened and slightly opaque over the frontal and Rolandic areas. The author points out that his cases are instances of a rare condition, and each differed from the usually-described type in that the dura, which is generally implicated in alcoholic meningitis, was free, the thickening being confined to the pia and arachnoid and no part of the brain substance involved. He then discusses the differential diagnosis from paralysis agitans, general paralysis of the insane, and tumour. He shows that the special points to look out for are head-ache, vomiting, Jacksonian epilepsy, tremors, paresis, inco-ordination, optic neuritis, delirium, loss of memory, and mental failure. Any or all of these may occur according to the extent of the pressure on the brain.

Scientific Education.

THE report of the Committee on Technological Education appointed nearly two years ago by Lord Londonderry was issued last week, and in its main features will be generally approved by scientific men. The fact, long known to everyone outside Government offices, that England is far behind Germany and America in the opportunities and

machinery she provides for scientific and technical training, is duly acknowledged by the Committee. They recognise the importance of keeping this country in a line with its competitors as "essential," and dwell on the lack of facilities for instruction, the lack of co-ordination among existing institutions, and the lack of appreciation by employers of the value of technical training. Teachers should be drawn from the highest ranks in their professions, say the Committee, and should be provided with the chance of pursuing pure scientific investigations, unhampered by routine drudgery. A large scheme of consolidation and extension of the Royal College of Science, the Royal School of Mines, and similar institutions is then recommended, and a suitable governing body indicated. We understand that the Board of Education is prepared immediately to find £20,000 a year to promote the scheme, and it may therefore be assumed that it will go forward. Although primarily concerned with the advancement of industrial technique and training, we are sanguine enough to hope that the presence of Sir William Church on the Committee is a guarantee that the ancillary medical sciences have not been overlooked in this provision. £100,000 a year to prevent disease and death would be the best investment the Government of a country ever made.

Small Hospital Schools.

THE decision of the King's Hospital Fund not to give grants to those hospitals which allocated a portion of their general funds to the maintenance of their medical schools is making things embarrassing for some of the smaller schools. Evidence of this was given last week by the annual report of the Middlesex Hospital, and by a meeting called at the Westminster Hospital to consider the question of the maintenance of its medical school. The Middlesex Governors' appeal is almost pathetic. They have come to the end of their available capital and are anxiously considering how the difficulty is to be surmounted unless some substantial aid is forthcoming soon. At the Westminster meeting it was resolved to open a separate fund for the maintenance of the school and to ask subscribers to the hospital to allow the Committee discretionary power to use part of their subscriptions for the use of the school. Whilst it is plain to everyone who thinks on the matter that hospitals are the only places where doctors can be trained, it is not equally clear to the public that a school is a positive asset to a hospital and its patients, both directly and indirectly, and we hope that these two worthy institutions will be successful in their endeavours to raise money to carry on their work. They are unluckily suffering from the bad advice originally given to the King, who, at the inauguration of his hospital fund, was made to say, through Lord Knollys, that no money given to it would go to support any medical laboratory. The want of accuracy and courage with which the anti-divisionists were met by the King's advisers on that occasion can only be sincerely lamented.

"Progress."

We have been asked to notice the arrival of a new journal, entitled "Progress," in the field of literature. This we are very glad to do, and can wish our infant contemporary nothing better than that its aims may be rapidly and effectively realised. The object of "Progress" is to secure social advancement for the poor and the raising of the standard of the industrial livelihood, and so long as the *desiderata* are approached on economically sound lines and by natural, as opposed to artificial, channels, we are heartily in accord with the editorial plan. The frequency with which our countenance is sought by journals of this and others of kindred nature shows how much the practice of medicine is becoming bound up in the practice of sociology, and how much is expected of the profession in that domain of effort. By assuming responsibilities in connection with the health of the people, medicine is being drawn more and more into civic paths, and its influence, and the influence of its knowledge, is becoming more and more warmly recognised. So long as the profession lends, as it is always willing to lend, its skill, its training, and its technical advice to the cause of social reform, and so long as it keeps clear of party politics as such, it is difficult to assess what its future influence for good may become.

Medical Care of Sailors.

At the annual meeting of the Seamens' Hospital Society, last week, Sir George Vivian, Deputy-Master of Trinity House, was in the chair, and made some pertinent remarks about the medical care of merchant seamen. He spoke of the "methods of barbarity" by which the sick sailor of old was treated by the members of the ship's company, usually the mate, who did doctor's duty, and he expressed his own desire to see ship's officers compelled to pass an examination in first aid, surgery, and pharmacy before qualifying under the Board of Trade for their strictly professional duties. Those who are read in the works of Mr. Frank Bullen and other writers of the sea as it used to be can only shiver at the thought of what the tender mercies of the mate as a doctor must have been, and one cannot wonder that the typical sailor of a hundred years ago should be represented as saying:—

"If my maxim's disease, 'tis disease I shall die on."

The prospects of recovery must indeed have been remote, and the period intervening before death a pretty ghastly one. Doubtless merchant seamen have experienced the benefit of the greater spread of humanity of late years, but even humanity without skill is of little avail in time of sickness. The efforts of the St. John's Ambulance Association to promote some knowledge of first aid among ships' officers have met with some voluntary response, but we warmly associate ourselves with Sir George Vivian's demand that

a simple medical and surgical training should be compulsory for all officers of the mercantile marine.

Consumption at the Cape.

HAPPY indeed is that country which can tackle its tuberculosis problem with some prospect of finality! A vigorous effort is being made at Cape Town to rid the town of both its consumptives and its consumption-breeding areas, and the promoters maintain that it is possible if their suggestions are carried out for the Table Mountain City to be permanently freed from the infection of the disease. It appears that, like all large cities, Cape Town has its slums and over-crowded quarters, and that in these, which are chiefly occupied by natives, tuberculosis is rife. Dr. Forsyth of that city is urging that these quarters should be purged of their unhealthy elements, and that the sufferers should be transported to the high-and-dry regions in the Karoo desert, there to form an open-air colony. Such an arrangement can only make the dwellers in the old cities of Great Britain jealous of the facilities offered by new countries for dealing so effectively and so comfortably with the curse of consumption. Land in the Karoo cannot be expensive, and a colony, we take it, could be made almost self-supporting through the work of the patients who were able to undertake light agricultural duties. The climate, too, of the desert is an ideal one for consumptives, and under good management the recovery-rate should be high. But it seems certain that if the authorities undertake this venture they will put down their foot firmly against the importation of further tuberculous cases; indeed, the Cape Colonists, like the New Zealanders, are getting very restive at the dumping of British consumptives on their shores. If they adopt restrictive legislation, with a view to putting a stop to it, one would find it hard to blame them.

Anti-Vivisection Strategy.

If the obvious difficulties or the repeated failure of frontal attacks show that a position cannot be carried by a *coup de main*, the strategist lays his plans for preparing a flank attack, or for sapping and mining up to the enemy's stronghold. The anti-vivisectionists have long fought in the open field, and some of them are now beginning to recognise that but small successes are likely to accrue from this method of warfare. A different plan of campaign has been adopted in certain quarters, and, as it is both specious in its claim to attention and insidious in its effect, it is well that it should be fairly and squarely recognised. The form it is taking is that of asking for exemption of different classes of animals from experiment, and the immediate question to be laid before Parliament this Session is whether dogs shall not be saved from the "vivisectionist." Now, as the dog is "the friend of man" in a more intimate sense even than the horse, it is certain that such an appeal will touch the hearts of a large number

of people who would not be worried by a more general and sweeping proposal; and, moreover, a Bill to this effect being short would stand a very good chance of passing in the allotted time. On the other hand, if it did find its way to the Statute Book, an important precedent would be established and it would not be difficult in succeeding Sessions to get other classes of animals protected by similar short measures. Strategically, then, the move is well planned, and it will need all the more skill on the part of opponents to defeat it. We need hardly repeat that if experiments on animals are immoral, it is immoral to experiment on a dog as on a guinea-pig, perhaps more so, as the dog is capable of presenting greater resistance to his captors, and if experiments on animals are valuable to medical science, no animal which is likely to help in the defeat of disease should be excluded from the field.

Aberdeen's Lord Rector.

SINCE Sir Frederick Treves, by his retirement from active practice, became "unmuzzled," he has been playing the part of candid medical friend to a good many audiences, and he maintains the character he has always borne as a vigorous and emphatic speaker. Unfortunately, the emphatic speaker is apt to over-emphasise the particular side of the question that he wishes to present, and consequently an erroneous impression is apt to result in certain instances. Elected Lord Rector of Aberdeen, Sir Frederick Treves gave his constituents the customary Rectorial address at his installation, and in it he dwelt in strenuous terms on the advantages and disadvantages of the doctor's life. He paid a warm and well-deserved tribute to the unostentatious heroism of the country doctor—"the man in the gig"—who drove by day and by night to distant cottages, bringing healing and comfort to the poor and the sick. Admirable, too, were his words as to the necessity for absolute honesty in the practice of medicine, a calling apt to lend itself to euphemisms and prevarications. But we can hardly follow the Lord Rector when he argued that money and social influence were not only not advantages, but positive disadvantages in following the career of medicine. To speak thus is to fly in the face of evidence that is obtainable on every hand, and to cite cases like that of Sir James Paget is only to prove the rule by pointing out the exception. Though money and social influence are not the only factors in medical success, they are powerful adjuvants against which it takes men of worth, ability, and pluck to struggle. How many even of the good men in the leading practices of their districts to-day would be there if they had found themselves after qualification without a shilling in their pockets?

We understand that the Worshipful Company of Goldsmiths have made a grant of £10,000 to the Institute of Medical Sciences Fund of the University of London, on the assumption that a site for the institute will be provided at South Kensington.

PERSONAL.

THE Council of the Royal Institute of Public Health has appointed Professor Elie Metchnikoff to the post of Harben Lecturer for the present year. The annual congress of the institute will be held at Cork from June 27th to July 3rd, under the Presidency of Professor Bertram Windle, F.R.S., President of the Queen's College, Cork.

WE regret to learn that Mr. A. H. Benson, F.R.C.S., has resigned the Secretaryship of the Royal Medical Benevolent Fund Society of Ireland, a post which he has held for the past twenty-four years. The central Council of the Association has passed a resolution accepting Mr. Benson's resignation with deep regret.

DR. COOPER, M.P., who has sat on the London County Council as senior member for Bermondsey for over seventeen years, has resigned in consequence of the pressure of his newly-acquired parliamentary duties.

SIR WALTER FOSTER was last week elected chairman of the Medical Members Committee at the House of Commons. Seven members out of the ten constituting the committee were present.

DR. BEVAN LEWES, the well-known Director of the Wakefield County Asylum, entertained the Medico-Psychological Association and delivered an important address on alcohol, crime and insanity.

A HANDSOME presentation was made at South Normanton last week, to Dr. W. J. Le Grand, who for about eleven years lived in the place, but recently left for Blackwell.

MAJOR-GENERAL Lord Cheylesmore last week presided over the quarterly court of governors of the Brompton Hospital. The medical Committee's report showed that very satisfactory results were experienced by patients treated at the Sanatorium and Convalescent Home, but there was an urgent need for funds towards its maintenance.

IN the absence of Lord Ludlow, president of the Cancer Hospital, London, Lieutenant-Colonel Thomas R. Parr took the chair at the annual general meeting of the governors last week.

IT is stated that Dr. Norman Walker, of Edinburgh, will, next autumn, again offer himself as Direct Representative for Scotland on the General Medical Council. At the last election he ran second to Dr. William Bruce, of Dingwall.

PRUDENTIAL ASSURANCE.

FEW of our readers can have any conception of the extent to which life assurance is now carried on, and it augurs well for the thrift of the community that its adaption is increasing by leaps and bounds. If we take as an example the annual report of that gigantic institution the Prudential Assurance Company now before us, we arrive at the figure of 773,051 as the number of life policies in force at December 31, 1905, assuring, with bouns, £85,944,245, and producing a premium income of £4,118,360 per annum; whilst the life annuities payable are 3,369 in number, and amount to £114,081 per annum. In the Industrial branch the number of policies in existence at December 31st last was 16,065,268, including 1,102,267 free or paid-up policies, and the amount assured £159,683,044. The weekly premiums receivable in respect of these policies amounted to £122,626 per week, or £6,376,552 per annum.

A CLINICAL LECTURE

ON THE

CAUSE AND THERAPY OF ELEPHANTIASIS.

By Professor HANS KUHN, M.D.,
Of the Allgemeinen Poliklinik, Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

It may be interesting and instructive to follow the history of a case of elephantiasis that came to the out-patient department seeking relief from her burden, that had gradually invaded the left leg.

The patient, a female, was *æt.* 45. Her father died when *æt.* 71, of apoplexy, while her mother died at 62 from some pulmonary trouble. She has three brothers alive perfectly healthy, and no trace of her present illness could be found in any of her ancestors. When *æt.* 7, she suffered from scarlet fever, complicated with nephritis, but since that time has been comparatively healthy. Her menses commenced when *æt.* 14, and have continued regularly since, with pain on suppression. She often suffered from hemicrania ophthalmica when the menses were approaching, but was relieved with their advent.

In 1891, she first observed her left leg commencing to swell, which soon became much thicker than the right around the thigh, and which had become the seat of repeating erysipelas, accompanied with high fever. During the intervals between the attacks the skin never recovered its normal colour and softness, but continued thick and hard. From the first attack this annual recurrence has added to the thickened condition which is greatest over the inguinal canal, and extends down to the knee. The skin, formerly soft and smooth, now became thick, hard, and warty, subsequently forming knobs that hung in folds from the front of the thigh till the weight and dimensions became so great that it was a burden for her to move.

In 1896, she fell on the door-step and contused the lower third of the tibia without breaking the skin of the left leg. This was followed by a black area that soon ulcerated, forming a large sore as great as the palm of the hand, which necrosed and discharged a large quantity of *debris* before it healed, leaving a deep irregular cicatrix. After four or five years' repetition of the erysipelas, the extremity became unwieldy, which was accompanied with difficulty of breathing and cardiac palpitation; her corpulence, but not fat, had become so burdensome that she sought relief in every quarter without avail, which finally brought her to the poliklinik.

Her report on admission was medium height, corpulent, bony structure good, and muscles well developed. The right leg is enormously thickened, but the left far surpasses it, especially in front, where the swelling from the inguinal region down the front of the left leg lies over on the right like a monstrous labial hernia, extending almost to the knee. The skin of the left leg at the knee is drawn into folds and greatly thickened. A side view represented two tumours, one behind reaching down to the knee-joint about the size of a child's head, and the other in front as described. The skin over the calf of the leg was enormously thickened and swollen, extending down to the irregular cicatrix. The whole cutaneous surface was rough, irregular, and warty, while the parts between the folds of thickened skin were red and swollen, exuding an evil-smelling fluid with epithelium, but nowhere were excoriations or ulcers to be found.

The internal organs were:—Lungs, normal, sound on percussion, with a few dry bronchial rales on auscultation at the base. The area of cardiac dulness was greatly enlarged, extending from a line a finger's-breadth outside the mammary line towards the right to the external margin of the sternum and upwards to the fourth rib. The apex beat was found in the fifth intercostal space about an inch outside of the

mammary line. Auscultation revealed a dull sound without a murmur over the auricular region, which was slightly accentuated on the second sound. The action of the heart was slightly energetic and irregular. The liver and spleen were not enlarged, and all the other internal organs normal. The urine was wine colour, specific gravity 1014, and of acid reaction. There was a slight sediment, containing lymph cells and squamous epithelium. The indican of the urine was increased, while albumin was found in a small quantity. The nerve system was entire, while the

lymphatic glands were enlarged over the left inguinal region, but no tenderness or pain was present, neither was there sclerosis of the arteries observed. The radial pulse was moderately tense, unequal, and slightly arrhythmic, although the vessel was soft and full. The lips and mucous membrane were cyanotic, while the patient breathed slowly and with difficulty. Nothing pathologically was observed, internally or externally, about the genitals.

On account of the presence of myo-cardiac insufficiency, which was indicated by the dull cardiac tone, irregular movement, dilatation, and cyanosis, and presence of albumin, operation was considered a dangerous undertaking. Iodide of potassium was prescribed, while the extremities were raised and liquor Burowii, or a solution of alum and acetic acid, applied to the limbs, and then swathed in bandages. This was continued for several weeks without any visible sign of reduction. It was then resolved to operate, notwithstanding the danger of anæsthesia. On October

14th, a large wedge-like part of the upper tumour was removed, and from the incisions exuded a large amount of reddish-yellow fluid. The cut vessels were wide, both venous and lymphatic, but by pressure and bandages the parts were tightly brought together and kept in position with a few stitches and sterilised gauze. The wound rapidly healed without rise of temperature, but a large amount of lymph drained from the wound. On October 21st, the first change of bandages was made, and on the 23rd the stitches were removed. Sixteen days after operation the patient was again out of bed.

This favourable result encouraged a second operation on November 22nd, when another tumour about the size of a child's head was removed from the inner side of the thigh. After careful coaptation and stitches the wound again healed. On this occasion drainage tubes with injections of the tincture of iodine were applied to the lymphorrhœa, and the patient left hospital on December 27th.

To illustrate the effects of the operation, I present two photographs. The first gives a side view before operation, while the second shows the leg from behind.

THE MEASUREMENTS TAKEN BEFORE OPERATION.

	Right Leg. cms.	Left Leg. cms.
Over the instep	27	29
Around leg above malleolus....	32	34
Around calf of leg	52	59
Around middle of patella	48	69
Around middle of femur	60	84
Around upper part of femur....	70½	90

AFTER OPERATION.

Over instep	27	29
Around leg above malleolus....	32	34
Around calf of leg	52	59
Around over patella	48	69
Around over middle of femur ..	60	74
Around over upper part of femur	70½	80

The weight of the first tumour removed was 2,900 grammes; the second, 1,300 grammes.

The patient is now able to move about freely, doing light duties which were quite impossible to be performed before the operation, and besides feels much better in health. The left leg is unchanged in dimensions, and above the normal proportion, but the right is still abnormally large, but the patient is pleased with her present condition, and refuses to undergo any further operations.

The etiology of this disease may be considered as an indigenous pathological change brought about by trophic disturbances, and may be classed along with Dr. Favarger's "Autochthoner Elephantiasis" as the following macro- and micro-scopic results show:—

The excised tumours contained a mass of œdematous fibrous tissue, the cut surface resembling the section of a ripe pear with fibrous bands running through it as we meet with in hard, chronic œdema, with gaping blood vessels whose walls are greatly thickened. The lymphatic vessels are greatly increased in number, while thickened and distended in the same manner as the blood vessels. Large quantities of small cells were found in the infiltration irregularly distributed. Lymph vessels, arteries and veins were greatly thickened in their tunica media and adventitia. The perivascular tissue was also filled with nuclear and small-celled infiltration. The general appearance was that of a subcutaneous chronic inflammation with congestion, hypertrophy, hyperplasia, and other elementary forms.

The congenital forms of elephantiasis usually commence with chronic œdema and other anomalies in the circulation, which exposes the tissues to any infecting agent like cocci or septic germs, which set up chronic inflammation, thickening, and final deformity.

We may consider two forms possible in temperate zones, viz., that arising from varicose veins, eczema, infection from strepto- and staphylo- cocci, periphlebitis with ulceration, and œdema, all leading on to disorganisation and profuse lymphorrhœa.

The second form arises after repeated attacks of erysipelas recurring without any apparent cause on a healthy surface, which after healing leaves behind a thickening of the tissues and may go on for years. The skin finally gets hard, thick, and warty, with tubercles here and there; the follicles begin to atrophy and the hair fall out, while the general increase goes on till the elephantine deformity is produced. It may be seen from the two forms described that the case recorded is a mixed one and partakes of both before the operation.

In conclusion, it may be noted that the case described yielded favourably to the operation; although somewhat risky, under the morbid conditions of the heart, it would have been hazardous to press it further. In the temperate zone these cases are not so frequent as in the torrid zone, where filaria is a potent factor in the transmission of the disease.

The treatment may be internal as well as external. The internal medicine has not met with that success frequently attributed to it, although purging, sweating, iodide and its salts, with decoctions of Zittmanni and arsenical preparations, have been said to check the progress of the disease, but never cure it. Considering the etiology of the process, it is reasonable that internal and external treatment should proceed together, as the elastic hard bands on the extremities cannot be reduced by internal applications. Compresses with lead and iodide plasters tightly applied often reduces the swelling for a short time but is not always successful, although attention is given to diet, heart, and kidneys.

Operating is not a new method of treating elephantiasis, as it has been practised freely before and since the introduction of antiseptic surgery, either by the wedge operation or extirpation of the whole morbid mass. In other cases the tying of arteries supplying the morbid areas has often sufficed to reduce the tumour, but this is very untrustworthy.

English and American surgeons who have to deal with the filarial type in tropical regions tell us how tumours varying from 20 lbs. to 100 lbs. have been

removed without any inconvenience or danger to the patient, but sporadic cases like the above appear to be more exhaustive or more difficult to manage from heart and renal complications, as the mortality is always high (75 per cent.) in the temperate zone. The first of these operations was performed by Maddox-Titley at St. Christopher in the West Indies, when a tumour, 70 lbs. in weight, was removed from the scrotum. It is more frequent in males than females in hot countries, but apparently the opposite in temperate latitudes. Considering the high mortality of 75 per cent. in temperate climates it becomes a serious matter to decide if ligaturing the artery is not the best and safest for the patient, as it seems to succeed admirably in the hands of some surgeons. Following up this idea of cutting off blood supply, Dufouin contrived an instrument with a pelotte arrangement for compressing the femoral artery. The operative treatment before antiseptics led surgeons to adopt this form of treatment more frequently than at present, or since the introduction of Listerism, still, in temperate climes it is preferable to operating when the heart or kidneys are at fault. We therefore conclude that the correct treatment of elephantiasis is first to discover the real condition of the circulation, renal organs, and, as far as possible, the probable etiology of the disease. If either the circulation be bad or the kidneys be diseased, there are very grave apprehensions of sepsis and gangrene supervening which may prove fatal. When such conditions exist it is better to diet the patient, administer internal treatment with external applications such as bandages, compresses, &c., or, if some minor or local operations can be performed under local narcosis, they may be undertaken without much risk to the patient.

NOTE.—A *Clinical Lecture* appears in each number of the journal. The lecture in next week's will be by George Herschell, M.D.Lond., Senior Physician to the Queen's Jubilee Hospital on the Routine Examination of the Fæces in General Practice and what we may learn from it.

ORIGINAL PAPERS.

ON PARTIAL GASTRECTOMY FOR PYLORIC TUMOUR. (*)

By WILLIAM TAYLOR, M.D.DUB. UNIV., F.R.C.S.I. Surgeon to the Meath Hospital and County Dublin Infirmary; Surgeon to Cork Street Hospital; Member of the Council Royal College of Surgeons, Ireland, etc.

My object in bringing forward this communication is not that of recording any personal triumph but of eliciting a discussion which may be alike interesting and instructive. The patient is a woman, æt. 60, who was sent to me in the month of July, 1905, by Dr. Wessels, Assistant Master, Coombe Hospital.

The history she gave on admission was that for about three years prior to this she had suffered on and off from pain in the abdomen and stomach trouble of an ill-defined character to which she applied the term "weakness."

For the last three months of her illness she said the pain had become so aggravated as to compel her to lie with her stomach pressed against the side of her bed, or to roll in agony upon the floor.

During this period she was quite unable to make use of anything in the form of food. Everything she ate was vomited very soon after. The vomited matter was generally frothy and consisted principally of what she had recently partaken, but, on several occasions during the few weeks immediately preceding her admission to hospital the vomited matter was dark—as she termed it "like porter." Almost three months previously she had discovered a lump in the stomach, but it was only during the few weeks immediately before coming to hospital that she noticed it increasing very rapidly in size.

On examination, we saw a thin, emaciated woman, whose face was drawn into innumerable wrinkles and furrows from suffering. The skin was simply hanging on her bones and so far as age was concerned she looked nearer eighty than sixty years. She was almost edentulous, and her general appearance would be best appreciated by saying she was a cadaverous looking old woman. On inspection of the abdomen one could easily see projecting through the attenuated walls a tumour situated a little above and to the right of the umbilicus.

On palpation the tumour felt hard and irregular, and was obviously quite adherent to the abdominal wall. There was no rigidity of the abdominal wall, and the patient did not complain of any tenderness. On percussion the stomach was thought to be dilated, but there was no splashing.

Dr. Craig saw the patient with me and we both formed the opinion that the case was one of carcinoma gastræ possibly supervening upon an old-standing ulcer. This opinion we formed from the age and appearance of the patient, from her thin, emaciated condition, from the history of three years' trouble prior to the formation of a tumour, and from the rapidity of the growth of the tumour as well as from its strong, hard, irregular nodular character. A test breakfast was given next morning and the contents of the stomach subsequently withdrawn and examined for free hydrochloric acid, but with a negative result.

From our previous opinion this was only what was anticipated. Operation did not seem to hold out much prospect of relief or cure, but on consultation with Dr. Craig I decided to place the matter fully before the patient, explaining the gravity of any operation in her then state of health, as well as the very small likelihood that her condition could either be ameliorated or cured, with the result that I was given a free hand to act as we thought best, as, she said, her life was then utterly unbearable from pain and vomiting. Three days later, the patient being meanwhile put through the usual preliminary preparations of feeding and cleaning of the mouth, we operated.

The abdomen was opened through the right rectus and on passing the hand within, the tumour was found firmly adherent to the abdominal wall. As there was no discoverable evidence of secondary involvement of the liver or other structures in the neighbourhood save a couple of enlarged glands in the lesser omentum, and as we saw that by excising the portion of the abdominal wall to which the tumour was adherent, the growth could easily be withdrawn, we determined to act accordingly and perform a partial gastrectomy.

The anterior portion of the sheath of the rectus muscle over the tumour was then dissected up, leaving apparently quite healthy muscle underneath. The rest of the abdominal wall to which the tumour was adherent was then excised by an elliptical incision and the stomach with the tumour and portion of the belly wall withdrawn. The growth presented all the naked eye appearances of cancer, which seemed to have been pyloric in origin, well limited towards the duodenum but spreading along both curvatures of the stomach.

The greater and lesser omenta corresponding to the amount of stomach I decided to remove were ligatured and cut off. The coronary artery was double ligatured and two large clamps applied across the stomach, so that section of the stomach could be made between them at a point which would leave at least two inches of apparently healthy stomach between the growth and the point of section. The stomach was divided by the knife, and the pyloric portion with the tumour being well wrapped up in sterilised sponges was pulled well over to the right and left hanging over the right side of the abdominal wall. The cut edges of the cardiac side were then rapidly sewn together with a medium sized silk suture applied continuously, the sutures passing through the entire thickness of the stomach walls and pulled sufficiently tight to be hæmostatic as well as co-optive. The clamp was removed and there being no sign of bleeding a second continuous suture of fine silk

(*) Paper read before the members of the Surgical Section of the Royal Academy of Medicine in Ireland, January, 1906.

taking up only the sinews and muscular coats was then applied so as to enfold the first row.

The duodenum being freed by incising the peritoneum to the right of its second portion was clamped and section made between $\frac{1}{2}$ in. and 1 in. below the growth. It being then determined that the cut edges of the duodenum could be easily approximated without tension to the back of the stomach beyond the sutured edges, this procedure was carried out as described by Kocher, by a double row of continuous sutures of fine silk. What was taken to be the œsophagus during this procedure was then found to be a constriction of the body of the stomach due to the cicatricial contraction of an old standing ulcer, producing an hour-glass condition of the stomach.

It was obvious that, to close the abdomen and leave such a constriction about $2\frac{1}{2}$ inches to the left of the gastro-duodenal junction we had effected, would necessitate, in case of recovery, a further operation at a date not very distant. The patient's condition being very good and as only some 40 minutes had elapsed from the time the operation started, I decided to perform gastropasty for the hour-glass constriction, which was accordingly done in the usual way. The lines of the suture were then sponged with warm saline solution, the packing removed and the edges of the abdominal wall adjusted, the defect in the rectus being remedied by transverse suturing of the posterior portion of the sheath and overlapping of the anterior part of the sheath. Repair was rendered easy by the relaxed state of the abdominal walls. The resulting cicatrix is everything that could be desired. The completed operation occupied exactly 70 minutes and the shock was not at all severe.

The subsequent course of the case I will not weary you with, suffice it to say that there never was any symptoms until the present moment which caused us the slightest apprehension. Her progress to recovery was uninterrupted and rapid. The method of feeding was that adopted after any ordinary gastro-enterostomy. On the fourth night after operation she asked for some albumen water, but the moment the nurse proceeded to get it, the patient got out of bed and, in spite of all the nurse could do or say, walked round the ward. On speaking to her next day about the risk she ran in acting in this fashion, she told me she merely acted as she did in order to see how she could get along after going through so much. The only effect of the midnight peregrination seemed to be that of producing a sound sleep of almost seven hours. Fish was given on the tenth day, and she was allowed up on the fourteenth day, and left hospital for the convalescent home, Bray, on the twenty-third day, able to eat meat without pain, discomfort, or sickness. Since then she has remained in perfect health and as she expressed it to me last week, "she has no pain, never vomits, can make use of anything she gets, and in fact feels grand."

On making a section through the tumour and portion of stomach and duodenum removed, the centre of the growth was found to be occupied by a circular ulcer with sharply cut edges, the surrounding tissue being dull and hard. A small piece was cut out of the edge of the ulcer and adjacent tissue and examined by Dr. Boxwell, who informs me he believes the tumour to be merely a mass of indurated inflammatory tissue around an old-standing ulcer.

The points on which I would be glad to elicit discussion are the question of the differential diagnosis of inflammatory growth around old-standing ulcers from carcinoma gastrici and the treatment of undoubted gastrici carcinoma. In connection with the first of these points much has been written, but so far as I know a reliable diagnosis cannot be made even with the abdomen opened. Mr. Moynihan at the discussion in connection with the surgical treatment of chronic gastric ulcer at the annual meeting of the British Medical Association, August, 1905, stated that he believed he could then reliably distinguish the inflammatory tumefaction

from the carcinomatous condition after opening the abdomen, but I think the points upon which he laid most stress are not by any means infallible. Numbers of cases have been considered absolutely hopeless by even the most experienced surgeons, any attempt at removal of the tumour being looked upon as utterly impossible. The palliative operation of gastro-enterostomy was performed as it was said, to render the last few weeks or possibly months of life more endurable, but the subsequent results upset all calculations previously formed about the nature of the growth, as the patient got perfectly well. In several such cases the abdomens were opened subsequently for other conditions and on examining the stomach all evidence of tumour formation had disappeared, the only sign of any pre-existing pathological lesion being a cicatrix or puckered condition of the stomach wall or pylorus. With regard to the second point—viz., the treatment of cases of undoubted carcinoma gastrici much difference of opinion still exists. In endeavouring to arrive at an opinion on this point one should compare the average length of life of patients suffering from carcinoma who remain unoperated upon, the average duration of life of such cases after the performance of the so-called palliative operation of gastro-enterostomy, and the average duration of life of patients after the performance of partial or even complete gastrectomy. The mortality of the two operative processes mentioned should also be contrasted.

Von Mikulicz has published the results of his experience so far as this inquiry is concerned from the observation of no less than 458 cases. (I take this very largely from his article in Von Bergmann's Surgery, Vol. 4.) The average duration of life of the unoperated cases was a little over eleven months.

The average duration of life of cases upon which simple exploratory laparotomy alone was performed was nearly fifteen months. If these groups are added together we get the average duration of life as about thirteen months from the onset of the disease, and this is the figure Mikulicz takes as his basis for determining the results of the operative treatment of gastric cancer. The average duration of life after the performance of gastro-enterostomy was in 145 cases a little over 12 months—that is a little less than the average duration of life of the unoperated cases, calculating from his basis as taken above. The average duration of life after gastrectomy (partial or complete) was performed was $24\frac{1}{2}$ months. When these statistics were published, of 20 cases of gastrectomy then living, 4 were alive, and without any sign of recurrence for over $3\frac{1}{2}$ years, while no less than 10 cases were alive over 2 years.

As regards the mortality of these two procedures, the comparison is also interesting. The mortality of the operation of gastro-enterostomy stood at no less a figure than 26.5 per cent., whereas the mortality of gastrectomy, which up to 1898 had stood at 46.5 per cent., has since that date fallen to 25 per cent. Clairmont, in a paper based on 258 operations on the stomach from Professor Eiselberg's clinic, says out of a series of 77 cases of malignant disease of the stomach excision of the growth was performed in 24 with a mortality of only 3 eq. 12.5 per cent.—a truly phenomenal result. The average duration of life after gastro-enterostomy in this series of cases was 200 days as contrasted with 400 days after partial gastrectomy.

All surgeons at the present time will readily concur that where it is possible to perform gastrectomy partial or complete, for gastric carcinoma, this is unquestionably the proper procedure to adopt, but no very good purpose can be served by endeavouring to draw a comparison between the average length of life after the performance of gastrectomy and gastro-enterostomy respectively, for the operations are performed in totally different conditions. The cases in which the palliative operation of gastro-enterostomy was performed were cases too far advanced for gastrectomy. A true comparison could only be drawn if a large number of cases had been taken in all of which gastrectomy could have been easily performed, but in

half of which gastro-entrostomy was done while gastrectomy was performed in the remainder. Then the average longevity of one might more fairly have been contrasted with that of the other. But one could scarcely conceive a surgeon deliberately performing what at best could only be a palliative operation, while it was possible to perform a radical operation, and by this means give the patient even a slender chance of complete cure. There is, therefore, no good to be gained by following the hypothesis further. The operations are performed in patients who have reached totally different stages in the progress of the disease, and the results should not be contrasted.

After the performance of gastrectomy a few cases may be said to have been permanently cured, while life in others was prolonged from one to four years in tolerably good health. A comparison of these results with the absolute futility of medication, high frequency currents and other non-operative methods of treatment, renders the great benefit of operation more apparent. Mikulicz says "the results of gastrectomy compare very favourably, as regards duration of life after operation, with the results of operations for cancer of the tongue and rectum, and are not very much worse than those of operations upon cancer elsewhere in the body, the surgical treatment of which is recognised as justifiable." He sums up his conclusions on this subject by stating that "in view of the considerable number of patients who die within a few days after operation and the still greater number who live only a few weeks, one must conclude that gastro-entrostomy for cancer of the stomach is an operation of little value and one which is likely to be performed less and less often." And from these facts "One must admit that resection of the stomach when it is technically advisable is the best palliative operation for gastric cancer."

Moynihan, in his recent book on "Abdominal Operations," gives prominence to this expression of opinion when he says "the question may arise as to whether gastrectomy should not be performed deliberately as a palliative operation in cases where an early secondary deposit can be seen in the liver, or, inaccessible or irremovable glands are found in the pancreas, or along the aorta or vena cava, if we take into account the following advantages of gastrectomy as compared with gastro-entrostomy. That a prolongation of life for 10 months longer than the period given by gastro-entrostomy is the rule. That the comfort, general health, appetite and well-being of the patient are all emphatically better, and; "finally, that the patient has always a chance, even though it is of the slenderest, of a complete recovery from this disease."

The first of these alleged advantages I have already dealt with above, with the second I fully concur, but I must say I fail to see what "slender chance of complete recovery" a patient can have after gastrectomy for cancer if "inaccessible or irremovable glands are found in the pancreas, or along the aorta or vena cava, or if a secondary deposit is seen in the liver." My own opinion is that one is not justified in performing gastrectomy for cancer if secondary deposits are seen in the liver, or if glandular involvement exists to such an extent as to be impossible of removal, though the operation of gastrectomy may be technically possible it is not under such circumstances, I think, "technically advisable."

The comparatively small number of cures that are effected must be attributed to our inability to make a diagnosis sufficiently early. In how few cases do we see a diagnosis of carcinoma *gastri* made before a tumour can be palpated, and it has been stated that when a cancerous condition of the stomach has progressed so far as to give rise to a palpable tumour the case has by that time passed beyond the sphere of radical operation with any prospect of cure. That this statement is very largely true is obvious from the fact that one frequently sees cases in which a tumour can be palpated only with the greatest difficulty, it seems small and quite freely movable, yet, when the abdomen is opened a few days later with the idea of performing a radical operation, the area of infiltration is found to be

so extensive along the lower curvature that even a completed gastrectomy cannot be performed. There seems to be little or no definite ratio between the size of the tumour palpable through the abdominal walls and the extent of the disease one finds within.

Occasionally one finds a comparatively large tumour on palpation, and on opening the abdomen there is but little infiltration of the stomach wall—at any rate so far as the fingers and naked eye can detect. Mr. Moynihan's advice on the question of diagnosis is an eminently practical one: "to better our results we must explore, not to confirm, but to make a diagnosis."

ON TORSION OF THE SPERMATIC CORD.

WITH REPORT OF A CASE.

By J. LACY FIRTH, M.S.LOND., F.R.C.S.,

Surgeon to the Bristol General Hospital.

TORSION of the spermatic cord is a rare condition, and one which has seldom been recognised before the affected parts have been laid bare by operation. I believe most surgeons would consider the possible existence of the condition if confronted with a case in which severe pain and swelling in the groin had attacked a male possessing an imperfectly descended testicle on the affected side. But I suspect that few of us, when considering the diagnosis of acute painful enlargements of the fully-descended testicle, are in the habit of recollecting that the cause of the swelling may be torsion. I confess that in the past such has not been my custom, and that, partly for this reason, when at last I met with a case of testicular swelling from that cause I failed to recognise its nature. The nearest approach I made to a correct diagnosis, if I may speak of approaching that which I left so distant, was to recognise that the case was peculiar, and one which I did not fully understand. Later, finding this mental position uncomfortable, I took the downward step of attributing the swelling to a cause entirely different from the real one. The following are the notes of the case:—

W.S., æt. 23, a labourer, came to my out-patient department at the Bristol General Hospital on Friday, August 5th, 1904, complaining of pain and swelling in the right testicle and scrotum. These troubles had begun five days previously without known cause. No strain or blow had preceded their onset. There had been an attack of vomiting at the beginning, but none later. The first symptom had been pain, chiefly in the groin, and the swelling of the testicle had been first noticed [a] few hours later. For five days the swelling had gradually increased and the pain continued.

Examination showed the right testicle swollen to the size of a large hen's egg and very tender. The organ felt heavy and firm. It was most firm posteriorly. In front, in the upper two-thirds, deep fluctuation could be elicited. The spermatic cord and vas deferens felt absolutely normal above the swelling. The scrotum on the same side was reddened and slightly œdematous.

There was no history of venereal disease, and the urine was clear and free from gonorrhœal shreds or other deposit. Rectal examination showed that the prostate was normal, and that there was no enlargement of the vesiculæ seminales.

After questioning him, the man stated that on two occasions, one two years, the other eight weeks previously, a swelling had descended from the groin of the same side (right), with uneasiness rather than pain, and had remained for a few hours. On each occasion this had been dispelled by rubbing the groin. He described the present swelling as having descended from the groin in a similar way. (I surmise that at least, in the present instance the pain in the groin had led to the patient's misconception on this point. During the whole time he was under my observation, there was no sign of any abnormality in the groin.

It seems not unlikely that the groin troubles on the other two occasions were the result of a slight degree of torsion of the spermatic cord, and that coincidentally with the friction the torsion had disappeared.)

The man was first treated as an out-patient, but at the end of ten days, no improvement being manifest, I admitted him as an in-patient. On the eighteenth day of his illness I explored the swelling, which had changed very little, though if anything it had increased a little in size and become slightly redder and more painful, with a needle and syringe, using full antiseptic precautions. The needle was passed twice into the deeply fluctuating area in front. About one drachm of blood-stained fluid was withdrawn. I considered the fluid to be inflammatory effusion in the tunica vaginalis secondary to some form of testicular inflammation. A further period of rest in bed was ordered. During the following ten days discomfort rather than pain was felt in the testicle. On the thirty-second day of the illness ether was given, and I exposed the testicle by incision. For a day or two previously there had been a return of pain, and the skin had become more reddened and adherent to the parts beneath and fluctuation more distinct. At this period I held the view that most probably the trouble was of tubercular origin, the more because there was a strong family history of phthisis.

At the operation the skin and subcutaneous coverings of the testicle were found to be œdematous and about three-quarters of an inch thick. The parietal layer of the tunica vaginalis was also thickened, and in some places directly adherent to the visceral layer, in others separated from it by blood-clot. From the uppermost part of the sac, however, about a drachm of turbid yellow fluid escaped, and this had an offensive odour. The testicle and epididymis were soft and mottled greyish-yellow and brownish in colour. Immediately above the testis, in the highest part of the tunica vaginalis, the spermatic cord was found to be twisted, the condition being recognised by the spiral course of the dilated veins and by spiral grooves. It was not difficult to untwist the cord. To completely do this the testis had to be rotated certainly through two half-turns. At the time I estimated the degree of twisting to be three half-turns. The epididymis was a little swollen, but had not a hæmorrhagic appearance. It lay obliquely along the uppermost border of the testis, the latter having its long axis almost horizontal. Though the testicle and epididymis had their long axes almost horizontal there was a slight inclination of these downwards, outwards and backwards, and the globus major was slightly lower than the tail of the epididymis. The twisted part of the spermatic cord, which was entirely within the cavity of the tunica vaginalis, had a vertical length of about half an inch. The testicle, at this stage, the adhesions to the tunica vaginalis having been separated, hung suspended from the top of the tunica vaginalis by a short length of twisted spermatic cord. The twisted cord provided, in short, a pedicle by which the testicle was suspended in the vaginal cavity of the tunic, and the organ had no other attachments. As the testicle was obviously gangrenous, it was removed with its tunic. The spermatic cord was ligatured about half an inch above the twisted portion, where it appeared quite healthy. The wound was closed, a small drainage-tube being inserted at the lower end. Primary union followed, the wound running an apparently aseptic course. Before operation the patient's temperature had fluctuated between 98° F. in the morning, and 99° in the evening. After operation the morning temperature was usually 98° and the evening 98·4° or 98·6°.

Examination of the parts removed, after preservation for some weeks in formaline solution, shows that the twist was from within out, or in the direction opposite to that of the movement of the hands of a watch. When the cord is untwisted by one half-turn, the globus major and the upper pole of the testicle to which it is attached are brought from an inferior, posterior and external position to one superior, anterior

and internal. Another half-turn in the same direction carries the globus major again to a posterior and external position, but leaves the long axes of the testicle and epididymis horizontal. It seems a little uncertain whether the testis was twisted another half-turn during life or not. If the testicle is given another half-twist, *i.e.*, a third, in the direction opposite to that of the original twist, the free border of the upper pole of the testicle will be directed forwards; in other words, the testicle will then be horizontal, with the tail of the epididymis directed backwards, that is, will be in a position of combined "anterior inversion." and "horizontal inversion." It is certain that the testicle before torsion of the cord occurred had the abnormal position of "horizontal inversion." I believe now, as a result of a careful examination of the specimen, that the degree of torsion was two half-turns, and that before torsion the testicle had the abnormal position of horizontal inversion, but not that of anterior inversion. In addition, the testicle is in shape more flattened from side to side than normal.

The organs were not cut into until they had been hardened in formaline for several weeks. The section shows that for one-third of an inch at the periphery the testicular tissue is white in colour, but the central parts, the rete testis, and the whole of the epididymis are of a homogeneous, dull brick-red colour. The red colour must be due either to the previously-congested state of the affected parts or to congestion together with extravasation of blood.*

The chief facts of interest in the case recorded above may be summarised as follows:—A young adult, with the testis (right) completely descended, but possessing the anatomical peculiarities of being suspended freely in a horizontal position from the top of the tunica vaginalis by a pedicle of mesorchium, was attacked rather suddenly with severe pain in this testicle, followed in a few hours by swelling of the organ and œdema and redness of the scrotum, and on the thirty-second day, an exploratory puncture having been made on the eighteenth day, the cause of the trouble was found by operation to be torsion of the spermatic cord and gangrene of the testicle.

The first recorded case of torsion of the spermatic cord appears to be that of Delasiauve in 1840. The next, in order of publication, were those of Scarenzio in 1859, Langlet in 1871, Langton in 1881, and Nicoladoni in 1885. Nicoladoni thought he had discovered an undescribed affection when he published his first case, and must have been unaware of the earlier publications mentioned above. To the present time between forty and fifty cases of torsion have been recorded. The best account of the affection with which I am acquainted is that of André Lapointe in a small monograph entitled, *La Torsion du Cordon spermatique et l'Infarctus hæmorrhagique au testicule*, 1904, and I must here express my indebtedness to that writer for many of the facts, considerations and references given.

Of volvulus of the testis between forty and fifty cases have been recorded. In addition a number of cases have been recorded in which the testicle had passed into a state of hæmorrhagic infarction, like that produced by torsion of the cord, but in which no such torsion was found.

Causation of Volvulus of the Testicle.—The testicle, with normal anatomical arrangements, rests upon the posterior wall of the scrotum, much in the same way as certain parts of the colon rest upon the posterior abdominal wall, and has only a partial covering of serous membrane. There is no mesorchium or mesotestis composed of two layers of serous membrane, and comparable to the mesentery of the small intestine. With these arrangements volvulus of the testicle is probably impossible. The one constant abnormality found in cases of volvulus appears to be the presence of a more or less elongated mesorchium or mesotestis and the suspension of the testis in the cavity of the tunica vaginalis by this mesorchium. It is this mesorchium, forming a suspensory pedicle for the testicle, and containing the spermatic cord, which becomes

* For a more complete pathological report see Postscript.

twisted. This relation of the testicle to its fibrous tunic is analogous to that of the heart to the pericardial sac. In one exceptional case, recorded by Lexer*, the twisted pedicle suspended the testicle, but not the epididymis. The torsion had taken place between the globus major and the superior pole of the testicle. The rest of the epididymis was unattached to the testicle, and lay outside the tunica vaginalis.

It is important to remember that the testicle with a twisted cord has been found perfectly descended and imperfectly descended about an equal number of times. The essential cause of torsion is not therefore imperfect descent of the testicle, but, as we have seen above, the formation of a mesorchial pedicle. In its abdominal position, before descent, the testicle possesses a mesotestis or mesorchium. During the normal descent of the organ this mesotestis disappears. With imperfect or delayed descent, just as with complete descent, the mesotestis may or may not persist. The persistence of a mesotestis does not necessarily cause either imperfect or delayed descent of the testicle, though no doubt it favours these occurrences by interfering with the natural action of some of the forces which normally produce descent. Hence a testicle retained in the groin is more likely to have a mesotestis than a testicle which has passed into the scrotum. Many of the victims of torsion of the cord gave no history whatever of imperfection or delay in the descent of the affected testicle. In fact, a testicle provided with a mesotestis may reach the fundus of the scrotum before birth, and therefore without recognisable delay in descent. Possibly a fully-descended testicle with a mesotestis is more liable to torsion than a testicle with a mesotestis remaining in the groin, for in the former case the mesotestis is more likely to be elongated and attenuated.

In addition to having a pedicle, the testicle, in cases of torsion, has frequently had the abnormal position in the scrotum of either "horizontal inversion," or "vertical inversion," or "anteversion." In horizontal inversion the long axis of the testicle and epididymus is horizontal. In vertical inversion the change of position is the same in kind but greater in degree, and the globus major lies below and the globus minor above. In anteversion the epididymis is in front, and the free border of the testis faces backwards.*

In these cases it would appear that during descent the testis has been more fixed at its lower than at its upper pole. The upper pole has therefore descended relatively more than the lower, and the testicle has passed into the position of horizontal inversion, and either remained in that position or passed from it to that of vertical inversion, pivoting as it were in these movements upon its lower pole. Kocher has shown that when the testicle pivots in this way on its lower pole the descending upper pole drags with it most of the vessels of the spermatic cord, and separates, to a certain degree, a vascular fasciculus from a deferential fasciculus in the cord. With these fasciculi separated in horizontal inversion, producing the so-called "bifurcation of the cord," it is easy to realise that a smaller degree of torsion will effect a greater degree of vascular obstruction, through one fasciculus compressing the other, than if the torsion takes place with the fasciculi close together, as in the normal cord. In some of the recorded cases of torsion with infarction of the testicle the degree of torsion was only one half-turn. Horizontal inversion existed in most of these cases, and affords an explanation of the great effect of the small twist. Various abnormalities of

the tunica vaginalis have been found with torsion of the testicle, such as persistence of the funicular process with or without a hernia. It is obvious that the more roomy the tunica vaginalis the more easily can the testicle within become rotated. Lastly, the shape of the testicle has been abnormal, e.g., flatter than usual, or pear-shaped in some cases.

Symptoms.—The age of patients with this affection has varied from four months (Dowden) to sixty-two years (Nicoladoni). The symptoms comprise those produced locally and those at a distance, the latter being the reflex effects of compression of the nerves in the cord. At first the pain may be lumbar or iliac, but soon passes into the testicle. The abdomen may be rigid and retracted, and the thigh flexed. Vomiting is frequent, and has been known to become stercoraceous (Whipple and Nash). Syncope, pallor and sweating, with a rapid and feeble pulse, are common symptoms. In nearly all cases the onset of severe symptoms has been sudden, an important diagnostic point. In a few cases, however, the onset symptoms have not been severe, and the patients have then been able to walk and even work for a day or two. Later, in these cases, the symptoms became more severe, and compelled the patients to take to their beds. In another group of cases the symptoms have quickly subsided, but the patients have remained liable to recurrences. In Van der Poel's case, for example, the patient, a medical man, 25 years of age, had had many such attacks, usually during the day, but occasionally coming on at night during sleep. Sometimes he had two attacks in one day, sometimes months passed without an attack. The patient, after a time, discovered that the cause of his trouble was torsion of the testicle, and that he could relieve himself by rotating his testicle in the opposite direction. Gifford Nash has recorded a case in which he successfully relieved a youth with torsion by untwisting the cord. The symptoms had lasted an hour and a quarter. A tender swelling of the cord itself above the swollen testis helped Nash in making the diagnosis. Subsequently the affected testicle became smaller than the other.

Diagnosis.—Hitherto a correct diagnosis of torsion of the cord has been rarely made. The confusion has most often been with incarcerated or strangled hernia. But in torsion intestinal obstruction is not absolute, and vomiting not as a rule persistent. It is in the cases of torsion of the imperfectly-descended testicle that confusion with hernia is most likely to occur. The mistake could hardly be made if the testicle were fully descended, unless an irreducible hernia was present at the same time, for otherwise the inguinal canal would be free. If a strangulated hernia of the partial variety (Richter's) occurred in association with an undescended testicle, the difficulties in diagnosis would be very great. Dowden* points out that in strangulated hernia the swelling and pain begin almost simultaneously, whereas in torsion the swelling follows the pain.

When the cord of an undescended testicle is twisted the condition has also to be distinguished from the other disorders which may affect such a testicle, viz. from the so-called strangulation of the undescended testis, and from inguinal orchitis. The first of these, strangulation of the undescended testicle, produced, it has been supposed, by the pressure of the pillars of the external abdominal ring upon the testicle suddenly extruded between them, or upon the cord of a testicle so extruded, cannot be distinguished clinically from torsion. Godlee and de Quervain † have reported cases of strangulation of this kind without torsion. The condition seems to be an extremely rare one, and it is highly probable that in most of the cases in which the diagnosis of strangulation has been made the real condition present, though unrecognised, was torsion of the cord. It is equally probable that many cases which have been regarded as examples of inguinal orchitis have been really examples of torsion, though

* *Arch. f. klin. Chir.*, 1894, xiv. 311. 201.

* I have adopted the English and French phraseology for these abnormal positions of the testicle. German Surgeons use similar terms in a rather different sense, and by *inversio verticalis* mean that the change of position is round the vertical axis of the testis, and by *inversio horizontalis* that it is round the horizontal axis, both being either complete or incomplete. Thus the "Inversio verticalis" of the Germans is the anteversion of the English writers, and the "vertical inversion" of the English is the complete "Inversio horizontalis" of the Germans.—*Vide Lehrbuch der Urologie*, Von Leopold Casper, 1903, p. 323.

* *Scottish M. S. & J.* 1901, ix. 329.

† Quoted by Lapointe, *Op. cit.*, p. 103.

naturally a testicle in the groin is not exempt from the forms of inflammation which attack the fully-descended organ, e.g., gonorrhoeal or traumatic orchitis.

When the cord of a fully-descended testicle has become twisted the condition has to be distinguished from epididymitis, epididymo-orchitis, or orchitis of urethral or other origin, suppurative inflammation of the tunica vaginalis, tubercular disease of the testicle, ruptured, varicocele, and acute hæmorrhagic infarction of the testicle. The difficulty in these scrotal cases in the past has been no doubt chiefly due to the fact that, torsion has been regarded as an affection of the imperfectly-descended testicle only. The local symptoms are not pathognomonic, but the sudden onset of the pain, the rapid swelling of the testicle and its coverings, and the associated abdominal symptoms and collapse should enable one to recognise the disease if its possible existence is borne in mind.

Prognosis.—No case of torsion of the spermatic cord yet recorded has ended fatally. The testicle itself has, in at least three cases, been saved by timely detorsion. Two cases of this kind have been mentioned above, and a third is recorded by Perry.* In all the other cases the testicle has either been removed by castration, or has sloughed, or has atrophied. As pointed out by Lapointe, there are eleven cases on record in which the cord was untwisted by open operation, and the testicle not removed. In one additional case the testicle was left to its fate without untwisting the cord by Langton.† In that case, and in six of those in which the cord was untwisted, the testicle was subsequently eliminated in a septic state. The records of three only of the remaining five report the ultimate fate of the testicle. The fate was atrophy. They are the cases of Von Meyer, Bryant, and Defontaine. The question arises, Why did the testicle slough in the other six cases? It is significant that in all there had been an operation. No testicle with torsion of the cord has been spontaneously eliminated by septic processes without a previous operation. The fate of a testicle which has undergone hæmorrhagic infarction from torsion would seem then to be simple atrophy, partial or complete. If gangrene ensues it is the result of superadded infection. The path of infection may be either the wound inflicted by the surgeon or possibly the blood stream, the contamination of the blood having taken place elsewhere in the body.

Treatment.—The methods of treatment available for torsion are as follow:—

- (1) Detorsion by taxis.
- (2) Detorsion through an incision.
- (3) Detorsion, with fixation of the testis in the scrotum (orchidopexy), including transplantation if the testis is imperfectly descended.
- (4) Castration, immediate or secondary.

Detorsion without fixation of the testicle is not ideal treatment, for it leaves the patient liable to a recurrence of the trouble. Detorsion with fixation of the testicle in the scrotum in such a way that recurrence will be rendered impossible is the method of choice if it can be satisfactorily carried out. Immediate castration is required, first, if the testicle has become infected and is gangrenous; and, secondly, if detorsion and orchidopexy are found impracticable or have been tried and failed. If a non-infected hæmorrhagic testicle is left after detorsion and the wound remains aseptic, a portion of the gland at least may survive to be of use in the economy. If, however, the wound becomes septic, gangrene of the testicle will almost certainly follow, and secondary castration become necessary.

POSTSCRIPT.—Since the above was written and published Dr. Newman Neild, Pathologist to the Bristol General Hospital, has kindly examined sections of the testical and epididymis microscopically, and furnished me with the following report:—

"On transferring the specimen from formaline into spirit, the dark colour disappeared, and was replaced

by a pink colour. The nuclei of the seminal tubules do not take hæmatoxylin stain, and the protoplasm is granular. The nuclei of the interstitial fibrous tissue and the septa do not take the hæmatoxylin stain except near the corpus Highmori; here there are numerous cells with irregular nuclei, which take the stain, but not so well as normally. The blood vessels are filled with degenerated blood corpuscles. There is no extravasation of blood. In the epididymis many fibrous tissue cells take the stain, and degeneration is not so well marked here as in the epithelial part of the organ. The tube in the epididymis shows deeply-stained spermatozoa.

"The condition of the organ is histologically suggestive of the condition found in an anæmic infarct of the kidney."

In nearly all the previously recorded cases of torsion of the cord in which the affected parts were exposed and inspected they were found to be in a state of hæmorrhagic infarction. In my case, the microscopical examination of the specimen shows that the testicle and epididymis were not hæmorrhagic, but rather in a state of anæmic infarction or simple necrobiosis, though the tunica vaginalis contained effused blood. The only explanation of this fact I can suggest is, that in my case, either from the beginning or from a very early period, there was arterial obstruction as well as venous obstruction, but I am unable to explain why the arteries should be obstructed in this case, and not in nearly every other recorded case.—J. L. F.

CLINICAL RECORDS.

TWO CASES OF RENAL CALCULUS IN CHILDREN UNDER TEN.*

By W. GIFFORD NASH, F.R.C.S.Eng.,
Surgeon to the Bedford County Hospital.

CASE I.—G. C., a boy, æt. 8, was admitted into the Bedford County Hospital on May 27th, 1905, with a history of abdominal pain and frequency of micturition since an early age. The left kidney could be distinctly felt. The urine was acid, and contained pus, but no crystals were found. *Operation:* The left kidney was exposed by a lumbar incision and a stone was felt in its pelvis. The cortex was incised and a stone weighing 30 grains was removed. Seven small calculi were washed out of the kidney. A tube was inserted and the wound sutured. Urine escaped from the loin for a few days. The child made a good recovery. The size of the main stone shows that it had been present in the kidney for a considerable time. The presence of the small stones suggests that others may have been present and may give rise to further trouble.

CASE II.—E. C., a boy, æt. 4, was admitted into the Bedford County Hospital on October 11th, 1905, with an indefinite history of renal calculus. For two years he had occasionally passed blood in his urine and complained of feeling cold in his belly. At times he cried at night and screwed his legs about. The urine contained a trace of albumin, but no pus or crystals. There were no other symptoms of stone in his kidney no frequency of micturition, no attacks of vomiting, no swelling, and no renal tenderness. But there was one definite piece of evidence. Three skiagraphs were taken by Mr. King, the house surgeon, and in each, in the region of the left kidney, was a very distinct shadow. Exploration of this kidney was decided on, and the kidney was first exposed, and then brought out of the lumbar incision. Some hardness in the renal pelvis was felt, and puncture with a needle showed this to be a stone. A small incision was made in the renal cortex and a grooved director passed into the pelvis; next the wound was enlarged with a blunt forceps and the tip of the index finger. The stone, which was felt lying in the renal pelvis, was seized with a pair of forceps and delivered with some difficulty owing to its peculiar flat shape. Then followed a

* Read before the Society for the Study of Disease in Children, February 16th, 1906.

* Birmingham M. Rev., 1898, xliii. 279.

† St. Barth. Hosp. Rep., 1881, xvii. 188.

continual welling up of venous blood from the kidney. Attempts were made to arrest this by ligature of some vessels, which could be seen bleeding near the hilum of the kidney, by suturing the incision in the cortex, and by gauze packing, but without materially lessening the flow of blood.

The child was rapidly becoming exhausted from the loss of blood, so he (Mr. Nash) decided to remove the kidney. The vessels and ureter were ligatured and the kidney removed as far from the ligatures as possible. Consequently most of the pelvis of the kidney was left behind. The stone removed consisted of uric acid and weighed 25 grains. It was a flat-shaped stone with a sharp edge. Recovery was retarded by some suppuration, but the ultimate result was good, the child passing about 20 ozs. of urine daily when he left the hospital.

This case illustrates the value of X-rays in the diagnosis of obscure renal calculus.

THE OUT-PATIENTS' ROOM.

FRENCH HOSPITAL AND DISPENSARY.

A Protracted Case of Localised Eczema.

By LOUIS VINTRAS, M.D., B.Sc.

AN Italian waiter, C. A., æt. 23, came to the out-patients' department on February 15th, 1905. He had a large patch of eczematous eruption on the back of his neck, extending transversely in a band about one inch and a half wide by about four inches long. The patch presented a rough surface, with squamous crusts here and there, while the rest was red and weeping. The skin was much thickened, and the band presented an abrupt and well-defined margin. There was a good deal of irritation, which was increased, of course, by the friction of the collar, of which the patient's occupation necessitated the continued wearing. Two years previously, the patient had first noticed a diffused eruption in the same place, which came and went, but increasing in area with each return. About six months later he contracted syphilis, for which he underwent treatment privately. Sometime after contracting syphilis the eruption on his neck became aggravated, no longer disappeared at intervals, and gradually assumed the appearance it presented when he first came to the hospital. He had then followed no treatment of any kind for three or four months. Arsenic internally and soothing lotions soon diminished the irritability, the crusts disappeared, the surface became dry, and the redness diminished. For some time, however, there were periods of renewed activity, more especially at the margin, but these were evidently due to the fact that as soon as there was any amelioration the patient resumed his collar and neglected the treatment. This went on for some months, during which the local conditions further improved, but only gradually. The surface was healed, but the thickening of the skin showed no signs of diminishing. Dr. Vintras then put him on iodide of potassium and bark, and ordered inunctions night and morning with the following ointment: Ung. hydrarg nit., 1 drachm; ung. ac. boric, $\frac{1}{2}$ oz.; vaseline, ad 1 oz.

This was continued for some time without producing any marked effect. Internal remedies seemed to make no impression on the local condition, for a course of mercury likewise produced no satisfactory result. About five weeks ago Dr. Vintras substituted Resinol ointment for the one the patient had been using, and since then there has been a decided improvement, the colour of the part is much more natural and the thickening of the skin much diminished. Dr. Vintras pointed out that the patient was a strong, well-built man, who otherwise enjoyed excellent health. The case was interesting, he thought, as showing the density of the fibrous thickening of the skin produced by a simple but long neglected eczematous eruption and the difficulty with which it subsequently cleared up.

MERCY HOSPITAL, CORK.

Case of Extensive Dermatitis Following a small dose of Quinine.

Under the Care of Dr. J. O'CONNOR, M.A., M.D., M.R.C.P.I.

THE patient was a young woman, æt. 24. As she suffered from anæmia she had purchased two drachms of citrate of quinine and iron (containing 20 grains of quinine) four days previously. She had dissolved this in a half-pint of water, and had taken half the amount when seen. During the previous night she felt hot and restless, and felt her skin flushed and itching. When seen her face was flushed, with a bright eruption resembling the rash of scarlatina covering the forehead, cheeks and ears. The eruption, however, was distinctly raised. The arms and hands were thickly covered with a bright red rash in large raised patches resembling urticaria, except for their colour which was of a bright pink hue. The thighs and knees were similarly covered, the legs below the knees being only slightly affected, the lesions here being more discrete and somewhat resembling the rash of measles. The neck, the chest, and the scapular region were similarly affected, but the lower part of the back and the entire surface of the abdomen were quite free from the eruption. In all situations the edge of the rash was distinctly defined, and the raised borders were quite evident. The temperature was 98.8°, though the feel of the skin was suggestive of a higher degree of pyrexia. The drug was stopped, a calamine lotion containing a little liq. carb. deterg. ordered, and a saline purgative given. Next day the temperature was normal; the patient reported that she had spent rather a good night, the rash was much less noticeable and had faded in many places. On the second day the rash was quite gone, and the patient felt all right. She had never previously had a rash of any kind, and though she had often taken tincture of iron for anæmia she had never previously taken quinine. Though quinine rashes are not very uncommon, the intensity of the dermatitis in this case was, apparently, out of all proportion to the amount of the drug absorbed, only 10 grains of quinine having been taken altogether.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

CONSERVATIVE SURGERY OF TUBERCULOUS DISEASE OF THE JOINTS.—MR. MAYO COLLIER operated on two cases of tuberculous disease, one of the hip and the other of the elbow joint, illustrating the modern method of treatment of this affection. 1. Tuberculous disease of the hip-joint. The patient was a boy, æt. 5, the subject of advanced tuberculous disease of the left hip-joint. The history of the case extended over a period of two years. When æt. 3, the child complained of pain in the region of the left hip-joint, extending down the thigh and knee. Advice was obtained, and the boy was admitted into a metropolitan hospital, and treated apparently by fixation and extension. The boy, according to the mother, left the hospital seemingly cured. On attempting to use the limb, however, and to run about in the ordinary way, he used the limb cautiously and was never as free with it as with the opposite extremity. The history of the present illness dated some nine months ago. The child was confined to bed with swelling and pain of the outer aspect of the limb. Advice was again sought in the out-patient room of a hospital. The parents refused further indoor treatment. It appeared from the statement of the mother that the case was then allowed to take its own course, and was subjected only to unskilled treatment. On admission to the North-West London Hospital, the boy was pale, emaciated, and in an extremely reduced

condition. The limb was flexed, adducted, and somewhat rotated inwards, and the parts in the region of the joint were riddled with discharging sinuses. The examination of the lungs and abdominal viscera revealed no complications. The general condition of the child was not encouraging. Mr. Collier said that here he had to deal with a case of advanced tuberculous disease of the left hip-joint, where one of two courses was only possible to pursue—amputation at the hip-joint or ex-section with free drainage. Against the proposal for amputation was, in the first place, the severity of the operation and the maimed condition of the patient if recovery took place, offering no prospect of useful employment during existence in after life; against the alternative of removing the whole of the diseased tissues in and about the joint, and leaving Nature to do the best she could to re-form a more or less useful limb, was the fact that the patient was now already much exhausted by a long-continued suppuration and bad nutrition. Considering the age of the boy, Mr. Collier elected to adopt the latter course. The sinus at the anterior border of the tensor vaginae femoris was enlarged and the finger passed into a necrosed and carious hip-joint. The joint was found to be completely disorganised. The whole of the cartilage of the acetabulum was gone and replaced by an extensive carious surface; the head of the femur was necrosed; the sinuses in the gluteal and iliac regions communicated with the main cavity, and the fibrous and muscular tissues about the joint were considerably contracted. Mr. Collier curetted with a sharp spoon the acetabulum, and removed the head of the femur, curetted the various sinuses, and divided any tense bands of fascia which prevented the limb being brought into the normal position. The tracts of the sinuses and the acetabular cavity were injected with emulsion of iodoform, and packed with strips of cyanide gauze soaked in the same solution. The incisions into the bands of fascia had been made originally well away from the seat of the original trouble. The limb was put up in a single Thomas's splint, and orders were given for the patient to be fed on albuminous diet consisting chiefly of raw eggs and milk.

It is gratifying to record that the patient, after six weeks' retention in the hospital, has now completely convalesced, the wound has entirely healed, the child has regained flesh, the limb is in a fairly good position, and there is every prospect of health with a permanently useful limb.

Case 2.—Tuberculous Disease of the Elbow Joint.—The same surgeon operated on a case much resembling the preceding one, except that the disease had here attacked the elbow-joint instead of the hip-joint. In this case, the prognosis, Mr. Collier said, was even more unfavourable than in the preceding one. The child, a boy, *æt.* 7, had already been treated for disease of the knee-joint and for tuberculous glands in the neck, and had spent most of its short existence in the wards of various hospitals. The scars about the knee-joint were an eloquent testimony to the severity of the disease that had affected this region, and the scars in the neck were unmistakable signs that the glands in this situation had been extensively affected. The affection of the elbow had existed for some twelve months, and the parents, being apparently discouraged by the previous continued illnesses, had not up to this time sought for advice at any hospital. On admission, the general condition of the child, Mr. Collier pointed out, was not so bad as might have been expected. He was fairly nourished, and of good colour, and there were no complications of the internal organs; the left

elbow, however, was enormously swollen and deformed by several large granulating surfaces that presented discharging sinuses. The skin around these sinuses was much undermined and invaded by tuberculous deposit, leaving few areas of healthy tissue about the joint. Here, again, Mr. Collier said, two courses presented themselves—amputation or ex-section. The same arguments as applied in the previous case were here to be considered. The patient was evidently riddled with tubercle, but he had got the better of two previous affections and his present general condition was fairly hopeful. Mr. Collier decided to give the limb a chance by removing the whole of the diseased tissues, as he had done in the previous case, reserving amputation in case the course of convalescence was less speedy than was to be desired or in case of complications or extension of the disease in other directions. The sinus between the head of the radius and the olecranon process was slit up and the joint opened; the olecranon was removed, and the whole of the interior of the joint exposed. Every part of diseased tissue that was found was removed with scissors and forceps and the sinuses curetted; the joint was packed with cyanide gauze and iodoform emulsion, and put up on a splint in a semi-flexed position. Here, again, orders were given for the patient to be dieted with albuminous food consisting mostly of raw eggs and milk, and the boy has made most satisfactory progress. The parts a month after operation were almost healed, the general condition had much improved, and there was every prospect of a sound and useful limb. Mr. Collier said that the procedure he had adopted in these two cases was much in advance of the surgery of tuberculous disease of these joints when he was a house-surgeon. The best that could then be hoped for, but which was seldom attained, was a stiff, useless, and deformed joint, and a shortened limb; more often, after months of the patient's confinement to bed, return of the disease took place in the excised limb, and amputation was resorted to when it was too late.

X-Rays at Cambridge.

At Gonville and Caius College the triennial Thruston prize of £54, open to a member of the college of not more than fifteen years' standing who has published in the course of the preceding three years the best original investigation in physiology, pathology, or practical medicine has been awarded to W. S. Perrin, B.A., research student of the college. At the invitation of the Regius Professor of Physic and the Professors of the New Medical Schools in Cambridge, recently, a large audience heard a lecture by Dr. Hugh Walsham on the use of the X-rays in diagnosis. The lecture was illustrated by numerous lantern slides prepared from skiagrams taken by Dr. Walsham. The latter half of the lecture was devoted to a demonstration and description of the most recent forms of X-ray apparatus. Dr. Walsham drew attention to the efficient and powerful X-ray installation he was using to demonstrate the various points. This apparatus had been presented to the committee for the study of special diseases by Dr. R. C. Brown, of Preston, Lancashire, and had been supplied by Watson and Sons, of London. Professor Allbutt, in proposing a vote of thanks, said they were deeply indebted to Dr. Brown for the extremely valuable and costly apparatus he had presented to the committee. Professor Woodhead, in seconding the vote of thanks, wished to say how grateful they felt to Dr. Walsham for coming to give the work of the Committee for the Investigation of Special Diseases, which had been organised by Mr. Strangeways, the Huddersfield Lecturer in Special Pathology, a good send off. This committee, having undertaken the study of rheumatoid arthritis, soon found that X-ray photography was essential.

TRANSACTIONS OF SOCIETIES.

SOCIETY FOR THE STUDY OF
DISEASE IN CHILDREN.

MEETING HELD FEBRUARY 16TH, 1906.

Mr. TUBBY, M.R.C.S., in the Chair.

Mr. HOWELL EVANS showed three cases: (1) Meningocele occipitalis; (2) Meningocele lumbosacralis; (3) Thyroglossal appendage; and these were illustrated by a lantern demonstration. He remarked that it is stated that the most frequent cause of spina bifida is the non-union of the laminae of a vertebra or vertebrae. This he did not consider to be a fact, but that the interposition of the membranes prevents the normal union of these osseous centres. He believed the cause of the formation of these protrusion cysts to be due to the toxicity of definite chemical bodies of primary maternal origin, these diffusible poisons transferred to the embryo stimulate certain epithelial or secreting surfaces with consequent increase of secretion.

Dr. F. J. POYNTON read a paper on two cases of "Jaundice in Children." Persistent jaundice in infancy was such a dangerous symptom, that the two cases which had come to his notice in the last two years were, he thought, of practical interest. This first case was a female infant, *æt.* 3 months. She was then distinctly jaundiced, and had been so since birth. The conjunctival mucous membranes and skin were yellow, the motions as a rule were undigested and white, the urine very dark. In fact, there was well-marked obstructive jaundice, which had lasted from birth. The liver was large, but not tender or unusually hard, the spleen was not felt, there were no hæmorrhages and the umbilicus was healthy. The second case occurred in a boy, *æt.* 4 weeks, and the first child. No cause at all was forthcoming for the jaundice, which had appeared upon the third day and was found to have persisted.

Dr. E. CECIL WILLIAMS contributed some notes on a case of "Splenomegaly Biliary Cirrhosis" in a boy, *æt.* 6½, and regretted it was impossible for him to show the Society his patient, but hoped the photographs he exhibited would convey some idea of the hepatic and splenic enlargement. He remarked that there was a doubtful history of paternal syphilis. Three years ago the child was jaundiced and said to have an enlarged liver. Abdomen, much distended; girth, 26 ins.; enlarged veins over surface, liver dullness extending from the fifth rib to the level of the umbilicus, where its free edge could be felt; left lobe could also be felt below the ensiform cartilage; spleen, much enlarged, extending from the eighth rib to within a couple of fingers' breadth of the iliac crest in the axillary line. That this was an example of the juvenile type of splenomegaly biliary cirrhosis, described by Gilbert and Fournier, seemed to him to be fairly certain. Clubbing of fingers and toes is a much more constant symptom in this form than in the adult type.

Dr. F. LANGMEAD showed three specimens of "Tuberculous Ulceration of the Stomach." *Case I.*: Mary C., *æt.* 8 months, was admitted to hospital for whooping cough; developed signs of pulmonary consolidation, and died two months after admission. At the *post-mortem*, general tuberculosis was found. The stomach was not dilated, but on its anterior wall were six shot-like submucous tubercles, each capped by a tiny ulcer, and two more were situated on the greater curvature. Their distribution was *via* the arteries, and on holding the specimen up to the light when it was first removed each tubercle could be seen perched upon an arterial twig. *Case II.*: Stephen B., *æt.* 1 year and 11 months, was admitted for whooping-cough and bronchitis, and died a few weeks later. *Post-mortem*:

At the middle of the anterior wall of the stomach about half-way between the cardia and pylorus, was a small tuberculous ulcer stellate in appearance, and surrounded by a slightly raised and rolled edge. *Case III.*: William T., *æt.* 7 months, was admitted collapsed, with a history of five months' "croupy cough" and wasting. *Post-mortem*: Near the greater curvature of the stomach, and midway between the cardia and pylorus, were two small ulcers with flat, slightly raised edges, the larger measuring only 4mm. in its greatest diameter, and being plainly situated on a vessel. The other, which was slightly smaller, was about half an inch distant. The peritoneal surface was unaffected.

Mr. W. GIFFORD NASH showed a case of "Symmetrical Alopecia Areata Neurotica," accompanied by a bulbous eruption on the face, in a girl, *æt.* 14, who was seen on November 13th, 1902, suffering from an eruption on the face and loss of hair. The history was that on November 7th, a lock of hair along the course of the right supra-orbital nerve fell out and on November 11th, blister-like spots began to appear on the face. Two years previously she had suffered from similar spots on her face and hands. These had occurred over a period of some months and had left brown stains. As already stated, the first patch of hair to fall out was along the course of the right supra-orbital nerve. Ten days later a similar bald patch suddenly appeared on the left side. The symmetrical distribution is well shown in the photographs. This affection is classed by Crocker under alopecia areata neurotica var: localis.

Mr. W. GIFFORD showed two cases of "Renal Calculus" in children under ten. These will be found on page 253.

Dr. A. ERNEST JONES showed a case of "Parenchymatous Goitre" in a girl, *æt.* 6.

Dr. GEORGE CARPENTER showed a case of "Scurvy" in an infant, *æt.* 10 months, slightly rickety, a tripe anæmic, and with hæmorrhagic gingivitis, subperiosteal hæmorrhage of the left tibia. The urine contained albumin and blood casts, but was free from other casts. Been fed on patent foods.

The following members took part in the discussion of the papers and cases:—Dr. Chapman, Mr. Tubby, Mr. Pernet, Dr. Frederick Taylor, Mr. Drew, Dr. Fisher, Dr. Milner Burgess, Dr. Porter Parkinson, and Dr. Sutherland.

ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE BELFAST MEDICAL INSTITUTE
ON MARCH 1ST, 1906.

Dr. J. R. DAVISON, Vice-President, in the Chair.

Dr. J. SINGLETON DARLING showed a patient from whom he had removed the inferior maxilla for a sarcoma involving that bone. The treatment of the resulting deformity was discussed by Drs. A. B. Mitchell and Howard Stevenson.

Dr. FIELDEN read a note on the
SOLAR REFLEX

occurring in abdominal operations. In giving anaesthetics he had often noticed reflex phenomena in operations on the stomach and kidneys specially, and these might be so severe as to necessitate an entire alteration of the plan of operation. Adhesions of the viscera undoubtedly made these symptoms more likely to appear, traction on the adhesions being the immediate cause. The breathing became shallow through a complicated reflex which was not certainly known, and cardio-inhibitory symptoms appeared as a direct result of stimulation of the vagus. The depth of the anaesthesia in no way modifies these reflex symptoms, but if they appear when chloroform is being used a

change to ether or A.C.E. mixture may be beneficial. They are more often seen in operations on the right kidney than on the left, owing to the greater liability to traction. They do not commonly appear in operations on the intestines.

Dr. THOMAS HOUSTON AND Dr. J. C. RANKIN read a paper on the methods and results of giving

Therapeutic Inoculations in Staphylococcal and Tuberculous Lesions.

Dr. Houston, who read the first part of the paper, referred to Dr. A. E. Wright's methods as forming the basis for a system of rational therapeutics such as we have never had in dealing with these affections. After a brief account of the method of determining the opsonic index of the blood, he enunciated the conclusions that in many affections opsonines exist in the serum; that opsonine is thermolabile, *i.e.*, destroyed by heat, and that the serum is the active agent in promoting phagocytosis. Various experiments were then described by means of diagrams on the lantern screen. In the first it was shown that with a given quantity of serum, washed corpuscles, and emulsion of staphylococci digested for a given time, 218 cocci were found in 100 cells, whereas when the experiment was repeated exactly, only that the serum was heated first, only 28 cocci were found in 100 cells, showing the injury done to the serum by heat. Bullock's experiments proved that opsonine is a new body, and apparently specific for each micro-organism, hard though it is to accept this.

After these preliminary observations, Dr. Houston said that he proposed to deal with lesions due to the staphylococcus, leaving it to Dr. Rankin to deal with tuberculous lesions. The first question they had set themselves to determine was whether their own opsonic power remained constant at different periods of the day, and from day to day, and they found that it did remain so. Another experiment showed them that any staphylococcus might be used for inoculations, and that it was not necessary to prepare a fresh culture from each patient treated. The method of preparing the emulsion of the staphylococcus was then described; the vaccine is a growth of the organism sterilised by heating to 60 for an hour, and tested by planting out for a night to be sure that all cocci are killed. The beautiful and ingenious method of standardising the emulsion, due to Dr. Wright, was described. An equal quantity of blood and emulsion are taken, diluted with saline and stained, and the relative numbers of corpuscles and cocci counted. Then since the number of corpuscles in a cubic millimetre is known, the number of cocci is easily estimated. A number of cases of lesions with low opsonic indices were described by Dr. Houston, many being boils due to septic poisoning. The dose of vaccine given was in most cases from one to five million staphylococci. If the vaccine was good, there should be no suppuration afterwards. The general effects of the inoculations were (1) a negative phase, with lowered resistance to infection; and (2) a higher resistance, gradually growing less, but still in many cases ending higher than it began. The negative phase is a function of the dose, and varies in different patients; it may even last for several months. Of the many cases described it may be said that those of furunculosis were generally cured, while those of acne were improved, but only one was cured. Dr. Rankin dealt with inoculations for tuberculous lesions. There was much more difficulty in getting a uniform emulsion of the tubercle bacillus than of the staphylococcus. The cases described included fifteen cases of lupus, five cystitis, five adenitis, four tuberculous peritonitis, and two phthisis. On the whole, the results were very encouraging, though in these chronic cases a long time is needed to judge well of results. The tuberculous peritonitis cases were specially successful, the immediate change under treatment being very marked. All the cystitis cases also improved, and put on weight steadily.

NORTH-EAST LONDON CLINICAL SOCIETY.

MEETING HELD MARCH 1ST, 1906.

Dr. C. E. HUTT, President, in the Chair.

The following cases and specimens were exhibited:—

Dr. R. MURRAY LESLIE showed (1) a man, *æt.* 60, with a hard, infiltrated swelling in the left supra-clavicular region of many months' duration. The surface over it was oedematous. He complained of pain extending down the left arm, but there was no difficulty in breathing. There was a history of syphilis and there were some old pigmented scars on the legs.

Mr. H. W. CARSON considered that it was a gummatous condition breaking down, the trouble probably originating at the sternal end of the left clavicle.

(2) Three female patients with Myxœdema, undergoing treatment, and presenting varying degrees of improvement. It was noteworthy that the one who had reacted most quickly to the treatment had been taking the raw thyroid gland obtained freshly from the butcher's every day. One patient had a magnificent crop of hair upon the scalp, but none in the axilla. All showed the characteristic, parchment-like condition of the skin upon the backs of the hands.

Dr. G. P. CHAPPEL showed (1) a boy, *æt.* 6, with Congenital Heart Disease; (2) a boy, *æt.* 10, a congenital imbecile, affected with Fibroid Phthisis. A persistent cough had been present for a long time, and when first seen the right lung was full of crepitations. The cardiac impulse was felt in the right nipple-line. (3) A man, *æt.* 30, a bootmaker, with Malignant Disease of the Lung. The whole of the right chest was dull, and the voice-sounds and breath-sounds obliterated. He had lost four stone in weight during the last year. The X-rays showed that the right side of the diaphragm was practically fixed and also a deep shadow occupying the lower part of the right chest. These appearances were quite consistent with the presence of malignant disease.

Dr. LESLIE thought that there was very little fluid present as the cardiac impulse was hardly displaced at all. He considered that the condition was probably one of sarcoma and that the prognosis was very grave.

(4) An old lady, *æt.* 65, with ascites and displacement of the heart to the left. She had had paracentesis performed, when nine pints of fluid were withdrawn. Several nodules were then felt in the abdomen, and the exhibitor was inclined to the view that it was a case of primary carcinoma affecting some portion of the intestinal tract. The liver was also enlarged, but there had been no jaundice.

Dr. ERNEST CURTIS showed a little girl of nine who had had an injury to her foot seven weeks ago, and since then had been unable to put the foot to the ground on account of pain. An examination with the X-rays, undertaken by Dr. Higham Cooper, revealed an indistinctness at the lower end of the tibia.

Mr. CARSON and Dr. COOPER considered that the radioscopic appearance together with the clinical aspect of the case left little doubt that the condition was one of tuberculous disease affecting the os calcis, and possibly the adjacent portion of the astragalus and tibia.

Mr. CARSON exhibited (1) a child, *æt.* 2, with a peculiar swelling in the left side of the neck, resembling enlarged glands, but in places distinct collections of fluid could be made out. He was inclined to the view that the tumour was a Cystic Hygroma. (2) A specimen of an appendix containing three thread-worms which he had removed.

In reply to Dr. J. HUNT, who inquired if the presence of the parasites was merely accidental or whether the worms bore any causal relationship to appendicitis, the exhibitor referred to a paper which he had recently read before the Clinical Society of London upon the subject. He had been able to collect fifteen cases in all of appendicitis associated with the *Oxyuris*.

vermicularis. The most noticeable feature of these cases was the severity of the subjective symptoms as compared with the objective signs of disease. In one case the pain was so intense that a diagnosis of pyosalpinx was seriously entertained before the abdomen was opened! (3) A portion of the pyloric end of the stomach showing a large perforation in a case of gastric ulcer. No operation was undertaken, as the patient was moribund on admission to hospital. (4) A Cysto-Sarcoma of the Testicle which had been slowly growing for six weeks, and which, clinically, resembled a hæmatocele.

Dr. G. BASIL PRICE showed specimens of enlarged lymphatic glands weighing 18 ozs., from the axilla of a patient who had died from lympho-sarcoma, together with a portion of the stomach, ileum, and spleen, affected with secondary deposits. The latter organ weighed 3½ lbs.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 2ND, 1906.

Mr. L. A. BIDWELL, F.R.C.S., presiding.

Dr. J. A. COUTTS read a paper on
SOME POINTS IN INFANTILE SCURVY.

The paper was based on some cases recently under the care of the author, in one of which extensive hæmorrhage occurred under the periosteum of the femur, the lower epiphysis of the same bone being separated. Although the usual treatment of such cases, namely, milk feeding and the administration of lemon juice was adopted, the case did not rapidly clear up in the usual way, and new bone was deposited under the periosteum which had been raised off the shaft of the bone, so that egg-shell cracking was clearly to be felt. An incision was then made into the swelling and some of the clot turned out, but the child did not recover. A similar case was then described in which no operation was done. It was subsequently found that the reason why the cases had not rapidly recovered under treatment was that the dairy company which supplied the institution in which the infants were under treatment had, unknown to the authorities, been supplying Pasteurised milk instead of ordinary cow's milk; when this was rectified the second child recovered. The paper was illustrated by the specimen obtained from the first case and skiagrams showing deposit of new bone under the periosteum in the second.

A discussion followed in which the President, Dr. Arthur Saunders, Dr. Fry, Dr. Joll, and Dr. Muir took part.

Dr. E. FURNISS POTTER then read a paper entitled
REFLECTIONS ON THE TREATMENT OF CHRONIC OTORRHEA.

The author pointed out that much attention had been turned to this subject recently, but although he thought that the profession generally were alive to the importance of the subject the public required a good deal more education in the matter. He then detailed the measures that were advised for the routine treatment of a chronic aural discharge by means of injections, drops, and the like, and pointed out that the time necessary, and the frequent visits which would be required to the medical adviser made it impossible, in a very large number of cases, for this form of treatment to be efficiently carried out. On reflection this had led the author to think that the much more frequent adoption of the radical mastoid, or complete post-aural operation, would be a great benefit to those who were the subjects of a running ear. This procedure was safe, and offered an almost certain prospect, in properly chosen cases, of curing the discharge in a reasonable time, and so freeing the patient from a trouble which was a constant menace to life. An interesting discussion followed in which Mr. Bidwell, Dr. J. B. Ball, Mr. Richard Lake, and Mr. Paton, took part, Mr. Lake showing by the lantern a number of

instructive pictures illustrating the complete mastoid operation. Dr. POTTER replied, and the meeting then adjourned.

CORK MEDICAL AND SURGICAL SOCIETY.

MEETING HELD ON WEDNESDAY, FEBRUARY 14TH, 1906.

The President, Dr. R. P. CROSSIE, in the Chair.

CASE OF CONCURRENT ACUTE RHEUMATISM AND ACUTE CHOREA, COMPLICATED BY CEREBRO-SPINAL MENINGITIS.

Dr. O'SULLIVAN showed a girl, æt. 10, admitted to the South Infirmary in a highly feverish condition, with well marked choreic movements. These were so severe as to render alimentation by the mouth impossible, so rectal feeding was begun and continued for the lengthened period of twenty-five days. To make matters worse, two big, unhealthy-looking bed-sores were present. Auscultation revealed the presence of murmurs at all the orifices, and, in fact, a condition of pancarditis prevailed. About a week after admission, retraction of the head was noticed, together with convergent strabismus of the right eye. Albumin appeared in the urine, and the joints were so relaxed that dislocation of the sternal end of the right clavicle occurred. The treatment consisted in counter-irritation by fly blisters over the second, third, fourth, and fifth intercostal spaces. Alkalis and aspirin to combat the rheumatic poison, and bromide of soda to relieve the meningeal hyperæmia, whilst strychnine was given hypodermically for the grave asthenia. The patient made a good recovery.

Dr. O'SULLIVAN remarked on the rare occurrence of such a case, and invited discussion as to the etiological factor in the complicating meningitis.

Dr. MOORE thought that the meningitis was due to the organism of rheumatism.

THE "FANGO" TREATMENT.

Dr. A. A. HUDSON read some notes on "Fango di Battaglia," giving an interesting account of its origin, chemical composition, the technique of its application, and the indications for its use. He said that not only was it invaluable in arthritic cases, but it was beneficial in anæmia, chlorosis, scrofula, eczema, psoriasis, &c. He read clinical notes of cases, Continental and English, and some that came under his own care, treated with brilliant results.

Dr. P. G. LEE then gave a paper on
THE PREPARATION OF ANTI-TOXINS,
illustrated by lantern slides showing the various steps and apparatus used.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD. FRANCE.

Paris, March 3rd, 1906.

OZENA.

Two principal symptoms characterize ozena—
increase in the nasal secretions, fætidity.

The secretions are increased; the patient uses several handkerchiefs daily and the flow is abundant, and of yellowish green colour. Sometimes it is dry in the form of crusts, which the patient expels at one effort, but which are reproduced continually.

The odour of the secretions is repulsive, and somewhat like the fætid smell of the sweat of certain feet. This odour becomes so intolerable that the patient is excluded from the school or the workshop.

The external aspect of the nose presents no characteristic deformity, but the examination of the cavities reveal a considerable enlargement of the nostrils, through which the posterior wall of the pharynx can be seen. The walls of the nasal cavities are covered with greenish mucus or with crusts. If they are

removed, the subjacent mucous membrane will be found smooth, brilliant, but without ulceration.

Localised at the beginning in the nares, the lesions extend rapidly to the pharynx, and even in some cases to the larynx and trachea, creating a special form known under the name of laryngo-tracheal ozena.

From a subjective point of view, the malady scarcely affects the general economy. The patient is unaware of his infirmity, but sooner or later the affection finishes by abolishing the sense of smell.

The complications observed in ozena are very few. The ear is hardly ever affected in ozena, contrary to what happens in acute rhinitis. On the other hand the eye is frequently the seat of lesions such as sacro-cystitis, conjunctivitis, ulcers of the cornea, keratitis.

Moure has described the following forms of ozena:—
Adenoid. Described by Grünwald and due to the presence of vegetations. This form is rare, but its existence is beyond doubt.

Necrosis of the ethmoid bones. It is natural to suppose that a lesion of these bones should give rise to ozena.

The purulent form is very frequent in children. At the beginning of the affection, the mucous membrane is swollen and painful, but later atrophy sets in in spite of every treatment.

The atrophic form of ozena is that generally observed. The nares are enlarged, the mucous membrane and the subjacent bones become atrophied, while the decomposition of the secretions produces the fetidity of the breath.

Ozena, insidious at the outset, constantly progresses, and once firmly established, atrophy develops with more or less rapidity and yields to no treatment.

Researches have been made for a specific microbe of ozena, and Løwenberg, and more recently Perez, described micro-organisms which they considered as the responsible agents of the malady.

On the other hand, ozena is very frequently hereditary, and appears to be transmitted more generally from mother to daughter. Syphilis, scrofula, lymphatism, constitute favourable grounds for the development of the malady, which is observed generally between the ages of eight and fifteen.

Treatment.—Ozena is an infirmity, and if the treatment cannot produce a radical cure, it can improve the symptoms. It consists in irrigations, ointments, powders, and medicated plugging.

The first thing to do is to remove the crusts by a plug of absorbent wool moistened with glycerine and phenic acid (1-15). Then abundant irrigations of the nares (one or two quarts) twice a day with some antiseptic solution: Salt water, 1 per cent.; phenosalyle, 1—1,000; resorcine, 1—400; thymol, 1—1,000; borax, chloral, &c.

After each irrigation, pulverisation of the cavities should be made with:—

Menthol, 15 grs.;
Eucalyptol, 2 grs.;
Vaseline oil, 2 oz.

Another method is as follows: Each day an irrigation of saline solution, at the end of a fortnight every two days, and, finally, twice a week, according to the need. Massage of the nasal mucous membrane by means of a plug of cotton-wool steeped in phenicated glycerine (1—15) should follow the irrigation, and the parts finally touched with a solution of iodine and glycerine (1—10) or chloride of zinc (1—60).

This treatment should be continued months and years. As general treatment, iron, arsenic, cod liver oil, &c., will be prescribed according to indications.

As local treatment, the following has also been recommended:—

Collargol, 8;
Sugar of milk, 2½ drachms.

To be blown into the nose twice a day after antiseptic irrigation. Or:—

Refined petroleum, 1 oz.;
Nitrate of strychnine, ¼ gr.;
Oil of eucalyptus, ten drops.

Paint the nares after irrigation.

GERMANY.

Berlin, March 3rd, 1906.

AMONG some interesting cases shown at the meeting of Charitée Physicians, Hr. Lesser introduced one of (a) a "self-inflicted skin wound" in a hysterical patient, æt. 16. She had numerous deep symmetrical cauterizations of the face from applying fuming nitric acid. She had disfigured herself in the same way on three previous occasions. In cases of "spontaneous" gangrene the condition was sometimes brought about in a similar manner. (b) A child, æt. 3, with a septic pemphigus-like rash that ran a febrile course, and had developed after removing the scab from a vaccination spot. In a discussion that took place, Hr. Henneberg remarked that the first patient was weak-minded and that she suffered from hereditary taint, and that she had been led to produce the disfigurement by various motives.

Hr. Roscher showed (a) "Spirochætæ," a section removed from a papule on the mamma, the preparation being stained after Levaditi's process. (b) Two cases of lues maligna with multiple genital and extragenital primary lesions. (c) A case of gangrenous herpes zoster in a case of syphilis, that affected the region of the first branch of the trigeminus, and had led to neuro-paralytic keratitis.

Hr. Brüning showed two "apes with primary syphilis of the eyelids." The course for such primary effect, were: a period of incubation from three to four weeks, transmissibility, immunity, microscopical appearances, and the discovery of spirochæta pallida.

Hr. Grumme showed (a) a case of syphilitic meningomyelitis in which the symptoms (disturbance of reflexes, anæsthesia, and serpiginous syphilides) had been improved by antisymphilitic treatment. (b) A case of tertiary syphilis with ulcers on the buttocks and legs, which had led to elephantiasis thickening.

Hr. Henck showed a case of congenital syphilis which, in addition to the usual symptoms, had developed arthritic changes on both hands.

At the meeting of the 18th ult, Herren v. Legden and Blumenthal described a case of

ACUTE YELLOW ATROPHY OF THE LIVER.

The case was that of a woman, æt. 27, in addition to the jaundice, which was very deep, there was mental disturbance, and, towards the end, coma. No trypsin was present in the urine. The autopsy confirmed the diagnosis of acute yellow atrophy of the liver. The first question was as to whether the tissue disturbances present were due to an increased production of amines acids or to a specific disturbance of the power of assimilation for those products. It was further striking why there was no disturbance of the power of assimilation for other amine acids than leucine and tyrosine. In the normal liver within the cells there was a ferment that split off these bodies. In acute yellow atrophy of the liver they were set free by the great disintegration. Along with this there was also a diminished power of assimilation. The question of autolysis was inquired into. No ferment acting upon another organ albumen was found, nor glycogen, nor sugar.

Hr. Lazarus spoke on

BIER'S LUMBAR ANÆSTHESIA IN MEDICINE.

It played a part also in internal medicine as, for instance, in the crises of locomotor ataxy, in compression myelitis, myoclonus, spastic spinal paralysis, in painful contractions in remobilising, and in the operation for stretching the sciatic nerve. In this, sensation was frequently paralysed, "dissoziert" as in syringomyelia. Other methods of anæsthesia had been sought for on account of the headache and the vomiting, often lasting for days, that accompanied it; over the peripheral nerves compression, cold, and Schleich's infiltration came under consideration. The speaker had now studied the action of change of the molecular concentration of the spinal fluid in 64 rabbits. He found that lowering of it by injection of distilled water caused pain, whilst a 0.2 per cent., a 0.75 per cent., and a 0.92 per cent. solution of sodium chloride were quite indifferent. Injection of highly concentrated

chloride of sodium solution caused the death of the animals with convulsions, a 7 to 8 per cent., on the contrary, caused anaesthesia and paralysis. Isosmotic solution of bromide of potassium and magnesium had the same effect. Whether these effects were produced by diffusion or by osmotic difference of tension was questionable. Histologically, oedema was found with this paralysis. The anaesthetic action of solution of sulphate of magnesia was shown, also on the exposed motor cerebral centres.

Hr. Bosse reported on experiments made in the Surgical Klinik of the Charité on the same subject. Alypin and stovain were employed in 55 cases. The time required for the onset of the anaesthesia varied very much, and its extent was irregular. In eight cases the results were nil, and headache, sickness, thoracic oppression, incontinence, and slowing of the pulse were observed repeatedly. In one of the cases ecchymosis of the pleura was seen. For these reasons, the speaker observed, these methods of lumbar anaesthesia were not a perfect substitute for chloroform.

Herren. Michaelis and Fleischmann spoke on

ANTI-LIVER SERUM.

They said that antibodies were readily demonstrable so long as a visible reaction was obtainable; but when this was not so their demonstration was difficult. Through experiments made by themselves they had discovered a new way of proving their presence (the method of complementary disappearance). Complementary disappearance could also be observed in the living animal, but in the human subject no such phenomenon had been demonstrable.

AUSTRIA.

Vienna, March 2nd, 1906.

CRETINISM IN DOGS.

At the "Gesellschaft," Wagner presented a dog with all the symptoms of endemic cretinism. The dog came from Weiskirchen, in Styria. The head was small, with thick bones and hypertrophy of the soft structures, more particularly those of the face. The legs were heavy, thick, and short, and moved with an awkward apathetic gait.

Wagner thought this an important subject for investigation among animals, as it may account in many cases for the endemic production of this disease in the human species. Several years ago, in conjunction with Schlagenhauser, he commenced to investigate this subject, as he suspected such an origin, but their labours ended in disappointment at that time. Since then many obscure suspicions have been confirmed, and this pathological anomaly in dogs may lead to a revelation in the origin of cretinism.

Pupovac remarked that he was rather sceptical about the cretinism of dogs producing endemic cretinism in the human race. He recollected a gentleman in Admont who had a dog that gave birth to five young, three of which were cretinic, the other two feeble. All were fed on thyroid gland, with the result that the three cretinic became strong and healthy, but the other two which were at first supposed to be only weak, and not affected, died.

Alexander gave a brief description of the anatomical defects in the hearing of the cretin animal and particularly dogs. The defective perception of high tones, while moderate and deep tones can be heard, proclaims a lesion of the internal apparatus, probably the labyrinth, or acoustic nerve, either extra- or intracerebral. After localising this lesion he confined himself to the division of the pathological changes met with in the human subject. These, he thought, might be divided into three classes or groups according to their characteristics. The first group comprehended tubal catarrh, which affected the echo or resonance of sound. This morbid change in hearing is often produced by hypertrophy of lymphoid tissue of the pharynx in the form of adenoid vegetations. This group of changes is greatly improved by a course of thyroid treatment—the catarrh disappearing and the hearing more acute.

The second group is composed of the cretinic deaf and dumb, resembling the congenital form of deafness, having no pathological centre in the anatomy marked out as the cause of deafness.

The third group includes cases not so severe as to prevent testing of the physical power of hearing, although this function is performed with difficulty. In cretins, this group recovers rapidly in hearing under the influence of the thyroid gland, just as the internal cases do. There is no doubt of the defective hearing in cretins, but the difficulty is intensified when we attempt to determine the degree, as the intelligence is low and no reliable data can be deduced from the tuning-fork test, therefore no exact diagnosis can be obtained in these cases.

Hammerschlag repeated the results of Eberth's research on calves which were also affected by cretinism. He also quoted Habermann's conclusions that all cretins were defective in the perception of sound as recorded by his apparatus.

Wagner remarked that Eberth's and Habermann's cases were those of chondro-dystrophia, which in no way could be allied with cretinism, but was more probably a sort of micromyelia in the adult.

LYMPHANGIOMA IN LEFT GROIN.

Lieschner showed a patient, æt. 40, who for six years had a swelling in the left groin about the size of a walnut. It rapidly increased in size and finally a fistula formed that discharged a clear fluid. It was of a hard consistence, lying about the middle of Poupart's ligament, and having a knobby surface with a mushroom appearance. Below Poupart's ligament another tumour of a similar character and about the size of a man's fist formed, but soft in consistence as if cystic.

By pressure it could be reduced to half, while the upper became larger. When the upper was pressed the opposite effect was produced.

By pressing or coughing the tumour was enlarged, but no sign of hernia was perceived.

An operation was contra-indicated, as subsequent inflammation might supervene from the fistula present.

Payer's method for treating lymphangioma was adopted with excellent results. This consists in arrows of magnesium being inserted with an injection of iodoform glycerine.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH ROYAL ASYLUM.—The annual meeting of the Corporation was held on February 26th, when Dr. Clouston, the Physician superintendent, submitted his annual report. During the year 200 male, and 228 female patients were admitted, while there were discharged 130 males and 127 females. The average number of patients resident was 870. One of the most striking features of the admissions, from a medical point of view, was the large number—sixty-four—of cases of general paralysis, which was in excess of any previous year. Even more remarkable was the comparative increase of the disease in the female sex among the poor. When Dr. Clouston first came to the asylum as assistant physician in the early sixties it was most uncommon to have a woman admitted suffering from general paralysis; in 1872 there were no such admissions, and in 1874 only 3 cases. This year 38 women suffering from the disease were taken into the asylum. General paralysis was most frequent among the rate paid class, there being only 5 males and one female among the private patients. 18.6 per cent. of the rate-paid patients suffered from the disease, while among the private patients only 5 per cent. were so afflicted. For the first time the number of admissions of female general paralytics exceeded that of the men. This was a bad sign of the moral status and mode of life of the class from which these patients came, and was a sidelight of a very depressing character on our social life.

To show the enormous difference in the local distribution of the disease, he instanced Ireland, in which with a population of 4½ millions only 52 such cases were admitted to all the asylums. Great cities, vice, dissipation, and undue excitement, were the breeders of general paralysis. Dr. Clouston then alluded to Dr. Ford Robertson's work on

THE MICROBIC ORIGIN OF GENERAL PARALYSIS, to which the Morison lectures, of which an abstract has recently appeared in this journal, were this year devoted. He accepted as now proved this new theory of the etiology of the disease; the difficulties he had felt had been overcome by the convincing facts brought out by the investigations in the Laboratory of the Scottish asylums. The immediate cause of the disease was a microbe, acting specially on brains weakened by dissipation or poison. He did not expect the microbe theory to be at once accepted by the whole medical profession; before full confirmation was generally admitted Dr. Robertson's methods and research would have to be repeated. The cheering point in the investigations was that it pointed to the possibility of a method of cure being found.

ALCOHOL AND INSANITY.—Of the admissions 110, or 25 per cent., were due wholly or partly to excess of alcohol; in the men it was 30 per cent., in the women 22 per cent. This was an increase on the average of the past five years, and it was lamentable to note that the percentage in women had gone up from an average of 16.2 in the previous 5 years to 22 per cent. this year. The proportion of cases among private patients was only about half of that in the rate-paid class. Education and better social circumstances were accompanied by increased self-control in this respect, a fact which points to the best remedy for undue indulgence in alcohol. But our alcoholic insanity rate was still far too high among all classes. The latest researches on heredity tended to prove that the results of excess in drink did not end with our generation, but produced mental and physical degeneracy in the descendants. There was much room for the educator, the religionist and the legislator in this matter. The Medical Man and the physiologist were more and more compelled to warn people on the present and far reaching dangers of alcoholic excess. Old prejudices and custom should be counteracted by teaching the young to regard modern scientific knowledge as one of the great rules of life. The great bulk of recent cases of insanity were of the melancholic type—a reversal of the rule of twenty years ago. The great epidemic of influenza of 1889-90 and subsequent lesser epidemics, notably caused many deaths, and lowered the nerve tone of the community, and in consequence the melancholy phase of insanity throughout the country has become much more common than previously. The recovery rate for the year was 32 per cent. of the admissions, a low rate as compared with their average of 39.2. The death-rate was high—13.3 per cent. on the average number resident, and 9.2 per cent. on the total under treatment. The mortality was much higher (18.2 per cent.) among rate paid than among private patients (7 per cent.), which was accounted for by the large number of cases of general paralysis and organic brain disease among the former class. The average length of residence among rate-paid inmates was 5.8 years, and among private patients 10.3 years. Craig House still maintained its unbroken record of no consumption among its inmates, and that had been continued during the 11 years it had been open which was a unique fact in the history of mental hospitals. There was clear statistical proof that nowadays aged dotards and broken-down persons whose mental power was affected were sent to asylums in large numbers if they could be got on the rates, while the better off classes nursed such patients at home. This was the explanation of the apparent enormous increase of rate-paid insanity in recent years. Until the numbers of private patients, paid for out of their own means or by their relatives showed an increase in admissions to asylums—and since 1858 there had been no increase in the Scottish asylums—he could not believe that

there was any alarming increase of lunacy in the country. In concluding his report Dr. Clouston adverted to the question of treatment of early cases. The Royal Infirmary or Parish council should provide hospital accommodation for transient uncertifiable forms of mental disease as an important means of decreasing ultimately incurable insanity. While it was notoriously difficult to forecast the future course of health legislation, the trend of democracy was towards measures for the greatest good of the greatest number, irrespective of the feelings of the individual, and it was quite possible that mental diseases might become notifiable as one means of eliminating the unfit for marriage.

CARNEGIE TRUST AND THE PAYMENT OF CLASS FEES.—The fifth annual report of the Carnegie trustees is a more than usually interesting document. The part dealing with Clause A of the constitution, under which payments are made towards equipment and teaching, and original research, calls for no special remark, because by the system adopted some years ago of allocating definite sums to the universities for specified objects, payments being spread over a quinquennial period, all that is recorded is the gradual fulfilment of these objects, the construction of buildings, and the endowment of lectureships, etc. A number of grants have also been made for analogous purposes to various extra mural teaching bodies. The endowment of research has been carried on as in previous years, about £5,000 being spent on this object. During the year 36 investigators worked in the College of Physicians laboratory, which is now the property of the Trust. A volume of reports has been published and material for another is accumulating; besides this, many theses for the degree of M.D. have been based on the work in the laboratory, while the surgical fellowship was gained by one of the investigators. The section of the report dealing with the payment of class fees, however, contains much food for reflection. The fact is that if the present system is continued, funds will soon run short. The number of beneficiaries for the winter 1905-6 is 3,184, an increase of 109 over the previous year, while the fees paid during the year amounted to £47,853, distributed among the universities as follows:—St. Andrews, £3,483; Glasgow, £11,032; Aberdeen, £6,286; Edinburgh, £11,466. The amounts expended on class fees for the previous financial years 1902, 1903, 1904—£40,285, £44,104, £45,903—have steadily increased, not merely by the growing number of beneficiaries, but also by the rise of the average fees paid per beneficiary, this rise being due partly to the greater number of classes attended, and partly to three of the Universities having raised certain class fees. A year ago the committee formed the expectation that the limit of expenditure had been reached, but this anticipation has not been fulfilled, as the expenditure this year shows a rise of close on £2,000. An analysis of the relative increase of beneficiaries and average fees per beneficiary shows that the greater amount expended has been required from both these causes.

As the *Scotsman*, in an editorial puts it—"the fee fund may be said to be insolvent, because the universities have been too eager to use it for replenishing their purses. The cow has been cruelly milked." Making all allowance which the temptation of being able to draw on a fund vested in trustees, instead of the pockets of the students' parents, affords, it looks very like greed that Aberdeen should in five years have increased its average fee from £12 10s. to £16 15s., or nearly 33 per cent. It is quite notorious that many students avail themselves of the benefits of the Carnegie Funds whose parents are perfectly able to pay a very considerable part, at least, of the fees, and it has been no part of the plan of the trust to check this in any way. Indeed, the founder contemplated payment to any otherwise qualified student who applied, without restriction or curious inquiry. Possibly the publicity given to the state of matters may diminish the drain on the funds from this source, which is, of course, one direction in which the trustees may turn their eyes in trying to reduce their expenditure.

LETTERS TO THE EDITOR.

IS WRIGHT'S OPSONIC INDEX ESTABLISHED?

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With regard to Wright's opsonic index I venture to ask if it is not somewhat premature to term his complicated system a new era of therapeutics. That it is an attempted move in the right direction seems certain, but that it is a practical addition to our working methods I venture to doubt. The crux of the whole thing is to test the resistance of the blood, natural and acquired, to tubercle (and other) bacilli, and thereby to secure data for correct anti-bacterial dosage. The whole method is highly technical and can be carried out only at a prohibitive cost. Ten guineas is an ordinary charge for a single examination in private practice, and that has to be repeated indefinitely. In hospital practice so much time is required that a highly-paid pathologist and a well-equipped laboratory are indispensable. After all said and done do we gain anything that might not be learnt by simple clinical observation? I say emphatically we do not, and, moreover, the method is riddled with crude fallacies. The standard opsonic of normal blood, for instance, varies between .5 and 1.3; a fine standard, forsooth, for a system that aspires to finality in accurate estimation. I trust, sir, that the world of medicine will wait awhile before accepting Professor Wright's fascinating theories—or we shall find ourselves once more grasping at a Will-o'-the-Wisp.

I am, Sir, yours truly,
CUNCTATOR.

Balham.

ECLAMPSIA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of February 28th, Dr. A. Stookes is reported as having stated at a meeting of the Liverpool Medical Institution held on February 15th last, that "He wished to draw attention to a remarkable series of cases lately published by the Rotunda Hospital, where 71 cases of eclampsia were treated with a mortality of 1.69 per cent."

I regret that we cannot lay claim to results so satisfactory as this, and 1.69 should read 16.9 per cent.

I may, however add that my own statistics are a great deal better than the above.

I have attended in all 27 cases of eclampsia with 2 deaths, which gives a percentage of 3.7.

These fatalities will be described in my annual Report of the Hospital shortly to be published, and are both far removed from the type of eclampsia usually encountered.

I am, sir, yours truly,
E. HASTINGS TWEEDY,
Master Rotunda Hospital.

Rotunda Hospital, March 4th, 1906.

HOSPITAL PHYSICIANS, SURGEONS, AND THE PUBLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would be well that those who are interested in hospitals, and the public generally, should understand clearly how the services of the physicians and surgeons for hospital work are obtained.

The public may not take much, if any, interest in the education of medical students, and there are some who object to hospital patients being utilised in any way for that purpose. The question then must arise what return are you going to make for the important services of your physicians and surgeons? For if those services are gratuitous, it is only from the medical schools that any pecuniary profit can for certain be made.

If a physician or surgeon looks for a return from the reputation his hospital may give him, he may find that a special hospital is worth far more than a general one, and he would rather use it for special work and know-

ledge than for any profit from teaching. The education of students preparing for the practice of medicine is like that of many other arts in this country, in a bad state. Engineering is beginning to stir a little as there is more money invested in such work than in the arts of music, painting, and medicine. The time has come when the profession will have to make a stand, and there is not much doubt that if our hospitals are not going to be used for teaching, they will not get good professional help for nothing. Those who know anything of the work that William and John Hunter did as teachers; and what the results of their work were, and how men like Wm. Laurence, South, Travers, and others were trained to be great surgeons, they will, let us hope, not let the education of our students lapse into the anæmia that seems to have come over teaching generally in this country. The public will suffer for it sooner or later, and I hope that the influence of your journal will be brought to bear on this subject.

I am, sir, yours truly,
INQUIRER.

IRRIGATION OF THE NOSE IN RHINITIS IN CHILDREN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of this date, it is recommended by your Paris correspondent in the treatment of this affection, that an enema syringe be used in washing out the noses of children suffering from purulent rhinitis (p. 230). Your readers should know that such syringing of the nose has been condemned by almost all the great otologists who have written during the past quarter of a century. It is a very efficient means of setting up acute otitis media.

I am, Sir, yours truly,
February 28th, 1906. JOHN B. STORY.

HOSPITALS AND THE PUBLIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I saw in Thursday's *Daily Telegraph* a report of the meeting held at the Westminster Hospital when the question of the relation of the Medical School to a hospital was discussed.

It seems rather doubtful whether it is of any advantage to the physicians or surgeons of a hospital to have a school attached to their hospital, and certainly a "special" hospital may be of far greater advantage in the matter of reputation and practice.

Dr. Allchin's connection with the Westminster Hospital school I thought was severed some time ago, and this makes it difficult to understand the remarks he made at the meeting.

I am, sir, yours truly,
A HOSPITAL SURGEON.

OBITUARY.

ADAM WILKINSON, M.D.St.AND., F.R.C.S.Ed., M.R.C.S.Eng., J.P.

DR. ADAM WILKINSON died last week at Sheerness, at the age of seventy-four. He was professionally educated at Charing Cross Hospital, and qualified in 1867 as M.R.C.S. and L.R.C.P., Ed. He took the M.D. degree, of Brussels in 1883, and of St. Andrews in 1884, and the following year was elected a F.R.C.S. Edin. He was consulting physician to the Westminster Memorial Cottage Hospital at Shaftesbury, of which he was formerly medical officer, and he had been a member of the General Council of the University of St. Andrews.

EDWARD JOHN LONGTON, M.D. Edin.

WE regret to announce the death of Dr. Edward John Longton, formerly a well-known medical practitioner in South-West Lancashire, at Ulverston, at the age of seventy-six. He was born in 1829, and pursued his medical studies at King's College, London, and the University of Edinburgh, being admitted a

member of the Royal College of Surgeons, England, in 1852, and a L.S.A.Lond., and M.D. of Edinburgh in 1853. He was formerly honorary surgeon to the Southport Strangers' Charity. Dr. Longton was a magistrate for Lancashire and a Fellow of the Zoological Society.

WM. ROBINSON, M.R.C.S.ENG., OF HUDDERSFIELD.

We regret to record the death of one of the best-known men in this borough in the person of Mr. William Robinson, who was the doyen of the medical profession in Huddersfield, in the eighty-eighth year of his age. He entered the medical school at University College, London, where he was admitted a member of the Royal College of Surgeons of England in 1839. Returning to Huddersfield he became a house surgeon at Huddersfield Infirmary for a period, and then joined his father in private practice, remaining with him till he died in 1865. He was greatly esteemed by his professional brethren, one proof of which was given by his election as first president of the Huddersfield Medical Society.

THE DEATH OF DR. LOUIS DE WECKER.

It is a curious fact that scarcely any notice has been taken by the medical press of the death of Dr. de Wecker, of Paris, who passed away on January 24th last. De Wecker's name is not unworthy to rank beside those of Von Graefe, Bowman, Donders, and Desmarres. The following sympathetic little notice we extract from the current number of the *Ophthalmoscope*:—"The death is announced from Paris of Louis de Wecker, aged eighty-three years. Born at Frankfort-on-the-Main in 1832, de Wecker pursued his earlier medical studies at Wurzburg. He afterwards became Desmarres' assistant in Paris, and studied with v. Graefe in Berlin. In 1861 he obtained his Paris degree, and purchased from Deval the well-known clinic in the Rue Visconti. A few years later he attended Leon Gambetta, one of the most interesting statesmen who has ever flitted across the troubled stage of French politics. De Wecker removed an eye from his distinguished patient. In 1870, de Wecker left the Rue Visconti for the Rue de Cherche-Midi, where he established one of the largest and best-appointed eye clinics in Paris. He continued his devoted services during the darkest days of the siege of Paris, and was nominated surgeon to the national guard. De Wecker's name and fame are known in every part of the world where ophthalmology is practised. He was the author of "Traité des maladies des yeux" (1863), of "Traité des maladies du fond de l'œil" (1870), of "Thérapeutique oculaire" (1878), of "Chirurgie oculaire" (1879), and finally, in conjunction with Landolt, of that monument of patient research and prolonged labour the "Traité complet d'ophtalmologie" (1882-1885). He wrote numerous articles in the periodical press, especially upon such subjects as cataract extraction, iridectomy and jequirity. De Wecker introduced sclerotomy as a cure for glaucoma, and the operation of tattooing as a means of concealing leucomata and of improving sight in cases of the kind. His name will always be associated with his *pince-ciseaux* for the division of after-cataract, and with his double strabismus hook for advancement of the recti tendons. A master of ophthalmology has gone from us. May he rest in peace!"

J. R. KEALY, V.D.

We regret to announce that Dr. Robt. Kealy, V.D., of Ashley House, Gosport, died on Saturday evening. He caught a chill about ten days ago, and took to his bed on Wednesday last. He was attended by Dr. Lamplough.

Dr. Kealy was probably the best-known medical practitioner in Gosport, where he resided since 1849, and he was born at Ipswich on September 8th, 1830, and worked on the Board of Health in London at the time of the cholera epidemic in 1849. He was also vice-chairman of the Church Schools' Council of Alver-

stoke, and was president and lecturer of the Gosport and Alverstoke Literary Association. The deceased gentleman was for many years a hon. surgeon to the out-patients' department of the Royal Portsmouth and Gosport Hospital, and was always a kind, sympathetic, and clever physician. He was greatly respected by his fellow-townsmen, who will feel his loss keenly.

LITERARY NOTES.

DR. ARTHUR E. BODINGTON, of Winchester, has edited a reprint of his famous forebear's essay on "The Treatment and Cure of Pulmonary Consumption," which appeared in 1840, and foreshadowed the modern "open air" methods now so generally approved.

DR. T. N. KELYNACK has just issued a useful little work on "The Alcohol Problem in its Biological Aspect," which deals with the so-called temperance question on sound scientific lines likely to be of service to teachers and students.

SIR FREDERICK TREVES is a Dorset man, claiming fellowship with such distinguished Dorchester men as Hardy the novelist, and Barnes, the poet; and it is therefore particularly fitting that he should have undertaken the preparation of the volume on Dorset for the justly popular "Highways and Byways" series published by Messrs. Macmillan.

MILITARY men, litterateurs, and the clergy, by some indefinable force which we cannot attempt to explain, seem irresistibly attracted to the mysteries of medical quackery. A notable example is now conspicuous in the new editor of our immortal contemporary, *Punch*, for according to *The British Weekly* Mr. Owen Seaman is "treasurer of the Society which provides the 'Normyl' treatment for the cure of alcoholism and the drug habit." Surely this incongruous association of *Punch's* chief representative with a discredited piece of quackery might offer material for the welcome cartoonist, or at least a subject for discussion at the time-honoured dinners.

"A Guide to Diabetic Cookery" is before us. It is a concise and well-arranged handbook which will meet the needs of both practitioners and patients. In the management of diabetes detailed instructions are of paramount importance and within these pages will be found one hundred and fifty-one recipes affording a varied and attractive dietary. Formerly "diabetic foods" was an expression almost synonymous with "distasteful diets," but if the instructions afforded in this little manual are followed, the grievances of these long-suffering invalids will be in a great measure removed. The little work is published at a low price, which places it within the reach of the poorest patient, by Messrs. Callard and Co., of Regent Street, London, the well-known food specialists, a sufficient guarantee that every care has been taken in its preparation. To many a perplexed physician this collection of recipes will prove most helpful.

THE current (March) number of *The Ophthalmoscope*, edited by Mr. Sydney Stephenson, is devoted to the important practical subject of "cataract." Our enterprising contemporary has secured original articles from such masters of the subject as Sir Anderson Critchett, Major H. Herbert, Lieut.-Col. E. F. Drake-Brockman, Mr. Henry Power, and Mr. C. Devereux Marshall, to say nothing of less ambitious contributions from Dr. A. L. McMillan (Glasgow), and Dr. D. S. Sager (Brantford, Canada). *The Ophthalmoscope* contains, besides, classified abstracts of British and foreign work on many questions dealing with cataract—as, for example, operations, pathogeny, pathology, and complications after extraction. It is altogether an admirable number, reflecting credit upon those responsible for the management of the journal.

MEDICAL NEWS IN BRIEF.

Death from Ethyl-Chloride in Dentist's Chair.

WHILE under an anæsthetic at the surgery of Mr. Warburton Browne, dentist, of Charles Street, Mayfair, the Rev. William Henry Eley, aged sixty-seven years, Rector of Deene, Wansford, Northamptonshire, died. The inquest when held revealed that ethyl-chloride, which was administered to the patient, possessed unexpected dangers. Mr. Browne said that the rector had consulted him for several years. Two years ago Mr. Eley was placed under the influence of gas and oxygen, which he took well. On Tuesday he attended to have four teeth extracted, and the anæsthetic on this occasion was ethyl-chloride. The patient was one minute taking the anæsthetic, and the operation lasted one minute and a half. When the fourth tooth had been drawn, Mr. Eley became very pale, and died almost immediately, remedies which were promptly applied proving useless. Witness had seen ethyl-chloride given on about 200 occasions; it had been known for about three years. Dr. Alex. Browne, of Kentish Town (brother of the dentist), who administered the anæsthetic, said his experience of ethyl-chloride had been very favourable, and he had given it in one-third out of about 150 cases. It was liable, however, to give rise to a good deal of muscular rigidity at times, so that respiration might be suspended; but he did not know that it dangerously depressed the action of the heart. Before the operation he examined Mr. Eley, and realised that the arteries were rather thick and brittle. He did not examine the heart in great detail, because the patient, who was not at all nervous, seemed unwilling. He had never known a case of heart failure through the use of this new anæsthetic. After this case he had altered his opinion as to ethyl-chloride; apparently it was not as safe as his previous experience had led him to suppose. Dr. Robert S. Trevor, of St. George's Hospital, who made a *post-mortem* examination said death was due to syncope while Mr. Eley was suffering from fatty degeneration of the heart. The jury returned a verdict in accordance with the medical evidence, and absolved Messrs. Browne from all blame.

Malta Fever—Report of Special Commission.

THE Royal Society has issued a further report of the commission appointed by the Admiralty, the War Office, and the Civil Government of Malta, for the investigation of Mediterranean fever. In a previous report it was shown that goats in Malta are susceptible, this being demonstrated by the presence in their milk of the specific microbe, *Micrococcus melitensis*. It has also been determined that certain species of mosquitoes in Malta act as carriers of the microbe, while there is a strong probability that it is transferred by the insect from man himself. It appears that Malta fever can be acquired by the absorption of infected goats' milk from the alimentary canal, and that this mode of infection is largely responsible for the disease among the Maltese, who drink raw milk drawn at the doors of their houses. Drastic preventive measures are recommended.

St. Thomas's Hospital.

THE following House Officers have been appointed from yesterday (Tuesday), March 6:—*Casualty Officers*.—(Senior) G. R. Footner, M.B., B.C.Cantab., M.R.C.S.; (Junior) F. R. E. Wright, M.B.Lond., M.R.C.S., D.P.H. *Resident House Physicians*.—F. M. Bulley, M.R.C.S., L.R.C.P., M.A.Cantab.; R. C. Jewsbury, M.A., M.B., B.Ch.Oxon., M.R.C.S.; and W. O. Meek, M.B., B.S.Lond., M.R.C.S. (extension) C. St. A. Coles, M.R.C.S., L.R.C.P. (extension). *House Physicians to Out-Patients*.—M. A. Cassidy, M.A., M.B., B.C.Cantab., M.R.C.S.; H. S. Singleton, M.R.C.S., L.R.C.P. *Resident House Surgeons*.—H. T. Gray, B.A., B.C.Cantab., M.R.C.S.; A. W. Hooker, M.B., B.S.Lond., M.R.C.S.; J. H. Drew, M.B., B.S.Lond.,

M.R.C.S.; H. Falk, B.A., M.B., B.C.Cantab., M.R.C.S. *House Surgeons to Out-Patients*.—R. J. H. Cox, M.R.C.S., L.R.C.P.; F. S. Hewett, B.A. Cantab., M.R.C.S.; A. B. Howitt, B.A.Cantab., M.R.C.S., W. G. Howarth, M.A., M.B., B.C.Cantab., M.R.C.S. *Obstetric House Physicians*.—(Senior) R. E. Whitting, M.A., M.B., B.C.Cantab.; (Junior) S. R. Gibbs, M.R.C.S., L.R.C.P. *Ophthalmic House Surgeons*.—(Senior) C. R. B. Eyre, M.R.C.S., L.R.C.P.; (Junior) H. E. Gotelee, M.R.C.S., L.R.C.P. *Special Departments*.—(Throat) S. G. MacDonald, B.A.Cantab., M.R.C.S.; H. B. Whitehouse, M.R.C.S., L.R.C.P.; (Skin) W. O. Sankey, M.R.C.S., L.R.C.P.; A. N. Dickson, M.R.C.S., L.R.C.P. (Ear) R. N. Cunningham, B.A.Cantab., M.R.C.S.; A. L. Loughborough, M.R.C.S., L.R.C.P. *Children's Surgical*.—C. M. Page, M.R.C.S., L.R.C.P.; and S. G. MacDonald, B.A.Cantab., M.R.C.S. *Electrical (X-ray Dept.)*.—N. R. Cunningham, B.A.Cantab., M.R.C.S.

Metropolitan Hospital Sunday Fund.

A MEETING of the council of the Metropolitan Hospital Sunday Fund was held on the 2nd inst., at the Mansion House, the Lord Mayor presiding. Sir Edmund Hay Currie, the secretary, read the report of the Committee of Distribution on the increase of out-patients. They stated that on July 27th last a resolution was passed by them expressing the opinion that the serious increase in the number of out-patients (many of whom had trivial complaints) was detrimental to the welfare of the hospitals and patients, inasmuch as they were a burden to the funds and prevented the staffs from giving the necessary attention to serious cases. A copy of this resolution was forwarded to 80 hospitals having out-patient departments inviting the opinions of their committees on the question, and asking if they could suggest any remedy. The replies had been received, and the suggestions tabulated. The reports seemed to show that the number of general out-patients was decreasing, but the attendances at the special departments caused an increase in the actual figures. Suggestions had been made to the committee that, after the first visit, patients should not be allowed to attend a second time without a certificate from a medical man in the neighbourhood that the case was a proper one for treatment at a hospital. They could not see their way to agree to this proposition, but they were of opinion that if such cases could be referred to a private practitioner or to a self-supporting dispensary (provided sufficient of these could be established), nothing but good would result, especially if the dispensaries were attended, not by a few medical men in the district, but by the whole of the general practitioners in the immediate neighbourhood, such dispensaries to be affiliated to the nearer general hospitals. The committee recognised that the constituents of the fund had, for the first time, decided to make grants to "district nursing associations, employing fully-trained hospital nurses" (there were about 300 of them engaged throughout the metropolitan area), and as these nurses worked only under the direction of local medical men, it was felt that some sort of affiliation should be made, and that casualty patients might be recommended to apply to the superintendents of these associations after receiving "first aid" at the hospital, thus coming under the professional care of the local medical men. The committee were of opinion that, notwithstanding the large number of attendances in the out-patient departments of the general hospitals, those institutions had hitherto increased their accommodation and qualified staffs to an extent sufficient to enable them to cope with all such cases. The committee also thought that there was not any serious abuse of the out-patient departments in the general hospitals, and that any which might exist at the present time could be

effectually met by an efficient system of investigation, conducted by a competent staff in the out-patient department, who should visit the homes of the patients, and for that purpose the addresses of all out-patients should be taken. The committee had considered it advisable to confine its investigation to the general hospitals only, and not to the special ones.—Sir William Church moved that the report should be adopted, circulated among all the hospitals, and sent to the Press. After a short discussion the report was adopted. A resolution was passed to authorise the council to take steps for the incorporation of the fund. It was stated that a meeting of secretaries of London hospitals held the previous day at the Mansion House in order to devise a uniform system of accounts had appointed a committee for the furtherance of that object.

Medical Sickness and Accident Society.

THE usual monthly meeting of the executive committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429, Strand, London, W.C., on February 23rd. The chair was taken by Dr. de Havilland Hall, and there were also present Dr. J. Pickett, Dr. J. Rundley James, Mr. Edward Bartlett, Dr. St. Clair B. Shadwell, Mr. William Thomas, Mr. J. F. Colyer, Dr. F. S. Palmer, and Dr. J. B. Ball. The past winter has been unusually favourable to the society. For many years past the amount of sick pay disbursed during the winter months has been considerably in excess of the average of the whole year while the light experience of the summer has balanced this leaving a margin in favour of the society. But since the beginning of December last the claims received have amounted to less than the average expectation of the whole year and thus a profit has been made at a time when a considerable loss is usually sustained. The number of new entrants is also very good, and on the whole the year 1906 has opened very favourably for the society. Prospectuses and all other information on application to Mr. F. Addiscott, Sec. Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

Meat Inspection in the United States.

CONSUMERS of American meat imported to this country will be somewhat reassured after the recent attacks by a contemporary, with the result of an inquiry by the *New York Medical Journal*, which suggested that its English contemporary had to some extent been misinformed, particularly as to the data on which it founded its statement that only hogs were inspected, and, of those animals, only such as were destined to be exported to Continental Europe, those intended for Great Britain and for home consumption going entirely without inspection. The "Twenty-first Annual Report of the Bureau of Animal Industry," has been received, from which it appears that during the year there were 64,613,383 inspections of animals previous to their slaughter—namely, 12,599,831 of cattle, 14,633,129 of sheep, 1,143,962 of calves, and 36,236,461 of hogs. The *post-mortem* inspections amounted to 39,590,370, including 6,383,080 of cattle, 8,269,133 of sheep, 767,927 of calves, and 24,170,230 of hogs. Of the living animals, there were rejected (subject to the results of *post-mortem* examination): At the abattoirs, 757 cattle, 1,230 sheep, 500 calves, and 3,807 hogs; and in the stock yards, 42,263 cattle, 12,442 sheep, 6,555 calves, and 59,519 hogs. The numbers of carcasses condemned were 16,145 of cattle, 8,414 of sheep, 2,129 of calves, and 62,487 of hogs. This effectually disposes of the contention that only hogs are examined. The United Kingdom certainly is not wholly neglected by its own inspectors, as representatives of the Bureau of Animal Industry inspected 380,365 living cattle and 270,066 living sheep from the United States and Canada, the inspections being conducted at London, Liverpool, and Glasgow. The special microscopical examination of pigs for trichina is of course unnecessary in this country as the public do not eat raw flesh as in Germany, but it is gratifying to note that meat inspection generally is so efficiently carried out on both sides of the herring pond

The "Sanitas" Company.

AT the twenty-eighth Annual General Meeting of this company, held on Thursday last, Mr. C. T. Kingzett F.I.C., F.C.S., presiding, the Chairman stated that the sales for the year 1905 slightly exceeded those of the best previous year, and the profits allowed of the usual final dividend and bonus, making a total distribution for the year of 7½ per cent. The Chairman remarked upon the steady growth of "Sanitas" in public favour and in that of the medical profession, and while it was still regarded, from an all-round point of view, as a standard disinfectant (being the only preparation which combined in itself all the properties that could be desired for sick-room and household applications), it was necessary for the Company to meet competition from all sides. Hence, as the result of long investigation in their laboratories, the Company was about to introduce a new disinfectant to be known as "Bactox," which would favourably compare with the strongest known bactericides hitherto available, having a guaranteed co-efficiency of from 13 to 40 as compared with pure carbolic acid. It was described as a neutral non-corrosive, saponaceous preparation, and having regard to its great germicidal strength and price would be found cheaper in use and as strong as, or stronger, than any competing article on the market, and devoid of all objectionable qualities. They would, therefore, in future, be able to offer to the public and sanitary authorities the choice of the best disinfectant for household and sick-room purposes on the one hand, and the strongest germicide for rough disinfecting and surgical use on the other hand.

The Forthcoming International Congress of Medicine at Lisbon.

WE are asked by the National Committee for Great Britain and Ireland to state that the executive committee have secured a considerable number of rooms, some single bedded, but for the most part with several beds in a room at a cost of six, eight and ten francs a bed per night. There are also a few boarding houses which will take in members at a cost of fifteen francs a head. Tickets for these lodgings will be obtainable at the Rocio Station, which is the terminus for passengers arriving in Lisbon by train, and visitors are required to pay for the whole eight days during which the Congress lasts. Accommodation will be reserved in strict accordance with the priority of application made to Mr. Manuel Jose da Silva, Palacio Foz, Praca dos Restauradores, Lisbon. The hotels and restaurants as well as the buffet in the Congress buildings will solve the difficulty of obtaining meals.

The Cancer Hospital, London.

THE fifty-fifth annual meeting of the Governors of this charity was held on Wednesday last; Lieut.-Col. Parr presiding. From the report of the Committee it appeared that during the year 1905 there were 713 new in-patients, and 1,693 out-patients, with a total number of visits of 18,405, and the daily average number of beds occupied was 88. Owing to the deficiency of the ordinary income, it was found necessary during the year to realise between £4,000 and £5,000 from the capital to meet the expenses. The sanitary and hygienic condition of the hospital had been thoroughly investigated, and many renovations and additions carried out, one result of the additions being that nine more beds have been placed at the disposal of the surgeons, bringing the total number available up to 114 as against 105.

MR. AND MRS. ETHELBERG HOSKING, of Turner's Hill, East Grinstead, were last week presented with a handsome testimonial on the occasion of the silver anniversary of their wedding.

£1,100 has been realised by the Exhibition of His Majesty's battleship "Black Prince," which, by the kindness of the Thames Ironworks Shipbuilding and Engineering Co., was recently on view for the benefit of the Seamen's Hospital Society, also Poplar and West Ham Hospitals. During the three afternoons the vessel was open it was visited by the very large number of over 21,000 persons.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.
RECENT SURGICAL LITERATURE.

Cervical Rib with Resulting Gangrene of the Fingers.—Babcock (*St. Louis Med. and Surg. Journ.*, Dec., 1905) describes the case of a farmer, *æt.* 22, on whom he operated and removed a right cervical rib. On careful palpation, a deep-lying bony rod was felt running from the right lateral aspect of the seventh cervical vertebra downwards and forwards, passing under the clavicle near the junction of the inner and middle thirds. Since the patient was thirteen years old, every winter his right arm became pale, cold, numb, and useless. Recently the distal phalanx of the right middle finger had become gangrenous and the bone dry and exposed. The tips of the third and fourth fingers were affected to a lesser degree. There was no evidence of active inflammatory reaction. The entire right arm was smaller than the left, and no radial or ulnar pulse could be made out. The patient constantly assumed a position with the head inclined to the right side, the shoulder elevated and carried forwards, and the arm close to and across the body. Any other position caused him great pain. Pain was sometimes so severe at night, that the patient was obliged to walk the floor. The abnormal rib was reached by a transverse incision over the centre of the clavicle, and was found to be attached to the first true rib by firm, bony union. The cervical rib was divided at its centre and each half removed separately. The day following the operation, throbbing and burning pain developed in the right hand, which became red and warm. The pain soon disappeared, and on the third night the patient slept without an anodyne for the first time for several months. On the tenth day a faint radial pulse developed. The tips of the fingers subsequently dropped off, leaving healthy tissue. The author believes that the ischæmia so often associated with cervical rib is not caused so much by compression, but results rather from retardation of the blood flow due to tortuosity of the subclavian artery. The cervical rib, which is always present at the outer side and below the artery, tends to produce three rather sharp curves in it, one round the scalenus anticus, the second round the anterior portion of the cervical rib, and the third where the artery passes under the clavicle from a higher level and nearer the middle line than in the normal position (when the thorax and clavicle are not in such close proximity).

S.

Hereditary Syphilis.—R. W. Taylor (*New York Med. Journ.*, Feb. 3rd, 1906) reports two series of cases, all patients of his own, to further substantiate the fact that syphilis occurring in the grandparent may, without further syphilitic infection, be transmitted as hereditary syphilis to the grandchild. As support to his evidence, he quotes fully the cases recorded by Jonathan Hutchinson (two), and by Casar Boeck (one), as in the author's opinion no department of heredo-syphilis presents more doubt, uncertainty, and scepticism, than in the question whether syphilis can occur in three successive generations. *Case I.*—The grandmother was affected with syphilis in 1869, and had secondary and tertiary lesions of much severity. She was careless of treatment. In 1872, this first genitor gave birth to a girl who presented classical hereditary syphilitic symptoms. This child, after many vicissitudes, grew up an apparently healthy and strong woman. She was married to a healthy man, well known to the author, and never was infected with acquired syphilis. In 1890, two years after her marriage, this woman, the second genitor, gave birth to a weakly girl (third generation), who at birth gave no distinct evidence of hereditary

syphilis. But in five years this child suffered from an unmistakable and virulent form of late syphilitic manifestations, viz., Hutchinson's teeth, keratitis, gummatous tumours, &c. *Case II.*—A healthy woman married a man who was syphilitic for two years. She contracted syphilis two years later, coincident with the development of pregnancy. A male child was born, soon showing characteristic hereditary syphilis; the symptoms continuing for several years. He, the second genitor, was never infected with acquired syphilis, and married a healthy girl. Three years after the marriage his wife gave birth to a thin, weakly girl. Four years later, many dystrophic symptoms of bones and joints developed in this child, and were promptly cured by active anti-syphilitic treatment. The author also reports a case of hereditary syphilis cured by anti-syphilitic treatment, who subsequently was infected with acquired syphilis.
